"Lizzie" has been exposed as an old fraud. Her high-priced model bee-hive is a very *small* model, and a *full sized* hive, made after this pattern, is no better than any common movable-comb hive. She has for many years swindled the gullible bee-keepers so persistently that even her sex was questioned. Has she now turned over a new leaf? Has she become honest? The change is almost too sudden. Let our friends steer clear of her.

STRONG SWARMS ROBbing WEAK ONES.

This used to annoy me very much. I could find no effective remedy in A B C or GLEANINGS, so I hit on this plan: Watch where the robbers go, then change the hives; put the robbers' hive in place of the one being robbed, and the other in their place, then you will see how bad they will be beat. This may be an old plan; if so, I have not seen it.

TO GET THE COMBS BUILT DOWN TO THE BOTTOM-BAR.

I raise the hive up about one inch from bottom-board.

ISAAC WYKOFF, 17-42.

Cameron, Pa., April 23, 1885.

Friend W., your plan of exchanging places with a weak and strong colony when they are robbing is an old idea. It usually answers well, I believe, but sometimes it does not do at all, and it is always a severe shock to the prosperity of a strong colony. On this latter account I should hardly want to advise it as a rule, especially if the robbed colony is very weak in numbers.—Your plan of getting combs clear down to the bottom-board is all right. The same idea has been suggested in our columns before, but not quite as you put it. We accomplished it by raising the frames, and you raised the whole

hive. This could be done nicely with the Simplicity hive by turning the bottom-board hollow side upward. Separate them a little at one end to make an entrance, and when your combs are built down to suit you, put them back in their proper place.

CARP-PONDS: WILL THEY PAY?

I should like to inquire a little in regard to carp fish. Your pond is how large, and how do the little fish get along? But the most necessary thing for me to know is, Does it really pay to spend \$200 to build a pond about 70 feet square, or, in other words, can we really expect to get that money out again? If so, how soon? The above is a most important question, as I intend to make one, and it will cost me that much to get it done.

D. E. BEST.

Best's, Pa., April 6, 1885.

No, my friend, I do not think it will pay. Our carp-pond is larger than you mention, but it was made from a piece of waste ground that was of no value whatever, and the total expense was less than one-fourth of \$200. I would not advise anybody to make a pond at the present time, in the present state of our information, with the idea of making money. If you can use the pond for other purposes, such as a skating-rink for the children in winter, a place to get ice for summer, or by way of ornamenting your grounds, it may pay indirectly; but I should say that \$200 would be a pretty good price for a pond of the dimensions you name. With proper tools and a team, a pond can often be built during a time when you would not be likely to do much else.

BEES WORKING ON FRUIT-BLOOM AND RAPE AT THE SAME TIME.

My bees are now gathering honey from fruit-bloom and rape.

C. R. SCHMELTZER.

Scholl's Ferry, Oregon, April 7, 1885.

From the above report it would seem that rape can be made to bloom very early in the spring; or, at least, it is practical in Oregon. Now the question comes up, What is the difference between this rape and the seven-top turnip? or is not this kind of rape that blossoms so early what we call winter rape? and is it not identical with seven-top turnip? I have seen both in bloom on our grounds at the same time, and I could discover no difference.

GIVING BEES WATER IN THE COMB DURING SHIPPING.

When shipping bees I give them water differently from anything I have ever heard of. You advise sending nine frames. I send ten. I put water in one of them the same as G. M. Doolittle puts in syrup for feeding. You can put in a pint of water, more or less, according to the distance they have to go. It's the best of any thing I ever tried, but perhaps it's old with you.

I wish you would tell us in GLEANINGS how you bend your tin rabbets for hives. I don't find any one who can fold them with a tin-folder, but that makes them round on the bottom.

D. S. BASSETT.

Farnumsville, Mass.

Friend B., we tried your plan some years ago; but as the most of our shipping is done at a time when bees are gathering new honey, we have hardly thought it necessary, for new honey generally contains a large

quantity of water; in fact, it often runs out of the combs on to our clothing, when the combs are tipped sidewise. At times, when the honey is all old and sealed, I should think very likely a supply of water would be an advantage, especially during hot weather.—A good tinner's folder will fold the rabbits all right; but a folder that is made strong enough and accurate enough to do it properly, costs \$30.00 or \$40.00. If the rabbits are slightly rounded on the bottom, it does not matter materially.

MAKING DARK HONEY WHITE.

I read a short time ago in a newspaper, that in sugar-refineries the syrup is filtered through animal charcoal, and by this process the syrup lost its color. Will you please ascertain if this report is correct? and also ascertain the exact way to proceed, and the cost of this process? Please attend to this matter, and give results in GLEANINGS. We have a great deal of colored honey (No. 1 in quality), but unsalable on account of color, and if a cheap process can be ascertained it will add thousands of dollars to the earnings of bee-keepers.

Mauston, Wis., Apr. 14, 1885. CHAS. H. GROTE.

I believe it is a fact, friend G., that sugar-refiners do remove the coloring matter from syrup by filtering it through animal charcoal. I do not know whether the idea is possible with honey or not; but I agree with you, that it would be a most desirable process if possible. Have we, among our readers, any one sufficiently acquainted with sugar refining to answer friend G.'s question?

BEE-KEEPING AS A BUSINESS.

I happened to be writing to one of my old A B C scholars; and as I had not heard of him for some time I asked him if he was still a bee-man. The following is his reply, and there seems to be a moral in it:

As for being a "bee-man," I came as near getting over it this winter as I ever did. They "friz." Now don't tell me to fix 'em up warm in chaff hives, etc. I know all that. When I lose bees it is always the colonies that are seemingly strongest and best prepared for winter. The strongest swarm I have now was in one-story Simplicity, no cushion, several holes in cover; late swarm. I do not talk and write as much about bees as formerly, but like them as well as ever, and make them pay their way. It is easier to get 100 lbs. per colony, than it used to be to get 25 lbs., because of "the know how." It seems at times as if bees were the best stock a man can keep; at other times they seem a mystery, a delusion, and a snare. But for all that I expect to own a few colonies as long as I perambulate this little ball of mud. I'm not sure but I'll get some of A. J. Root's cheap big baskets to winter them in; take bees out of hive on to bottom-board, turn basket over them, and winter all right. See?

Remson Corners, O., Apr. 15, 1885. S. LUCAS.

Friend L., the point you make, that bees winter with a hive full of openings, when they do not winter with the best of protection, has been made several times, and I think it points out pretty clearly that you have been packing your bees too closely. Put loose chaff and nothing more over the frames; or if that is not sufficiently porous, fill the upper story of the chaff hive with

forest-leaves, dry and loose. To prevent the bees from getting up among the leaves, I would use a burlap sheet. May be the cheap big baskets would answer better than some of the hives you have been using.

A LITTLE STORY WITH A MORAL.

When the postmaster saw the last metal block come he dived down into a box and brought up another. It seems it had got lost out of the package of metal corners, and he had not known whom it was for, so it lay in the office all the time. If I had asked him for it he would have given it to me.

ALBERT W. HINDE.

Anaheim, Cal., Mar. 31, 1885.

I suppose that most of you have had experience in inquiring for things both at express offices and postoffices, and being told they were not there, and it afterward transpired that the same thing had been waiting for an owner for some time. One of the hardest things to manage I have ever found, in almost any department of business, is to avoid the accumulation of rubbish. Sometimes I go into the counter store and find a variety of odd traps stuck here and there. When the clerks are called, sometimes they reply, "Why, it has been lying around here this long while;" and in spite of every thing I can do, we have this state of affairs over and over. At the very time that they were tolerating or harboring this accumulation of rubbish, somebody was suffering sadly for the need of the very article. We try to tie up all packages so that it is almost impossible for the label or address to get detached; but for all that, they do sometimes get astray in the mail-bags. Now, if I were looking and waiting for something as you were, friend H., I would go to my postmaster and say something like this: "I have been watching and waiting very anxiously for a little square piece of iron that was to come through the mails. You have not come across any such thing 'lying around loose,' have you?" A great many times such an explanation will bring the missing thing to light where you would not find it otherwise. The same is true of the express business.

KIND WORDS IN REGARD TO BURMAH.

Great streams from little fountains flow,
Great oaks from little acorns grow.

I am reminded of the value of little things very forcibly by reading those letters from our missionary brother in Burmah. Some four years ago I asked you to send GLEANINGS to him, which you kindly did. That, like a little seed, dropped on fertile soil, sprang up, and lo! from this we have the "Pioneer Apiary of Burmah" already fully under way, with unlimited possibilities of usefulness in developing an industry which may be made of great value to the benighted race. It is a great pleasure to read Bro. Bunker's good letters, and to think that we helped him—just a little—to get started. Let's shake hands, Bro. Root, and all rejoice together. Let us not neglect, "as we have opportunity," to drop a seed now and then, in out-of-the-way places, which may "bear wheat, perchance some other grain."

In pursuance of this thought I have rolled up a package of Sunday-school papers to send out to a desolate home in the wilds of the Elk Mountains, of Colorado. Two little girls of ten and twelve years

live there with a drunken father, far away from school or neighbors or Christian influence. I hope the roll of pretty papers may brighten those sad little faces and cheer their dreary life a trifle. How I came to know of them would take too long to tell, and be a story in itself.

Our bees did rather poorly last season in the way of surplus. The heavy and continued rains seemed to wash the sweet all out of the flowers. This has been a hard winter so far, and many bees have "turned up their little toes." We went into winter quarters with 50 colonies. CLARA BUNKER.

El Dara, Ill.

A HINT OR TWO ON WINTERING.

I had last fall 35 colonies that I started to winter, and I have now 25. I let them alone until March 4, when it had been warm for two days, and I thought I must look some of them over. I found them all alive, with a few without any honey near the cluster; those, I moved the outside combs up near the bees so they could reach the honey. That night it came off cold, and remained so for the rest of the month. April 1st I found that four had died (three whose honey I moved), and two more ready to go, with only a few bees and a queen, which I couldn't save. It was warm about the middle of April, and I found four colonies dwindling. I tried to save them by adding hatching brood, but it was of no use, for it came around cold again, and most of the brood was lost (the bees were dying very fast, and there were not bees enough to cover the brood). Don't advise putting brood to weak colonies in a cold spring; better form a nucleus by taking one or two frames of hatching brood covered with bees, and shut them up in a good warm hive with division-boards, in a snug place for three days, and then put them in your dwindling colony.

The bees that I lost were from late August and September queens, except two that I disturbed every day in March, by going after hens' eggs in the leaves beside the hive. The honey in the others, although there was enough, was too scattering. The hives were my chaff hives. I shall see to it in the future, that my bees have sealed sugar or honey in every frame to the bottom, and then be contented until warm weather before I look at them. I moved my bees last November to where I now live, so that had something to do about the loss. J. L. HYDE.

Pomfret Landing, Ct., May 18, 1885.

"BE YE NOT WEARY," ETC.

I noticed friend Waterhouse, in GLEANINGS OF Apr. 15, says he can produce as cheap and good extracted honey as any one. Well, he deserves it, because he went through his tribulation and apprenticeship without getting discouraged, and comfort is his reward. CHAS. GUTEKUNST.

Bayou Chene, La., April 27, 1885.

What you say, friend G., is simply another way of expressing the old Bible promise that I have started at the head of this.

HIBERNATION: DOES IT INJURE A BEE TO BE THAWED OUT QUICK?

I read Mr. Doolittle's article on the hibernation theory with much interest. I think that perhaps it's not quite complete. In the first place I don't think that a frozen bee or insect of any kind can be handled carefully enough to be free from injury while frozen hard. Second, thawing them out too rapidly seems to be an injury. Just think of how very cold our fingers feel when warmed too fast;

then how different when bathed in cold water. An apple can't be frozen hard enough to injure it here at 40° below zero, provided it is three weeks or a month in thawing out. Then one that is thawed out in two days will turn black, and is then spoiled. If a bee's whole body hurts all over when quickly thawed as my fingers have when quickly warmed, I don't wonder at his dying before he is limber enough to kick.

JOHN NORRIS.

Manchester, Ohio.

Friend N., I have often thought of the point you make, but I am inclined to think that it does not hurt a bee to be thawed out as it does a human being; for bees, when warmed up, after being chilled, seem to be just as good as ever in an hour or two.—For a long time I doubted the fact you mention, in regard to apples; but last winter we had turnips frozen as hard as they could be, for months. They were lying on the ground, covered with straw; and when fully thawed out in that position they were as good as those that were never frozen. May be it will not always work, and may be it does not work with all sorts of turnips. Who can tell us?

CAN A CHRISTIAN CONSISTENTLY SELL TOBACCO?

The *Sunday-School Times*, in discussing the above question, which was propounded to them by a Massachusetts subscriber, replies as follows:

A Jerseyman was seen gathering some wild mushrooms in the woods. "Look here, my friend," said the passer-by, "those mushrooms are rank poison. You'd better let 'em alone." "Oh! don't be afraid," was the quick response. "I ain't picking 'em to eat. I'm picking 'em to sell." But those are mushrooms, and that was in New Jersey. About selling tobacco in Massachusetts, we would rather not express an opinion.

HEDDON COVERS, ONCE MORE.

I see that you and some others fear that the Heddon covers may be easily blown off the hives. I have used these covers two years, and have never had one displaced by the wind, although I have used no weights of any kind. The bees fasten them with propolis in a few hours, so that it is impossible for the wind to lift them off. They are the lightest covers I have ever used, and the easiest taken off and replaced. I think that about 75 per cent of the bees in this locality will be dead May 1st.

Bloomington, Ills., Apr. 4, 1885. R. I. BARBER.

Thank you, friend B.; but if your bees fasten the covers down with propolis so the wind can not blow them off, they certainly can not slide on to the hives in the way friend H. describes; and if so, how can you put them down into place, unless a very great deal of time be taken, without killing bees?

PHOTOGRAPH OF THE MEMBERS OF THE BEE-KEEPERS' CONGRESS.

Can we not hit on some plan to number and name the bee-keepers of N. O. Bee-Congress photo? I can name 22 of them correctly from memory, and would like to get the rest. JAS. A. NELSON.

Wyandott, Kansas, April 18, 1885.

Friend N., what you speak of would be very desirable indeed, if it could be managed. Perhaps I may explain to our readers, that toward the close of the session it was suggested that the entire lot of bee-keepers present in New Orleans should group them-

selves together on the grass and have our photographs taken. When the question came up, the matter of identifying the different members composing the picture was mentioned, and I called upon the photographer and explained to him fully how we managed it with the bee-keepers' medley; viz., by affixing a number on the negative so that the different individuals would be all numbered, making it possible for an explanatory key to give the name and residence. There was, however, some difficulty with the artist about the matter, and the pictures are sent out without being numbered. Now the question is, Can a printed slip be so arranged as to designate each person, as it is? I confess I do not see just how to manage it where there are so many different people.

A NEW TRICK FOR DISCIPLES OF IZAAK WALTON.

We have a friend of yours in this country, John Ross by name; he is a member of the M. E. Church South, a good bee-man, and an active farmer—a Nimrod of a hunter, and a pretty good member of the Church; but his last trick is new to me. He lives on the bank of Oyster Creek; the trees overhang the water, and John likes fish, but is too fidgety to fish for them, so he baits his hook and ties the fishing-line to the limb of a live-oak, and ties a cow-bell to the end of the limb. When the fish gets hung on the hook it rings the bell, and John gets up out of bed and takes the fish out of the wet (he sets his line at night). Isn't he smart? G. H. PHAIR.

Velasco, Texas.

Many thanks, friend P. The idea is ingenious; and from what experience I have had I do not see why it would not work. If one could spare the time, his chances would probably be a little better to have control of the line about the time Mr. Fish was getting hooked on; but by having several lines arranged as you mention, I think it might work pretty fairly in a proper locality.

A BROTHER IN TROUBLE.

Too many bees! what shall I do with my bees? My hives are so full of bees and honey that I know not what to do with them. There is not much sale for them in this section, and I have as many colonies as I wish to keep, and I think they will all swarm this season, so I am thinking what is best to do with them. I wish that some of the bee-keepers who have so many empty combs had some of my Italians. Their combs would not be empty a great while.

ALBERT G. BRUSH.

Susquehanna, Pa., April 27, 1885.

Dear me, friend B., what a queer lot we are! Some of us are in great trouble because we have not any bees at all, and others are in great trouble because they have so many. What shall you do? Why, divide up with the sufferers, of course, and make the prices as reasonable as you can. Sell them off by the pound; and if you can raise some queens to go with them, it would help all around.

FASTENING THE BEES INTO HIVES WITH WIRE CLOTH FOR CELLAR WINTERING.

We put 26 colonies in cellar, and packed 6 in Root chaff hives on summer stands. The 26 colonies wintered in the cellar are now all alive, with hives full of bees. We wintered in a cellar of 40°, with venti-

lation through the hive, by covering the bottom with wire screen, and raising the cap $\frac{1}{4}$ inch, with one corner of mat thrown back. One hive, where we did not raise the cover, lost nearly as many bees as the other 25, although in other respects put up in the same way. Our chaff hives were contracted to 7 frames, with thin division-boards on each side, chaff between boards and side of hive, upper story filled with chaff, all alive and brooding March first; four dead with dysentery April first. There were but few days in March when the temperature was above zero, and it was down to 26° below during the month. Conclusion: We have decided to winter our bees in the cellar, with 40° of heat, ventilation through hive, wire screen on bottom, both top and bottom ventilation for cellar, with plenty of wholesome sealed honey, and I think we can then stand the most severe winter of this climate. We can't rely on chaff hives here, although we have had bees winter nicely in them heretofore. I don't see that pollen makes any difference in the cellar, as there was no apparent difference in those with and without, excepting brood. J. J. HOLLENBECK.

Saratoga Springs, N. Y., Apr. 25, 1885.

ATTACHMENT FOR BARNES SAW.

A strip of ash, $\frac{1}{4}$ in. thick, $1\frac{1}{4}$ in. wide, and 4 ft. long, with one end fastened to the top of the cut-off gauge by two screws can be used as an extension, either to the right or left, and a stop can be fastened almost instantly at any point by a small iron clump, which any blacksmith ought to make for 10 cents. I have used this sort of an extension to the cut-off gauge for 4 or 5 years.

E. Springfield, O.

R. M. REYNOLDS.

We have many times used something quite similar to what you describe, friend R.

FRIEND MUTH COMMENTS A LITTLE ON THE GENERAL DEPRESSION IN THE SUPPLY BUSINESS.

It appears that you experience, as we do, a very dull season. It was with us, last winter, too much honey on hand and too large a capital invested with too slow a demand for the article. There is no demand for honey now but from our regular customers who had taken a rest last winter. Last year, about this time we were shipping 500 to 1000 bee-hives per week, while we don't ship 100 hives now. Matters will take a change again after awhile, as has always been the case; we have, therefore, to exercise a Christian patience. CHAS. F. MUTH.

Cincinnati, O., May 15, 1885.

A HOME-MADE TELEPHONE THAT WILL WORK HALF A MILE.

If you want a telephone that will work 1200 or 1300 feet, here is one. Take a piece of green calf-skin, and dress it the same as you would for a drum-head. Take a one or two quart measure, wooden, and stretch the skin on tight while green. In fact, make a drum-head of it. One measure will make both. Put the wire through the center of your drum-head, and fasten to a wooden button, and you will have a telephone that will work half a mile. E. A. ROBINSON.

Exeter, Maine, April 8, 1885.

No doubt, friend R., a telephone as described above would work as well as any in the market. The first telephone we used was much like the one you have described, and I believe it gave about as good results as any we have had since.

DRY FECEES, AGAIN.

I have just received from Dr. C. C. Miller some long, cylindrical, dark-colored masses, some bent, some straight, and some constricted so as to appear bead-like. The accompanying drawings represent the bent and constricted ones, and are magnified

BEE-FECEES.

They break up at once when put on a glass slide with water, as do all bee-feces when dry; do not melt with heat, are not dissolved in alcohol and ether; and as they break up in water they are found to be composed wholly or almost wholly of pollen grains. In some I found quite a number of hairs and other fibers.

As stated in my address at Cincinnati on this subject (see *A. B. J.*, 1882, p. 626), fecal matter in bees is semi-solid. Of course, the liquid may be less on occasion, as we find in all animals. I have never seen such solid fecal pellets from bees as these before, but am not surprised that they may exist. In all animals, the fecal excreta varies much at times in its consistency.

This is not the "dry feces" so much talked of in our papers. That is the matter dropped by bees in their winter quiet; and, as shown in the article just mentioned, is wax and other matter kneaded by the bees by use of their jaws, and dropped as pellets to the bottom of the hive.

A. J. COOK.

Agricultural College, Mich.

TWO OR MORE EGGS IN A CELL.

I have seen along in the bee-papers, that a queen always lays but one egg in a cell, but that a worker will lay more eggs than one in a cell; and also that a laying worker is developed only in the absence of a queen. To-day I was overhauling my bees, and I was astonished to see about a dozen cells contiguous that had three eggs each, mostly sticking to the sides near the bottom; and yet within three or four inches of these cells was a fine queen moving about as usual over the comb and among the bees.

Baltimore, Md., May 20, 1885.

C. GARWOOD.

One egg in a cell is the rule, friend G.; but, as is usual with bees, there are a good many exceptions. Where a vigorous queen has but a small cluster of bees, she will often go around and lay eggs in the same cells over again, for want of some better employment, and in that case it indicates nothing wrong. Give her a couple of pounds of young bees to provide empty cells for her, and she will put one egg in a cell as nice as can be. A good fertile queen should, however, stick each egg in pretty nearly the center of the bottom of the cell. If they are sticking along the sides of the cell, near the bottom, as you say, it usually indicates something wrong, and the queen often does this kind of work just before she plays out entirely. Fertile workers lay great numbers of eggs in a cell—sometimes a hundred or more, and very often

they stick them around the sides of the cells, on top of the combs, etc. In rare cases, however, they deposit them regularly, filling the cells as they go along. A good queen fills the cells regularly as she goes along; and where the cells are skipped here and there, we generally have pretty good reason for suspecting that it is the work of a fertile worker. If several eggs are in one cell, and none in another, the evidence is still more conclusive of a fertile worker, or a queen that does not amount to much.

SLATTED HONEY-BOARDS.

I invented and used a slatted honey-board long before I heard or read of a Heddon honey-board. I just nailed slats on to end-pieces to keep the bees from building combs between the top of brood-frames and the bottom of wide, or section frames, and it does well. Said end-pieces rest on the ends of brood-frames, and leave a bee space all around between honey-board and hive.

COMB-FRAME STAND.

One of the simple but very useful things in my apiary and extracting-room, that I invented and never have seen or heard of in any other apiary, is a little like a light low stand without top-board, made to hold a set of wide or brood-frames. I use two of them.

D. TYRRELL, M. D.

Toulon, Ill., May 18, 1885.

LIVED IN SPITE OF BAD TREATMENT.

The first of last July I purchased 12 hives of black bees, going 20 miles for them with a spring wagon. I commenced shutting them in as soon as they were all in in the evening, which was quite a job, as the hive-maker was not a workman, nor the hives of the most approved pattern. However, I got them shut in by nine o'clock P. M.; and to hasten matters I took strips of pine and nailed over the entrance and all cracks. A few had wire cloth over the entrance. I started for home at 4 A. M., and arrived at my destination at 12 o'clock noon, of one of the hottest days the summer can boast of, all in good condition. I am satisfied that there is too much ventilation given generally.

My Italians that are now the strongest, and consumed the least amount of honey, were covered entirely out of sight with snow for about six weeks. Some I kept enameled cloth covers on over winter, and I find them all right. In cellar, I would not care how much ventilation it had, if with warm air; but I would keep the hives closed. Bees have wintered fairly, as far as I have heard, in this country.

Bethlehem, Conn., May 6, 1885.

F. A. MALTBY.

Friend M., I should say that you got off remarkably well. We have all seen and read of hundreds of colonies that were entirely ruined by being shut up, apparently in the very way you closed those hives on that hot summer night. Probably the hives were so old, and had so many cracks through them, that they got sufficient air in spite of the way in which you fixed them. I should be inclined to think the colonies were not very strong, and that the hives were pretty good size. One of the first purchases I ever made was under circumstances a good deal like those you have mentioned; and although I moved them only across the town, the whole contents of the hive ran down into one heap, and the mass was almost scalding hot. My honey ran on to the

ground, and my bees were all lost, except a few that I washed off with water and dried in the sun, in a box covered with wire cloth.

HOW OUR FRIEND MRS. JENNIE CULP PREVENTS SWARMING.

In the May No. of GLEANINGS Mrs. Culp says, "As my object was honey and not increase, I prevented swarming." Now, that is just what I most want to know how to do. Will she not tell me, through GLEANINGS, just exactly *how* to do this, and perhaps thus oblige others as well as myself who are just beginning? My two swarms of Italians have wintered through nicely in chaff hives.

Fluvanna, N. Y.

SARAH M. BENTLY.

We forwarded the above to Mrs. Culp for an answer, and below is her reply:

My method to prevent swarming is to keep queen-cells pinched off, and give them plenty of working room. This can be done by tiering up, if you have the right kind of hive with movable frames, or by taking frames of brood from brood-chamber, and use them to build up weak colonies, then by giving them room. This the sister can not do if she has only two colonies.

JENNIE CULP.

Hilliard, Ohio.

MAKING SUGAR SYRUP WITHOUT BOILING.

I will decide with you as to making feed. I see that some think they can't make it without boiling. I will say, that that is all a notion. I have not had much experience in bee culture, but I fed about 4 gallons of syrup last fall, and I never boiled it, and it has not crystallized a bit. I think I can make it every time so it won't, and without boiling.

GEORGE M. GARNY.

Carver, Plymouth Co., Mass., May, 1885.

CALIFORNIA AND HER CAPABILITIES.

THAT 10,570 LBS. COMB HONEY FROM 18 STARVING COLONIES.

I SUPPOSE all the distinguished bee-keepers in the world, except myself, were at New Orleans. I should have liked to be there too, but that was impossible. I see by the papers that the large honey reports for last year, from this State, were doubted; or, rather, that many thought there must be some mistake. This is nothing more nor less than pronouncing them fraudulent. Now I am going to show you that *one* of the reports was true—true to the letter—except that it was not big enough.

Let me digress here, friend Root, to say that I do not believe that we yet half understand the capabilities of a swarm of bees, in tiptop condition, and floods of honey literally flowing down the mountains, as it did last year! I believe the time will come—and it may not be far away—when 1000 lbs. of honey may be got from a single colony and its progeny, in a single season. Lunatic, eh? Well, there is one consolation anyhow. The Stockton asylum is full, and they have not commenced the new one yet, and so they won't take me for a while. But, to return.

In proof of the above, there were two of our hives which gave us but about two section boxes—say 28 lbs., of honey. What their descendants did (if they

had any) is more than I can say. These two hives never swarmed that we knew of; and they made only about 28 or 30 lbs. of honey each. Now throw off the odd 70 lbs. for this, and you will find the average for each hive that *did* swarm was 656½ lbs. I do not wonder that bee-keepers are astonished, nor do I wonder that they doubt it. But because it never *was* done before, is no valid reason that it can not be done. You are old enough, and I am old enough to remember the time when, if we had gone round telling people that the time would come when we could talk to our friends 500 miles away, we would both have been looked up as lunatics! Here it is, you see. Men make a high-water mark, as it were, in their own minds. On this side of that mark lies the possible; but beyond lies the impossible. But they often have to move the mark a little more beyond. So it is in this case. You will have to move the mark, gentlemen, a little more beyond. Some of these 16 hives gave much more than others, so I must come to the conclusion that some of the old hives and their progeny gave as high as 800 lbs. of honey. Push the mark a little further on, gentlemen. Who will say, knowing the past and looking into the future, that no hive of bees and their progeny will ever make 1000 lbs. of honey in a single season?

And these are the dilatory, short-snouted, lazy Italians. They sleep too late in the morning; in fact, don't get up till after breakfast. They go to bed before sundown, and can't snatch it from red clover. Do they need some brown German blood in them? What do they need?

Now, dear friend Root, I want you to stand by us in our trouble, and tell us what to do. Reading over the advertisements in the bee-papers, we find that we have not got the right kind of bees at all. We have not got "the bees for business." They get up, and scratch gravel before daylight. They can fly faster, dive deeper, claw out and carry away more honey, than forty Italians. They never go to bed at all—no, never wink an eye. They have the brown German blood in them. Shall we get them?

Now let us go back to the honey crop. Below is the certificate of Messrs. Hamilton & Co., that they received in store from us 141 cases comb honey, averaging 56 lbs. to the case, which is equal to 7896 lbs.; now add 5½ cases here, 56 lbs., 308 lbs.; 68 hives containing 60 lbs. honey in brood-chamber, 4080 lbs.; 1 ton of section boxes, which was unsalable because the outer end was not sealed up. They are now on the hives again to be sealed up, 2000 lbs. Total, 14,284 lbs. Now deduct amount produced by the lower apiary, say 3480 lbs. Product of the home apiary, 10,804 lbs.

Now besides this we sent two cases to the Light-House, and one case to a lady friend in Los Angeles; these, making 168 lbs. more, were never counted. Also some 10 to 15 gallons of strained honey, which came from broken comb and crooked honey, that was likewise never counted. Gentlemen may stand agape, and wonder what is coming next. But I produce the certificate of receipt in store. I produce the certificate of the men who hauled the honey to town. I produce the evidence of my nephew, who helped to handle the honey, and who is familiar with every move and motion from the beginning to the end.

Now, gentlemen, go back to New Orleans and put your wise heads together, and resolve that there "must be some mistake about it." While you are

took a premium as long as I exhibited. I took it, ribbons and all, to one groceryman, and said, "If you will sell this honey for 25 cents per lb. I will agree to sell you all that I raise at 20c. per lb.; and if it does not sell I will take it back." Produce nice honey; keep your extracted honey until fall; put it up in Mason's fruit-jars, and just bring it in about as fast as he needs it. It is poor policy to force a market; just take a note how business men do in establishing a trade in towns: they simply, as a general rule, let one firm handle their goods. By the above plan I never failed to get 20c. per lb. net for extracted honey. Consumers would often say that they could get honey cheaper from large cities; but as they knew what they were getting, they did not object to the price. Also, do you know when you put your honey in those narrow $4\frac{1}{4} \times 4\frac{1}{4}$ sections that hold only 12 ounces, the producer getting pay for actual weight only, that you are robbing the consumer out of 4 ounces, or are the means, at least. Now for proof: You all can see what honey is worth in Kansas City, Mo. Now, a grocery dealer here sent to Kansas City for some comb section honey: it cost him 20c. per lb.; that is, each section was counted 1 lb. to him. He sold it for 25c. per section. They weighed only 12 oz. each. When I asked him he said they called it 1 lb., so he sold it by the section. Now, the commission men got the most benefit out of this honey, as they made 100 per cent, as you can easily count up. That is one reason they tell you that dealers prefer a light section under 1 lb.

H. F. HAGEN.

Ellinwood, Mo. Kansas, May 15, 1885.

Friend H., your suggestions are excellent in regard to putting up Simplicity hives. We try to have our lumber thoroughly seasoned before the hives are made; but every mechanic knows that, after lumber is dressed and cut up into small pieces, it will shrink considerably more; and the worst feature of this shrinking is, that the pieces shrink unequally. Your idea of selecting those of a width for each hive, before you commence nailing them up, is excellent. Another thing: If you can not find pieces exactly of a width—that is, suppose the end is a little narrower than the side to which it is to be nailed, be sure to let the side piece project equally beyond the end piece at both top and bottom. You need not argue with me about this matter, because I am old in these things. If you put them together so they are even at the top or even at the bottom, when you come to pile your hives up the crack left will be twice as wide as if the space were divided. Worse yet, if two hives having large spaces happen to come together it would make a space large enough to let bees out. By dividing the space as I have told you, there will be scarcely a possibility of any such mishap. These small openings in the Simplicity hive will do no harm, but, in fact, are a benefit, because no other provision for ventilation is made.—Your ideas in regard to keeping a uniform price on your honey are excellent. There are many articles of merchandise on which the manufacturer is absolutely obliged to control the retail price, to save his business. The new Ivory soap, for instance, that is advertised so extensively, the manufacturers sell to every dealer at a fixed uniform price. If he

takes a certain number of boxes, it is laid down at his door, freight paid. To prevent cutting under, and rivalry, every order must go through the hands of the nearest wholesale grocer. The soap goes in one fixed regular channel from the factory to the consumer, and there are no deviations. The plan you suggest in regard to it is the thing exactly.

SOME QUESTIONS FROM CALIFORNIA.

MAKING BEES WORK DOWN AS WELL AS UP, ETC.

I WANT to ask you a little about transferring some of my bees into my new Flory hive. Mr. Flory says I can set the old swarm on top of my new hive, and the queen will work down better than they will up. Now, I fail to find much about that in your A B C book. If I can transfer my bees by setting my new boxes under the old ones, that will save me lots of trouble; and if you will give me your advice on the matter, I shall be much obliged.

CHAFF HIVES IN CALIFORNIA.

What do you think about the chaff hive in California? Do you think it would pay out here? And how about something to lay on top of my frames, to keep the bees warm? Out here, people do not use anything to cover the bees but just the top board, and I think they would do much better if they were kept warm; that is the reason our bees are so backward about swarming out here. Our bees have been working a long time, and they do not swarm out much, yet I have two swarms from 33 stands of bees, and my neighbor Hobler has only four or five swarms this season, yet he has got his from Italian bees. Mine are blacks.

HIVES WITH FRAMES OF DIFFERENT SIZES.

The way my hives are, I can not take a frame out of my old hive and set it in my new swarm, because they will not fit; that is a drawback to me this season. If I can get them all in one kind of a box, it will be more plain work.

ALFALFA.

We have a big alfalfa crop out here this season. Last season was a poor one for them, but it has got to be a big business now in California as well as other parts of the world.

M. J. TWining.

Hanford, Cal., May 12, 1885.

Friend T., as a rule bees seem to prefer working up rather than down, although when crowded for room they will often fill an empty hive placed under the old one. If Mr. Flory has tried it, and finds that it works successfully, I should try one or two that way. In my opinion, however, they will have to be crowded more to get them to take the new hive than if you would put the new hive on top. Either mode is, however, rather behind the times.—You can not do any thing very well until you get your apiary in such shape that any frame will go into any hive.—In regard to chaff hives in California, the matter would have to be determined by actual experiment. If you have cool nights, so cool, in fact, that it drives the bees out of the surplus boxes, then chaff hives would be a great advantage at such times, and I think they would be an advantage during your hottest weather in protecting the bees from the direct rays of the sun.

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

A. I. ROOT,
EDITOR AND PUBLISHER.
MEDINA, O.

TERMS: \$1.00 PER YEAR, POSTPAID.

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, JUNE 1, 1885.

But foolish and unlearned questions avoid, knowing that they do gender strife. II. TIM. 2: 23.

OPERA-GLASSES FOR BEE-HUNTING.

We have ceased to keep the \$3.00 opera-glass, because the \$5.00 one proves to be so much better in quality of lenses, and workmanship of the whole instrument.

PRICES LOWER.

We have been enabled to reduce the price of so many commodities that perhaps it will pay you to have a new price list if you have not had one during the past thirty days.

THE MARBLE MONUMENT IN NEW ORLEANS TO THE MEMORY OF MARGARET.

FRIEND D. M. MCKENZIE INFORMS US that the marble statue to the memory of Margaret, mentioned in *Our Neighbors* for April 15, is the only monument in America, to the memory of a woman.

THE A B C OF CARP CULTURE.

THE delay on this work was caused by a dilatory engraver, and by the sickness of Mr. Peirce, the author. Of course, no one is to blame for being sick, and I did not intend to blame any one but myself, in the editorial comment on this subject last month. The worst part of it is, the book has not even yet put in an appearance.

BUSINESS JUNE 1.

We are all up with orders, and have been for almost a month past; in fact, you can have almost any thing you want by return mail, freight, or express. In some respects it is a pleasant way to do business; but I fear that many of the supply-dealers will have a pretty dull time unless they keep close to shore during the coming fall and winter.

OUR CARP-POND.

OUR thanks are due to friend Kaler for some beautiful specimens of German carp. They came to hand bright and lively, and are now enjoying themselves in our carp-pond with perhaps 130 or 140 more, in size from an inch to one foot or more in length. We have not been able to make them take their food yet. Perhaps the reason is, there is so much rubbish in the way of water-plants, soft mud, etc., that they have not yet had time to come down to a diet of bread and water.

CALLING THINGS BY THEIR RIGHT NAMES.

Is it any wonder that our clerks make mistakes sometimes in filling orders, when people will persist in using odd terms for what they want? Here is a specimen card:

Will you send me the book and the price of the tin hinges for the slats in the bees' boxes? Please send me a list of all about the bee-gram. JAC. L. SNOODGRASS.

Reed's Mill, Jeff. Co., Ohio, April 7, 1885

Now, if anybody can tell us what friend S. means

by "tinned hinges for the slats in the bees' boxes," we should like to have him stand up and enlighten us. We sent friend S. a prospectus of the A B C book, and a price list.

WHICH EXTREME SHALL WE CHOOSE. "TOO MANY EGGS IN ONE BASKET," OR "TOO MANY IRONS IN THE FIRE"?

QUITE a discussion has come up, and seems bound to come up, in regard to which is the better of two extremes—choosing a specialty for your occupation in life, or having a variety. It does not seem to me, dear friends, that there is any need of wasting a great amount of words over the matter. Where one goes too far to one of the extremes, his friends are in duty bound to urge strongly the merits of the other course, and this is true in any other thing as well as business. Some men are disposed to fall into ruts, and get so deep into their ruts that they can not see what is going on outside of their rut. Others are so prone to have so many irons in the fire that they need constant admonishing in regard to their besetting sin—the sin of scattering one's powers to so great an extent that he excels in nothing. In regard to the way GLEANINGS is managed, the preference of *by far* the greater part of its readers is, that it shall notice, to a reasonable extent of course, the new things that come up in kindred rural industries; that is, where one objects to taking up such a thing as carp culture, at least a dozen say, "Let us know about it;" and when something else comes up that farmers, professional men, and even merchants, who like to get out outdoors, are likely to get interested in, tell us about it. To satisfy the minority, it may be that it would be well if the reading on the cover should be changed to "Devoted to bees and honey, and other rural industries;" but it seems to me GLEANINGS may look over the fence occasionally, even if we don't put this in its head.

SENDING QUEENS BY MAIL FROM CALIFORNIA IN FEBRUARY.

I OMITTED to mention, at the proper time, that friend Norton did send us a queen, lively and in good order, all the way from Gonzales, Cal., during the month of February. The queen and bees were carefully packed with woolen cloth, so as to enable the cluster to keep the inside of the little cage warm, in spite of frost without. Accident may have favored the transit somewhat, perhaps, although a good deal is due to careful preparation. Now, friend N., if you can send queens safely to the States in February, why can't you supply the good people west of the Rocky Mountains with good queens all summer long? By getting an imported queen to breed from, you can furnish just as good stock as we do, and it is a great piece of folly for the friends in California to send clear here for queens by mail. May be there is something in the fact that we always have queens on our table, ready to go back by first mail; but, bless your hearts, can't some of the other brothers and sisters take advantage of this splendid means of advertising, as well as A. I. Root? What ever ails you, friends?

SENDING QUEENS PROMPTLY.

Just one little illustration of the trouble it makes by being behindhand on so simple a thing as a queen. A few days ago the orders were too numerous for us. One friend had to wait several days for an untested queen. We could not tell him just when it would be sent, because we did not know

how fast the brethren who were raising them for us down South were getting along. Well, even during those few days of delay he wrote us that he had traveled *thirty miles* in going to the postoffice and back again after his queen. He expected us to send the queen right straight back, as we always had done heretofore.

HEDDON'S HONEY-BEARD MADE FOR SIMPLICITY HIVES.

I AM sorry to say, that, through some unaccountable blunder, 300 or 400 of these have been sent out, having only 9 spaces instead of 10. It is true, you can use only 9 frames in a Simplicity hive, and some prefer to do so; but where we are working for comb honey, I would by all means have the combs trimmed so they will come down to the regular orthodox number of 10 combs for an L. hive. If the friends who have received these nine-space honey-boards will write us, we will try to make the matter satisfactory. They can easily be made right by drawing the nails and putting in an extra slat; or they can be used with 9 combs; or even if used as they are for 10 combs, I suppose there will not be much trouble by bees building up through them.

BEE-SWAX.

FOR the present, the best we would dare offer for good average beeswax is 24 cts. cash, or 28 cts. trade. This to take the place of the offer on the cover of this number.

WE are this 28th day of May notified that the ABC of Carp Culture has been shipped us from the publisher.

WE have to-day, May 28, 6465 subscribers.

CIRCULARS RECEIVED.

Arthur Todd, Philadelphia, Pa., sends us a nice 8-page price list of bees, hives, honey, etc., GLEANINGS size.

M. C. Von Dorn, Omaha, Neb., sends us a neat 6-page price list of standard apiarian supplies.

James O. Facey, Tavistock, Ontario, Canada, has issued a 4-page price list of queens and apiarian supplies.

C. Weeks, Clifton, Tenn., sends out a nas al price list of Italian queens.

Andrew Burward, Merriam, Wis., send us card price list of honey, hives, and bees.

T. S. Hall, Kirby's Creek, Mo., sends us a very nice 24-page price list of Italian bees and apiarian supplies.

Henry E. Fitz, Lynn, Mass., sends us an 8-page price list relative to the Champion bee hive.

G. W. Putnam, Holland, Iowa, sends us a 4-page list of apiarian supplies.

A. M. Gander, Adrian, Mich., sends us an 8-page list of bee-keepers' supplies.

W. Ballantine, Sugo, O., sends us a 16-page price list of queens and apiarian supplies.

CONVENTION NOTICES.

The Bee-keepers' Association of Central Illinois will meet at Bloomington on July 15th, at 10 o'clock A. M.

Bloomington, Ill., April 30, 1885.

The Southern Ill. Bee-keepers' Convention will be held in DuQuoin, in Esp. Reed's office, on Wednesday, June 10, 1885, at 10 A. M. A cordial invitation is given to all who are interested in bees.

W. LITTLE, Pres. F. H. KENNEDY, Sec.

GLEANINGS AS AN ADVERTISING MEDIUM.

The notice "Bees for Sale," you gave free in GLEANINGS, brought in one week more customers than I had bees. Thanks.

Vincennes, Ind., May 18, 1885.

I think GLEANINGS is a splendid medium to advertise through, as I have sold every swarm I have. Will you please say to the bee-keeping fraternity that I have no more bees for sale?

Milford, Wis., May 23, 1885.

J. R. REED.

1885. VALLEY APIARY. 1885.

PLEASANT VALLEY APIARY.

PURE

BRED

ITALIAN AND ALBINO QUEENS.

Untested, after June 1st..... \$1 00
 " " " " per dozen..... 5 00
 Tested progeny, three-banded..... 2 00
 " Selected, young, large and light-colored..... 3 00
 Full colonies in Langstroth or Simplicity hives..... 8 00
 Nuclei (no queens), 2-frame, \$2.25; 3-frame..... 3 00
 Celebrated poplar sections, per M. (sample mailed free)..... 5 50

All orders filled promptly, and safe arrival and satisfaction guaranteed. Full colonies have tested queens; nucleus colonies (add the price of queen). The above strains are bred in separate apiaries, home containing over 70 full colonies, all pure Italians. My strains have stood the test of hardiness; have always wintered on summer stands, and have not lost a colony in the past 4 winters. Sample of my large, handsome, light-colored workers sent for 10 cents. Address

E. L. WESCOTT, Fair Haven, Rutland Co., Vt.

THE KIND OF BEES YOU NEED.

IF you want bees for business, get those that will work on red clover. Not a colony of this strain lost in wintering since they originated. Circular free.

F. BOOTHOWER,
 111tdb Galupville, Schoharie Co., N. Y.

BEES FOR SALE.

HYBRIDS AND BLACKS, strong colonies, on 9 wired L. frames, delivered on Miss. River boat at \$4.00 per colony.

H. B. SHAW,
 11-12-13d Gum Ridge, Jeff. Co., Miss.

FOR SALE.

I will sell a limited number of 3-frame nuclei with dollar queens, bred from good stock, during the month of June, for \$3.75 each. Size of frame, 10x 14 inches. I shall aim to give satisfaction. Write to postmaster at Stanley for reference. Make money-orders payable at Bluffton, Ohio. Address

11 JACOB GUISINGER, STANLEY, PUTNAM CO., OHIO.

BEES FOR SALE.

Italians in brood-chamber, L. hive..... \$7 00

Hybrids..... 6 00

One pound Italians..... 1 00

One pound hybrids..... 75

Safe arrival guaranteed.

TOM PHELPS,
 11d Sonora, Hardin Co., Ky.

DADANT'S FOUNDATION FACTORY, WHOLESALE AND RETAIL. See advertisement in another column.

FOR SALE!

I WILL sell my apiary, consisting of 50 stands of Italians, honey-house, 20 acres of land, good for garden or fruit-growing, bog-raising, or cotton. For further particulars, address

ISAAC GUTTON, WACO, McLENNAN CO., TEX.

FOUNDATION MACHINES.

\$3.50, any size. Molded Idn., 40 to 50 cts. per pound. Italian queens in their purity, from the South, and of my own raising, untested, \$1.00; tested, \$2.00.

11d JOHN FARIS, TOWN HOUSE, SMYTH CO., VA.

THE UNDERSIGNED offers for sale very cheap a quantity of improved movable-comb hives, adapted to either outdoor or cellar wintering. For further particulars, address

11tdb ADIN A. SMITH, MOHAWK, HERR CO., N. Y.

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they want to dispose of, we will insert notices free of charge, as below. We do this because there is hardly value enough to these queens to pay for buying them up and keeping them in stock; and yet it is often times quite an accommodation to those who can not afford higher priced ones.

QUEENS FOR SALE.—Hybrid queens, 50 cts. each; black queens, 25c each, from June 1 to Oct. 1. Safe arrival guaranteed. R. H. BAILEY, 7-11db P. O. Box 81, Ausable Forks, Essex Co., N. Y.

A few hybrid queens for 50 cents in June. Black queens, as long as we can buy Blackswarms, for \$1c. Also a limited number of tested Italians for \$1.25, 2d class. We will ship all in the Safe cage and guarantee safe arrival only. After tested queens are out, will fill orders with untested. S. A. DYKE & Co., Pomeroy, O.

I can spare a limited number of hybrid queens the coming summer, reared from best imported and select tested Italian queens. By return mail, in the Peet shipping-cage. Safe arrival guaranteed for 50c each. Address JOHN A. THORNTON, Lima, Adams Co., Ill.

I am superseding a lot of good hybrid queens, which I will ship to any one for 50c each; safe arrival guaranteed. It is a pity to kill them. J. W. WINDER, Carrollton, New Orleans, La.

I have now for sale 23 hybrid queens at 40c each. Safe arrival guaranteed. J. H. JOHNSON, Middaighs, Northam. Co., Pa.

We have about 30 hybrid queens to dispose of; will take 50 cts. each, or in lots of five, 40c each. JOHN NEBEL & SON, High Hill, Mont. Co., Mo.

I have a few good hybrid queens for sale at 50 cts. each; also a few blacks at 25 cts. Ready now. FRANK A. EATON, Bluffton, Ohio.

I have 20 hybrid queens that are daughters of an imported mother, that I wish to sell at 50c each. J. F. McCORD, Covington, Newton Co., Ga.

WYANDOTTE EGGS

Price reduced for June only, \$1.75 for 13 eggs; \$3.00 for 26. The eggs hatch well. Mr. T. J. Young, of Austin, Ark., reports 20 chicks hatched from 26 eggs that I sent April 10.

PURE ITALIAN QUEENS sent for \$2.00 each. Every thing guaranteed to arrive safely. Circulars free. J. C. BOWMAN, 11ld North Lima, Mahoning Co., O.

I HAVE a few dollar queens ready now. Untested, \$1.00; Warranted, \$1.25 each. Also 6 tested queens, \$2.00. L. HEINE, BELLMORE, QUEENS CO., N. Y.

DADANT'S FOUNDATION FACTORY, WHOLESALE and RETAIL. See advertisement in another column. 3btfdd

The North-Shade Apiary

Full colonies in either the Langstroth or the Gallup hives, for May delivery. Nuclei, Queens, and bees by the pound, for the season. Price List Free. 8-9rtd O. H. TOWNSEND, ALAMO, CAL. CO., MICH.

QUEENS! QUEENS!!

Untested Italian Queens, raised from pure mothers, \$1.00. Tested, \$1.75. I will guarantee satisfaction. Address A. B. JOHNSON, Elizabethtown, Bladen Co., N. C. 10rtdb

Bees Wanted to Fill Empty Hives.

Who will sell first swarms cheapest, ship before June 18th, and guarantee safe arrival? 11ld

J. G. LEHDE, Gardenville, Erie Co., N. Y.

JOB LOT OF WIRE CLOTH AT GREATLY REDUCED PRICES.

Such a brisk demand has sprung up for this, and our customers seem to be so much pleased with the goods, we have succeeded in getting another still larger lot, of one of the largest manufacturers of wire cloth in the world. Please bear in mind that the only way in which we can afford to sell it at the very low price of 1½ cts. per sq. ft. is by selling the entire piece just as it is put up. We have now in stock the following pieces. As fast as it is sold, each piece is crossed out, and the next issue will show what remains.

SOME OF THE USES TO WHICH THIS WIRE CLOTH CAN BE APPLIED.
This wire cloth is first quality in every respect, and is just the thing for covering doors and windows, to keep out flies; for covering bee-hives and cages for shipping bees; making sieves for sifting seeds, etc.
Number of Square Feet contained in each Roll Respectively.

Inches Wide.	No. of Rolls.

JOB LOT OF WIRE CLOTH

AT GREATLY REDUCED PRICES.

Such a brisk demand has sprung up for this, and our customers seem to be so much pleased with the goods, we have succeeded in getting another still larger lot, of one of the largest manufacturers of wire cloth in the world. Please bear in mind that the only way in which we can afford to sell it at the very low price of 1½ cts. per sq. ft. is by selling the entire piece just as it is put up. We have now in stock the following pieces. As fast as it is sold, each piece is crossed out, and the next issue will show what remains.

Inches Wide.	No. of Rolls.	SOME OF THE USES TO WHICH THIS WIRE CLOTH CAN BE APPLIED.	
		This wire cloth is first quality in every respect, and is just the thing for covering doors and windows, to keep out flies; for covering bee-hives and cages for shipping bees; making sieves for sifting seeds, etc.	Number of Square Feet contained in each Roll Respectively.

J. S. TADLOCK,

56fdb LULING, CALDWELL CO., TEXAS.

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they want to dispose of, we will insert notices free of charge, as below. We do this because there is hardly value enough to these queens to pay for buying them up and keeping them in stock; and yet it is oftentimes quite an accommodation to those who can not afford higher-priced ones.

I have a few very fine black queens; price 25 cts. each. **W. P. DAVIS, Goodman, Anson Co., N. C.**

I have a few hybrid queens, which I will take 50c each for. Ready now. **F. C. STEVENS, Moore's Hill, Dearborn Co., Ind.**

I can spare about one dozen hybrid queens at 50c each, and 2 black queens at 25c each. Safe arrival guaranteed. **ELIAS COLE, Ashley, Delaware Co., Ohio.**

I have 25 hybrid queens that I will sell for 50 cts. each. **D. N. MACKAY, Dry Creek, Lan. Co., S. C.**

I have a few choice hybrid queens which I will sell at 50c each. Untested Italians at \$1.00. Safe arrival guaranteed. **G. S. FOX, Mitchellville, Polk Co., Iowa.**

I have 20 hybrid queens one year old. I will take 40 cents each for them. **A. E. KIRKMAN, Maple Cypress, Craven Co., N. C.**

EXCHANGE DEPARTMENT.

Notices will be inserted under this head at one-half our usual rates. All ads intended for this department must not exceed 5 lines, and you must say you want your ad in this department, or we will not be responsible for any error.

WANTED.—To exchange eggs from single and rose comb Brown Leghorns, Plymouth Rocks, Light Brahmas, and Pekin ducks, for warranted Italian queens—any number up to 20 fowls, and as fine as any in the U. S. Write at once.
12-13d JAMES CRAIG, Mt. Meridian, Augusta Co., Va.

WANTED.—To exchange 2 knitting-machines (one Lamb, one Kimbell) bee-hives that have been used some; 50c and \$1.00 apiece, F. O. B., for beeswax, or offers foundation, 44 to 50c per lb., for cash or wax; wax worked on press on shares or for cash.

VIBRATING TELEPHONE.

Patent Applied for.

Gives splendid satisfaction. No exorbitant rental fee to pay—sold outright and guaranteed to work, month on trial, within its compass 2 miles, or more, if desired.

THE COST for private lines IS LESS than TWO MONTHS' RENTAL FEE to the expensive BELL TELEPHONE. THE VIBRATING TELEPHONE is the only PRACTICAL and RELIABLE non-electric Telephone made, and warranted to give satisfaction, or money refunded. Agents can make immense profits erecting lines and get all the work they can do. Territory given Agents in which they are protected. No previous experience required, as illustrated instructions show all about erecting lines. Where I have no agents, Telephones may be ordered direct for private use. Circulars and

H. T. JOHNSON, 102 S Division St., Buffalo, N. Y.

price list free. Mention this paper.

6-17db

HONEY COLUMN.

CITY MARKETS.

ST. LOUIS.—Honey.—Our honey market is very dull. No demand for any kind. Parties prefer strawberries for table use. *Beeswax* continues to gradually decline; hard to sell, and looks as if it would go lower; stock large. Last sales at 24c.

W. T. ANDERSON & CO.,
June 8, 1885. 104 N. Third St., St. Louis, Mo.

CLEVELAND.—Honey.—The market for honey has been very dull the past month, scarcely any thing doing, and stocks on hand standing still; what few sales are made are at former prices, 14c@15 for best 1-lb. sections of white; second quality does not sell. Extracted not wanted. *Beeswax*, 25c@28.

A. C. KENDEL,
June 10, 1885. 115 Ontario St., Cleveland, Ohio.

CHICAGO.—Honey.—There is at present very little demand for honey (this may be owing to cheapness of small fruits of all kinds). Sales are made at 10c@12½ per pound; extracted, 5c@7c. *Beeswax*, 22c@28.

H. A. BURNETT,
June 10, 1885. 161 So. Water St., Chicago, Ill.

NEW YORK.—Honey.—Since our last quotations there is no change in the honey market, still very dull. *Beeswax*, we quote at from 29½@31½c.

May 27, 1885. MCCAUL & HILDRETH BROS.,
34 Hudson Street, corner Duane St., New York.

MILWAUKEE.—Honey.—The honey market is very dull—very little demand for comb honey. In 1-lb. sections, values nominal, 12½@13c. Extracted in pails, 8c. *Beeswax*.—Some demand, 30c@35c. Values easy.

A. V. BISHOP,
May 25, 1885. 142 West Water St., Milwaukee, Wis.

KANSAS CITY.—Honey.—Demand light, and prices weak. We quote choice ½-lb. sections 15c@16c; 1-lb., 13c@14; 2-lb., 10c@11c. Extracted, 5c@7c., according to quality. We need some ½-lb. sections, and shall be pleased to hear from parties having any.

Beeswax, 25c@30c.
June 4, 1885. CLEMONS, CLOON & CO.,
Cor. Fourth & Walnut Sts., Kansas City, Mo.

CINCINNATI.—Honey.—There is no new feature in the market. Arrivals are plentiful, and at low figures, with almost no demand, excepting from our regular customers. Low prices are no inducement. Extracted honey ranges from 4½c@8c on arrival. Prices of comb honey are nominal, with a slow retail trade. *Beeswax*.—We find beeswax in a better retail and jobbing demand than ever, with good arrivals. Prices range from 22c@27c on arrival.

CHAS. F. MUTH,
S. E. Cor. Freeman and Central Avenues,
June 11, 1885. Cincinnati, Ohio.

DETROIT.—Honey.—The market is very dull; a good article is quoted at 10c@11 cents.

June 9, 1885. A. B. WEED,
Detroit, Mich.

PRICE 35 CTS.; BY MAIL, 40 CTS.

A. I. ROOT, MEDINA, OHIO.

EXHIBITION WHITE LEGHORNS BRED BY KNAPP BROS., FABIUS, - NEW YORK.

Our Strain of this Variety Win Highest
Honors Everywhere.

LOOK! At MADISON SQUARE GARDEN, New York City, where the largest and grandest exhibition of poultry to be seen in America is annually held, our birds won in 1884, 1st, 2d and 3d Prizes on Breeding-Pens, 2d on Chicks, the Specials and Silver Cup for Best display; at State and County Fairs every first prize offered. Again in February, 1885, at the great New York Show, our birds were awarded FIRST PREMIUM MERIT on ALL entries, including Club's Special First Prize for Best Pair Chicks, for Best Breeding-Pen (averaging 95½, highest score 98), and the \$20 Special offered for Largest and Best Display in Leghorn Class, Brown or White, with 28 breeding-pens and 38 pairs in competition.

No better laying variety exists; all acknowledge this. Send and get the best breeding stock to be gotten in the world.

EGGS FOR HATCHING from our Prize-Winners, carefully packed in baskets, \$3 per 13, \$5 per 26. All orders will receive our personal attention and will give all good satisfaction.

This will not appear again. Send stamp for our 1885 circular giving further particulars, and price of fine chicks after Sept. 1. Box 74. 12d

Queens.

If you are in a hurry for them, give me an order; 25 laying now; 90c each; tested, \$1.50; fine stock. Can send by return mail in my improved Peet cage.

L. HEINE,
12d Bellmore, Queens Co., N. Y.

BEEES FOR SALE.

2, 3, or 4 Frame Nuclei, \$1.00 Each;
Untested Queens, \$1.00;
Full Colony on L. Frame, \$10.00.
Address RICHARD EDMUNDS,
12-16db BOX 222. GRAND CROSSING, COOK CO., ILL.

FOR SALE.

I want to sell 100 L. frames of comb, 9¼x17½, over one-half worker-comb. \$15.00 will buy them.
1111db J. W. BRADLEY, COLUMBIA, BOONE CO., MO.

Vol. XIII.

JUNE 15, 1885.

No. 12.

TERMS: \$1.00 PER ANNUM, IN ADVANCE; 2 Copies for \$1.90; 3 for \$2.75; 5 for \$4.00; 10 or more, 75 cts. each. Single Number, 10 cts. Additions to clubs may be made at club rates. Above are all to be sent to ONE POSTOFFICE.

Established in 1873.

PUBLISHED SEMI-MONTHLY BY

A. I. ROOT, MEDINA, OHIO.

Clubs to different postoffices, NOT LESS than 90 cts. each. Sent postpaid, in the U. S. and Canadas. To all other countries of the Universal Postal Union, 18c. per year extra. To all countries NOT of the U. P. U., 42c. per year extra.

AN INCREASE OF COLONIES TO PRESERVE COMBS.

A SUBJECT OF VERY GREAT IMPORTANCE INDEED TO MANY OF THE BEE-KEEPERS.

AFTER the great mortality of bees the past winter and spring, the question comes from almost every quarter, "What shall I do to preserve the combs, and how can I increase the few remaining colonies so they will again take all the combs?" As I propose to answer the first question by telling how to do the latter, I will dwell on the first only long enough to say, that if your bees are so reduced that they can not possibly be multiplied so as to use all the combs left by those which have died, the only thing to do is to fumigate them with burning sulphur every two or three weeks during warm weather, unless you have some moth-proof room in which you can place them, after fumigating them thoroughly twice, which should have two or three weeks intervening between the times, so as to allow all eggs to hatch. The hanging of combs two or more inches apart can not be depended upon, as I have had quite a number of combs destroyed in trying that plan.

The main question before us, then, is, how to increase the few remaining colonies as much and as early as possible. As nothing can be gained by trying to increase colonies till some of them have their hives full of bees and brood, I advise all to wait until at least *one* is strong, before trying my plan. When you have such a colony, and desire to proceed, turn to page 304 of GLEANINGS for May 1, and read carefully the plan I there give for forming a nucleus; for this is the system we are to adopt.

Besides the strong colony, it will be necessary to

have one other fair colony; and if any do not have such a one, I should advise the purchase of one, or a pound of bees with a queen. Having two colonies, such as is referred to, I proceed to the strongest and get in my box (as given on page 304) about a pint of bees, which in due time have given to them the queen from the weaker colony, when the bees and queen are left in the box until the next morning, and hived as I gave directions, taking the comb of brood from the weaker, and the frame of honey from the stronger, that are placed in the hive upon hiving them. The colony from which you took the queen is now allowed to build queen-cells; or you can use the Alley or other improved plans of getting queen-cells, whichever you prefer.

As soon as the first cell is sealed, you are to form another little colony, using the same queen as before to form it with; when in 48 hours I give the first cell which was sealed to the little colony the queen was removed from.

About this time I also make the third little colony, using bees each time from the strong one, and the same queen to form each colony with. In 48 hours I give a cell to the second little colony, and thus keep on forming colonies as long as I have cells or virgin queens to give them; for if the cells are not all used up when it is time for the first young queen to hatch, I cut all out but one (which should be left for that colony), and place them in a queen-nursery, so that I can use virgin queens instead of cells. If I was successful in getting a good lot of queen-cells, I have, at the time the last virgin queen is used, from ten to twelve colonies of bees, into which I now begin to place the combs I wish to keep the moths from. I forgot to say, that, after making the first little colony, I placed a comb in the

strong colony in place of the frame of honey taken from it; and that for each succeeding colony formed, this comb now having a few eggs in it, is taken out and another put in its place, while the frame of honey should be taken from those you wish to preserve from the moth. In putting the frames of combs in the little colonies I place them beyond the division-board until the queen gets to laying, when one by one they are placed in the brood-nest, as the colony gets strong enough so the queen will fill them with eggs.

The bees will care for the combs as regards keeping the moths from them, just as well beyond the division-board as they would if no division-board were there. When the last little colony is made I use nearly three times the bees in making it, and give, when hiving them, two or more frames of hatching brood, so that, in a week or so, I may again have a fair colony to rear queen-cells from; for at the expiration of about two weeks the same operation is to be repeated, and eight to ten more colonies formed.

Again in two or three weeks, or as soon as the original strong colony is in fine condition, more are formed; but as it grows later in the season, a quart or more of bees are taken to form the colony, instead of a pint. Finally, as fall draws on, the first-formed little colonies are strong enough to spare bees. At this time I take bees from three or four colonies, thereby getting bees enough to make a good full colony at once. By the above plan it is no trouble at all to build up a depopulated apiary again, especially if you are willing to feed liberally when honey is not coming in from the field; and I believe it is far cheaper than to buy bees by the pound, and queens to put with them, as many do.

G. M. DOOLITTLE.

Borodino, N. Y., June 1, 1885.

Friend D., I especially approve of your plan of getting at least one strong colony, before you begin forming nuclei. A powerful colony will bear drawing bees and brood from to a wonderful degree, without material injury; but we should be careful how we cripple colonies already weak, by untimely division or abstraction. Circumstances may make it needful to modify any rules that may be laid down; but I think any smart bee-keeper will be able to devise ways similar to the one you mention, to get his surplus combs under the control of the bees, even if he have but very few colonies to start with.

AN IMPROVEMENT IN REGARD TO MAKING FOUR-PIECE SECTIONS.

HOW TO DO SMOOTHER WORK WITH AN ORDINARY CIRCULAR SAW THAN CAN BE DONE BY THE AID OF THE SANDPAPERING MACHINE OR PLANER.

HOW slow is the march of progress! Hundreds of times I have invented cumbersome machinery for doing certain kinds of work, that I thought at the time were marvels of skill and ingenuity, and then found out some time afterward that the whole machine could be dispensed with entirely, and still do better work, and faster. I have seen this so many times, that, when something new had to be worked out, I have thought to myself, "Now

very likely when we get more acquainted with this business, *this* whole machine will be dispensed with entirely." For all that, the machine has to be built. The same thing is true the world over. Sitting down and waiting will not get us along any. We must roll up our sleeves, and push into the business before us; hew out something that will do the work, change it, simplify it as we go along, and when we get it to produce exactly the thing we want, then, but not before, we can begin substituting simple means for what before has been complicated.

Three months ago we printed a cut of a machine for making section boxes out of four pieces of wood. The machine has been running in our saw-room ever since it was gotten up, and has worked up short bits of basswood into enough nice sections to pay for itself several times over. The machine I allude to has a circular saw and sandpapering wheel together, as shown on page 158. Now hear the sequel:

To-day Mr. Gray brought me some pieces of wood sawed up for ends of wide frames. These wide frames are to hold only one tier of sections, so the pieces are only four or five inches long. They are too short to run through the planer practicably. We have formerly sawed them with a planer saw; but such a saw is too slow, as you all know. Well, these pieces were sawed with an ordinary ten-inch circular saw, and they were smoother on both sides than the work of the planer saw, or the planer or sandpapering machine.

What did they do it with? Why, they did it with an ordinary ten-inch saw, *filed without any set*. It is possible to use such a saw without any set, because the stuff is so short, and because the basswood was so thoroughly seasoned. To accomplish this, however, several things are necessary. First, as I have said before, use extra nice basswood lumber thoroughly seasoned. Second, a filer who can file a saw so it can be run safely without any set; that is, on short stuff, such as I have mentioned. Third, a mandrel that runs absolutely true. Every tooth of your saw must follow in an exact line the tooth that goes before it. Fourth, a man long accustomed to the business, for a sawyer.

After the saw had cut up a large pile of these sticks, it was put on to four-piece sections, both of basswood and white poplar, and it turned out the best work that has ever been made in our establishment. I asked our saw-filer if he could file another saw just like that; that is, so it could be run without set, and without a single tooth in the saw leaving a mark on the woodwork. He said he thought he could, and he is now at it.

I have given you this long description of the matter, because I think there are expert saw-filers and sawyers among our readers who can do this same thing. All you want in order to make beautiful sections, and make them rapidly, is a gang of saws to do the dovetailing, and a single rip saw to slice up the blocks.

Now, then, friends, to do this you must have perfect tools, and you must be expert

in their use, or it can not be done at all; but when you do reach the proficiency to be able to do it, you can do it faster than you can make the ungainly things that a good many of us have used and called sections. Perhaps I might add, that, in filing the saw the teeth are to be filed almost exactly straight across; but the filer first files every other tooth, then turns the saw over and files the remaining teeth. You will need to take a new saw that has never had the teeth set at all. Our ten-inch rip saws are just about the proper gauge; and when they come from the factory without injury or bruise, they are perfectly flat. May be your mandrel will have to be trued up before you can do it; but it will pay well to have a mandrel and saws kept in just this trim.

Since the above was written, our saw-filer has filed another saw, so as to do as well as the first; and we are not only using it on four-piece sections, but also on the one-piece, making, I think, finer sections than we ever made before, without the use of a planer at all. It takes an expert man at the saw-table, however. A new man would be pretty apt to get the sections thin at one end, or, worse still, get them to bowing. But I feel sure that almost any man who runs a circular saw can, by steady practice, learn to cut sections in the way I have mentioned. It is a great saving of lumber, saving of time, and a saving of expensive machinery. Another thing, a good many sections are spoiled by being put through the planer. All this loss will be saved. The man who files the saw must also be an expert; but I believe the friends who own saws can manage it if they try hard.

SHALL A BEE-JOURNAL BE CONNECTED WITH THE SUPPLY BUSINESS?

THE OPINION OF A CORRESPONDENT OF THE C. B. J.

WE extract the following from the *Canadian Bee-Journal* of June 3:

I think it is very fortunate that its editor [D. A. Jones] is in the supply business, as I maintain that we are benefited by this. GLEANINGS is a good example of this. I say that GLEANINGS is worth more than any other journal to-day to any American bee-keeper, if for no other reason than such articles as are useful to bee-keepers are continually being brought to their notice. It is all nonsense about a bee-journal being better, apart from a supply business. Its editor is thereby enabled to give better value for the price. In answer to the question of A. I. Root, when in a short editorial giving the reduction in glass, he says: "Now it seems to me, friends, it is a pretty good idea to have a bee-journal that is able to tell you twice a month all about the decline in price of such things as keepers are obliged to buy more or less. Don't you think so?" I reply, most decidedly. To persons living in Canada there is not so much advantage, but I have often thought that the bee-keepers of the United States should be very grateful to A. I. Root for what he has done and is doing in this way. I might say that every article I have purchased from him has been well worth the price charged. Of course, having to pay a heavy duty on some lines of goods is against us. Now I look upon the C. B. J. as I look upon GLEANINGS, that your position enables you to take the same place in Canada that A. I. Root does in the States, and I am indeed grateful that you have undertaken its publication.

We thank friend Deadman for his kind words; but I would suggest that, by

way of variety, we have one or more bee-journals not connected with the supply business; that is, providing there is sufficient demand for such a journal. No doubt there would be some advantages in having such a journal. But now may I be permitted to make a little protest of my own? When new bee-journals start up (and doubtless they will start, as they have started), will they please to bear in mind that it is neither courtesy nor policy to commence pecking at old established journals? Suppose you should attend an evening party, and you should commence right out, before all those people, abusing some one who is present. What would be thought of you, if you persisted in dragging your personal likes and dislikes into the presence of a well-bred company? You would probably be severely let alone, and you might possibly be shown the door, in some circles. Well, whatever appears in a public journal is, in one sense, before the people, and in a place where everybody is bound by all rules of etiquette to behave himself as becomes a gentleman. I have sometimes thought that the opinion seems to have obtained a lodging in some hearts, that a man might build himself or his journal up, by saying sneering and insulting things of those who had acquired at least a tolerably fair standing by years of at least tolerably fair service.

MORE SWINDLING NOTICES IN REGARD TO ADULTERATING HONEY.

ALSO SOMETHING ABOUT NEWSPAPER EDITORS THAT PERSIST IN PUBLISHING THESE FALSEHOODS.

WE clip the following from the *A. B. J.*: MISREPRESENTATIONS ABOUT HONEY.—Mr. A. F. Robson, Italy, N. Y., writes thus: I clip the following from the *Yates (N. Y.) County Chronicle*, and send it to the *Bee Journal* as a specimen of lying: "The Albany correspondent of the *Tribune* says: 'Some curious facts were revealed by the packers of canned goods in private conversation. You would not think the parings and cores of apples of any use, would you?' said one of the packers to a friend. He then continued: 'Well, a fruit-packing establishment makes use of every thing; like the pork-packing factories, which save every thing except the pig's grunt. When we are packing and drying apples, we have tons and tons of parings and cores. These we sell to the makers of jelly. All kinds of jellies are made of the material. You can not buy real currant jelly in the groceries. Every bit of it is soaked with some essence in it. But that is not the sole use of apple-parings. Occasionally we keep them so long that they can not be converted into jelly.' Then we sell them to the makers of strained honey. All the strained honey that you see in the market is made of it—there is not a bit of honey about it." What next? Does there not seem to be a demand for this kind of lies?

And so all this liquid honey to be found in the markets is made from apple-parings. is it? The above extract does not state clearly whether the statement was published in the *N. Y. Tribune* or not; but I should like to know for certain whether any of our readers have seen the above in the *New York Tribune*, or in any other newspaper. Well, instead of sitting down and folding our hands, and saying there is no help for it, we propose one means of helping the matter as follows: Keep a standing notice in the col-

umns of our bee-journals, of the names of newspapers that persist in giving place to these falsehoods. Hunt up the name of the reporter, if it is possible to get it, and give him all the publicity he wants. When the editor of any newspaper will correct the statement, and apologize for letting it go into his columns, then we will take his name out, and not before. If the bee-keepers of the world are not a very large body, they are at least large enough to let their influence be felt. Who is the reporter that furnished the above, and what paper besides the *Yates Co. Chronicle* has given place to it? I think we will fix it about this way: We will start a new department in GLEANINGS, with a head something like the following:

FALSE STATEMENTS IN REGARD TO THE HONEY BUSINESS OF OUR COUNTRY.

As a protection to our bee-keeping population, we propose in this department to publish the names of newspapers that persist in publishing false statements in regard to the purity of honey which we as beekeepers put on the market. When any paper will correct the matter publicly, with suitable apology, the name will be dropped. A copy of this article will be mailed to the editor of any paper giving place to such statements, with a written protest, before the name of the paper is given. After the lapse of a suitable time, if the matter is not corrected we will keep a standing notice, to warn the people at large that said paper does not scruple to give publicity to this class of falsehoods.

The more one reads the extract above, the more diabolical it sounds. Please notice: "After the apple-parings have been kept so long that they are spoiled, and won't make jelly, they are sold to the makers of *strained honey*." Furthermore, "All strained honey in the market" (I presume they mean liquid honey) "is made of" these same sour appleskins. Of course, this includes packages put up by the apiarists themselves; and we are told, with a great show of candor, there is not a bit of honey about it.

GLEANINGS AS AN ADVERTISING MEDIUM.

SOMETHING ABOUT PUTTING NEW GOODS IN OUR PRICE LIST BEFORE THEY HAVE BEEN PROVEN, ETC.

I WISH to say of GLEANINGS, that it is almost too good for advertising purposes. I inserted an advt., got answers from almost everybody, and as many orders as I could fill.

Bees are all in fine condition, and I did not lose any in wintering. I took my first comb honey May 15, which I think is very good for this locality. In the fall my bees bring in a quantity of beautiful dark-red honey, which is very thick, and has an excellent flavor. Can you tell me what it is made of?

Do you sell any reversing devices at the present time? I can not tell from GLEANINGS whether you do or not.

EDWARD S. LEA.

Brighton, Md., May 27, 1885.

Friend L., GLEANINGS is an excellent advertising medium for seasonable goods where the prices are reasonable or low; but some of the brethren have complained that they did not get a single application from their advertisement. The reason was, the advertisement was something not quite in our line, the price was high, or it was something behind the times, and not wanted by any-

body. As an illustration, one friend advertised some books on freemasonry. Nobody ever replied to his advertisement. Another advertised seed wheat. The price was rather high, and the kind of wheat was something the people did not know much about. I believe he had no answer. But as a rule, those who have advertised *bees* at low prices have been, like yourself, more than satisfied.—I can not give even a guess where the red honey came from, without tasting it. When you get some more, if you will let us know I will send you a wooden block in which to mail us a small portion.—We are selling the reversing device described and illustrated on page 157. We are selling a great many, and are waiting anxiously for reports from them. They are not yet in the price list, because I do not wish to put any thing in the price list until it has been pretty well tested by actual use, and at least a good many different people have decided that it is worthy of a place among the established "bee-fixings." The Heddon honey-board, Moore's crate for sections, Klimitz' queen-catcher, and quite a lot of other things are at present undergoing the ordeal of public opinion. If they decide them to be good during the present season, they will go into the price list.

NOTES AND QUERIES.

FIGHTING AND DEAD BEES IN FRONT OF A NEW SWARM.

I HAD a colony that cast a swarm on the 24th. It was an extra large swarm. They settled on a fence-rail. I hived them in the usual way, and ever since then they have been fighting. The ground around is covered with dead bees. The entrances are three feet apart—hives all alike, and painted white. What is the matter?

Hunter's Depot, Ky., May, 1885. R. B. BARNES.

[Friend B., your concluding words give the clue to the whole trouble. Three feet is not far enough apart to place hives; and if the hives are painted all alike, the trouble is likely to be still worse. They have probably got over their quarreling, and are all right by this time; but many bees will get into the wrong hives, and be lost, if you leave them as they are. If you face one about so as to point a different way, this would make some difference. Better put them as much as eight or ten feet apart, if you can conveniently.]

DOES THE SWARMING TELEPHONE INJURE BEES?

I am ashamed to ask any more questions, but can not listen any longer to that new telephone shooting my bees once a minute, without asking you if you think it brings one down at every stroke.

Sheboygan Falls, Wis., May 26. QUANDARY.

[Friend Q., the same thought came into my mind when we first used the swarming telephone; but upon going out and watching the bees as they bumped against the wire, I was satisfied that it did not hurt them materially; for after being knocked out of their course a little they flew along as if nothing had happened. Will some of the other friends make observations, and report? Bees often bump against blades of grass or stalks of timothy; but even if it knocks them down it does not seem to hurt them any. I would not have the wire so near the bees that they would strike it very much while at their regular work. If you can conveniently, raise it so high that a bee seldom strikes it unless the swarm is in the air]

HOME-MADE CANS FOR HONEY.

THE WAY OUR FRIEND MUTH-RASMUSSEN DOES IT.

AS shipping honey-cans made up is very expensive, on account of the bulk, we have for some time been doing quite a little trade with the friends away off, by sending them Jones cans in the flat. We extract the following article from the *Pacific Rural Press* of March 28, written by our friend Wm. Muth-Rasmussen:

The Jones honey-cans can be procured in the flat, most of them at one-half the cost of ready-made cans. Fifty of the sheets, forming the side of the cans, are stuck inside each other, making an almost solid block, little larger than a single can. Thus they take up very little room in shipping, and the freight charges are consequently considerably less than for ready-made cans. The bee-keeper may, at his leisure, put these cans together and keep them on hand for filling directly from the tank. Larger cans may of course be used for home storage, and the honey from them can be poured into a tank at any time, when it is desirable to fill a lot of the small cans. The only extra implement required is an

"EXPANSION TOOL."

Which consists of a center-piece with handle, to which are loosely riveted four pairs of U-shaped springs, holding four plates, or leaves. These leaves drop together when the handle is raised, but spread apart when the tool is set down on a flat, smooth surface. After putting the top, bottom, and side of a can together, the expansion tool is dropped through the hole in the top. By pressing on the handle, the center-piece is pushed to the bottom, and the four leaves, by the tension of the springs, are forced outward, pressing the edges of the sheet firmly against the flanges of the top and bottom. All the joints are now soldered in the usual manner, and the expansion tool removed by simply pulling the handle, which releases the tension on the springs and causes the leaves to drop close together. The cans are then tested by filling them with water and letting them stand a little while. If any of them leak it will be shown by the water, and it is far easier to mend the leak now than after the can has been filled with honey, as every old bee-keeper knows. In

FILLING THE CANS

They should be placed on a scale which will take off the tare, directly under the honey-gate of the tank; and if the honey is not too cold and thick, it will keep a person busy opening and closing the gate, removing and covering the filled cans and putting empty ones in their place. Previous to filling the cans, each cover should have a small pin-hole punched in the center by a sharp-pointed prick-punch. This is for letting out the air, when sealing the can.

SEALING.

I make my sealing-wax of equal parts of rosin and beeswax. Dark-colored beeswax answers the purpose just as well as light, as the rosin makes the mixture of a bright, yellow color. The wax and rosin are melted together in a can on the stove, and

a little at the time poured into another can, provided with a handle and lip, from which it is poured into the groove around the cover of the honey-can. As the air in the can gets warm, and expands under the influence of the hot sealing-wax, it would force its way out and make air-bubbles in this, if the cover were not provided with the above-mentioned air-hole. When the sealing-wax has cooled off, the air-hole is closed with a small drop of solder.

Finally the labels are put on with dextrine or paste, and the cans placed on shelves, or packed in boxes for shipment. The boxes should be marked with the size and number of the cans, and with the name and address of the producer, which can be done by means of stencil-plates, so that nothing remains to be done, before shipping, but to add the name and address of the consignee. If the honey is still liquid at the time of shipping, it will be necessary to mark the box "This Side Up." But if the honey is granulated in the cans, they will stand any amount of rough handling. To prevent the labels from injury by rubbing against each other, the cans should be tightly wedged together by wads of old newspapers; and if there are two or more tiers of cans in a box, a sheet of clean packing-paper should be placed between them.

THE SIZE OF CANS

Must depend partly on the public demand, partly on the price of the honey and of the cans. To avoid trouble in making change, it will be best to adopt such sizes as can be retailed at even 25, 50, or 75 cts. each. People seldom care to buy a larger quantity at the time, and generally have the cash ready which they wish to expend.

It is wonderful how readily, particularly the smaller cans, go off. At a recent "Indian fandango" in this neighborhood I sold in a couple of days 50 two-pound cans at 25 cents each. Old and young of the dusky tribe came with their two bits, and wanted a can of honey, and many were no doubt influenced by the knowledge that the can could be used again, when the honey was gone.

WM. MUTH-RASMUSSEN.

Independence, Cal., Feb. 1, 1885.

SHIPPING BEES WITHOUT WATER.

ALSO SOMETHING ABOUT SIMPLICITY HIVE-BODIES WITHOUT COVERS.

HOW do you fill those tin bottles with water in your bee shipping-cages? Why do you not sell Simplicity bee-hives without cover or bottoms? You can sell bodies with rim-pieces, or bodies without rim-pieces. You know the Simplicity bodies are used also largely for storing surplus combs away; and if we need them we can get a cheap bottom-board, and also a cheap cover by your tin sheets. A good many bee-keepers have use for a large number of bodies, but not for cover and bottom; we use, sometimes, these hives three stories high. What is the use, then, of the three covers, or bottom? If I were a supply-dealer I am sure I could sell a large number of these hive-bodies, and could do the bee-keepers a great favor.

H. M. MOYER.

Hill Church, Berks Co., Pa., May 30, 1885.

Friend M., we do not use tin bottles any more at all. We have not used any for two years. By many experiments we have satisfied ourselves that, while sometimes during an exceedingly dry spell a shipment is lost for want of water, there are more times when the water does more harm than good, with the best arrangements we have been able to get up. You can fill the bottles, however, by means of a common oil-can filled with water, or by holding them under a stream of water, falling say a foot or two. —In regard to the Simplicity bodies, why, bless your heart, we have been selling them for ten or fifteen years in just the way you

mention. If you examine any of our price lists for years past, you will find that it says the price of a body only is equal to the price of a cover; so that, in any of our tables, bodies will be half as much as a one-story hive with one cover.

A WOMAN'S EXPERIENCE IN COMMENCING TO KEEP BEES.

SOME OF HER PERPLEXITIES AS WELL AS SUCCESSSES.

I HAVE always thought I should like to take care of bees. We have been in the habit of buying honey of our neighbors every fall, and it seemed to me I would rather pay out money for bees, and raise my own honey. So about the middle of June last year I purchased a swarm of Italians, for which I paid \$9.00.

We live in the midst of a farming country, with plenty of fruit-blossoms, clover, and buckwheat, and near the shore of beautiful lake Chautauqua. I sent for the A B C book, and, not long after, for GLEANINGS. The more I learned about bees, the more I found there was to learn. I so much wished I could visit some good apiarist, and ask, oh so many questions! but there were none within 20 miles, and so I turned again and again to the A B C book.

My neighbors keep black bees, but they simply hive them when they swarm, and take up honey in the fall. If they half die through the winter, it is no more than they expected. I found I could not gain very much information from them, so I resolved to depend on what I could learn by reading, and my own common sense. Experience is often a dear teacher, but a pretty good one after all.

When I bought my bees, the brood-combs were nearly empty. They went right to work, however, and soon filled the brood-combs, but did not seem at all inclined to work in the sections. About the last of July they sent out a nice large swarm. Perhaps my experience in regard to the swarm may teach others who are just beginning, to be more watchful.

I am a farmer's wife, and do my own work. Previous to their swarming I had watched them pretty closely for two weeks. That day I had been unusually busy, and an occasional glance toward the hives was all the attention I gave them until about 6 P. M., when I went out to the hive. An air of listless inactivity about the front of the hive made my heart jump. I lifted the cover; about half the usual quantity of bees were dejectedly crawling around the combs, as though they had lost their best friend. My bees, my beautiful yellow bees, with the Italian queen, were gone! I went into the house and sat down. I was very tired, and this disappointment made me feel as though a good old-fashioned cry would be the next thing on the programme. My husband came in for the milk-pails. He had been very skeptical in regard to my ability to take care of the bees.

"What is the matter?"

"My bees are gone."

"Are you sure?"

"Yes."

"Let's go out and see; may be they are somewhere round on the trees."

"Oh, no! they must have swarmed this forenoon, and now it is almost night. They have gone to the woods long ago."

But he went out, and soon came back, saying, "They are on a low branch of an apple-tree, just back of the hen-house."

Then I jumped. I seized a sheet, and spread it in front of a hive already prepared. He sawed off the limb, and I shook them gently in front of the hive. Didn't I enjoy seeing those bees go on?

Well, they went to work upon their foundation, and built combs and filled with honey and brood. The other hive did not do much for a long time, then their queen began to lay, and she proved a hybrid. Soon cold weather came. I fed them sugar syrup a little in October. The last day of October I put them up snugly in chaff hives. Whenever there came a day warm enough, I would peek in to see if they were all right. I believe we had only one day in March when the mercury went above freezing. That day I looked in, found them all right, and could see they had some honey, but did not like to disturb them enough to see how much, and so for fear they might be getting out I tucked some candy in under the burlap across the frames. Then came day after day of zero weather and very little snow. I would go out and bank up the lower part of the hives with snow, and throw some lightly over the entrance.

At last spring came, and my two swarms came through, strong and well. My neighbors were complaining of heavy losses. One day in April I was alarmed by signs of dysentery around my Italian hive. I think they had found a heap of rotten pomace near a cider-mill not far off. I fed them some sugar syrup to coax them to stay at home, and in two or three days all signs of disease disappeared. I do not know whether that was the right thing to do or not.

I did not take off the chaff cushions till about the middle of May. On the 23d of May the Italian hive swarmed (this time I was watching), but they did not cluster, and soon went back into the hive.

The next day was rainy. On the 25th they came out again, and again went into the hive. Reading in the A B C book that bees would kill their queen if she did not swarm with them, I looked into the hive soon after they went back, to see if there was any trouble. The bees had gnawed through the burlap, and I found the queen and a few bees on top of the burlap. I thought I would cage her, and when they came out again put a new hive in the place of the old, and let her go in with them when they went back, or else I would divide the bees and give her part. I got my cage all ready; but I disliked to pick her up by her wings, lest she might be injured; so I let her crawl on to a feather, and two or three of the bees with her. I put them into the cage, as I supposed, and looked to see if she was there. The worker-bees were there, but she was not. I did not see her fly, I did not see her drop. Now, where was she? I looked long and carefully in the grass—no queen. Did she fly? and if so, would she find her way to the hive, or be lost? At night I looked the hive over carefully, but could find no queen. Did she fly and get lost, or make her way back to the hive, and the bees kill her?

I do not like hybrids. I always get stung when looking over that hive. They are doing good work, though, and the side sections are nearly full of nice honey.

I do not want my hybrid hive to swarm naturally, so now I send to you for two queens. I am out of pocket about \$25.00 for bees, hives, foundation,

queens, etc., and as yet have taken no honey, and received no income. I am not ready, however, to go into the column of Blasted Hopes. Indeed, I am quite confident I shall make a success of it in the end.

SARAH M. W. BENTLEY.

Fluvanna, N. Y., May 28, 1885.

My friend, I have had bees behave just as yours do, when the queen was clipped. Are you sure she is not a clipped queen? I am inclined to think she is in the hive all right; if not, you will find queen-cells within 24 or 48 hours. You could have divided the colony without any trouble, without purchasing any queens; but you will probably get along faster with a fertile queen in each part of the divided hive. If I were you I would be careful about paying out any more money until you get some in. Your husband and the other good people can be much quicker convinced of the possibilities with bees by seeing you market a good crop of honey, than by any thing you can possibly say to them. I can imagine just exactly how you felt, when your bees had swarmed, and you did not discover it until 6 o'clock in the afternoon; and I can tell something how your spirits arose when your husband announced that they were hanging on an apple-tree back of the poultry-house.

BEEES AND CIDER-MILLS.

HAS A BEE-KEEPER ANY CHANCE OF REDRESS BY LAW?

WE clip the following from the *Kansas Bee-keeper*. It is a portion of an answer given by our friend J. E. Pond to one of our bee-friends who claims he has lost bees to the value of \$1000 because of a cider-mill run by his neighbor:

A cider-mill would not be beneficial to an apiary, if near enough to it so that the bees could get to it. It might be beneficial to others, though, and probably would be to its owner.

A bee-keeper can not maintain an action against the owner of a cider-mill, erected on his own land. As to the question of damage, the cider-mill man might say the bees were a nuisance and damage to him. A man has a right to erect any thing on his land that is not an injury to his neighbors; that is to say, in the form of a nuisance. A cider-mill would not be considered a nuisance, and the courts would say that the bees must be shut up. I am aware that a cider-mill is rough on bees, but there is no help for it in law. The cases Mr. B. mentions are not parallel. A hog-pen is a nuisance, on account of the smell, and detrimental to health. The flooding of land by a dam is not at all parallel either, for there is a direct act done which causes damage. In the above I have given the legal status of the matter. Morally, my idea is much the same. I don't see why my neighbor should be kept from putting up a cider-mill on account of my bees. My course, if he should do so, would be to go to him and get him to allow me to put netting over the windows, or else try to get him to run his mill nights, and by force of moral suasion endeavor to get him to work as easy on the bees as he could. The matter of notice amounts to nothing. The only way an action could be maintained at law would be on the ground that the cider-mill man willfully and maliciously destroyed bees when he need not do so.

I want to emphasize the suggestion friend Pond makes, of getting wire netting to put over the doors and windows of cider-mills. I wonder if lawyers always give that same sort of advice to their clients. Christian lawyers most assuredly do. Please notice, that our bee-friend says he has lost over a thousand

dollars. Very likely the cider-mill man has been annoyed to a considerable extent, if he is not out of pocket more or less. Of course, he did not kill a thousand dollars' worth of bees, but the bee-man thinks he killed so many that his colonies could not winter over. We will suppose the cider-mill was \$100 damage instead of \$1000; now, it is not likely it would have required over \$10.00 outlay to have fixed that cider-mill so that a bee could not get a sip of cider. The wire netting would very likely be a considerable benefit to the mill-owner as well as the bee-owner; and it would certainly be a very bad neighbor who would not cheerfully assent to a proposition such as friend Pond suggests. Oh how easy just a little of the spirit of brotherly love would fix all these differences!

FRIEND PORTER'S COMMENTS ON BLANTON'S APIARY.

ADULTERATION OF SUGAR, ETC.

YOUR illustration of friend Blanton's apiary ought to be very suggestive to many. On "stilts" you may call it; but the ease with which a tall man can work among hives elevated one and a half feet from the ground, and with a flat roof, so that each hive is a table, ought to be apparent, if it is not. Years ago I adopted short posts well set with cross cleats on top to support my hives, and I could not be tempted now to go on to the ground again.

My covers are all 18½ x 26½ inches, and one of the most valuable improvements I ever made was to cover each with a sheet of tin, and paint it. Roofing tin 20 x 28 is the kind. Wood covers will not stand in this climate, let them be selected never so well, and painted. No more leaky covers and wet cushions and quilts below them. This for good Mrs. Axtell, whose losses will be regretted by many a reader of her great report for 1883.

Now, what can be handier than to have tables on each side? Opening a hive we place the upper story on one, and it is ready to receive the combs taken out, and can be made bee-tight by throwing a sheet over it—an important matter when bees are disposed to rob.

We always winter on summer stands here, and bees fly quite freely every pleasant winter's day. A burlap bag of chaff above the duck quilt affords such protection that no losses need be feared, provided the bees are really in a vital condition, with supplies of honey, a good queen, with young bees.

Robbing, following careless exposure or queenlessness, is a cause of more loss than any other one thing here.

Now a word in regard to the sugar-feeding. I should like to ask the experimenters, pro and con, and especially friend Doolittle, for his last letter calls this matter up, of what value are such experiments, if we are not to know what kind of sugar is fed? We are most of us delightfully ignorant of what we get now in buying "standard granulated sugar." I have been informed on good authority that all of our refined sugars are adulterated with grape sugar, or, rather, that they can be, and to a great extent are. Perhaps the low price of sugar, and the high price of corn, makes it less profitable now than formerly. If made free from chemical impurity, it may not poison, as glucose has, but it

is not sweet enough to take the place of good nectar. The point is, with this uncertainty as to its character, how can any such experiments be of definite value as bearing upon "the pollen theory"? Here we are at times greatly annoyed by the accumulations of pollen in the brood-combs. They appear to use a great quantity of it, and often clean out combs, I notice.

Our season has been very backward, and for four weeks prior to the 22d we had only one light rain. Virginia will not, it is thought, produce more than one-third of a crop of wheat, and about the same of hay and oats in consequence. Fruit-bloom was abundant, and the yellow-locust bloom was wonderfully profuse, and it has supplied an unusual amount of nice honey. A hive on the scales gained an average of 5 lbs. daily, and I have sections already capped; 90 colonies, and not a weak one among them. Ten were lost by starvation and robbing in wintering.

Now as to the markets, never before have prices been so low, and markets so dull. As producers we must be prepared to bear our share of the results of the general stagnation. While we have to sell cheap, we can buy low. It were useless to fold our hands and cease endeavor. There are no hard times when all that we need is so abundant. How different would it be if famine or pestilence should visit our fair land! Surely we can not expect to get 20 and 25 cents per pound for honey, when refined sugar is sold at 6 and 7c per lb. J. W. PORTER.

Charlottesville, Va., May 25, 1885.

Friend Porter, excuse me for objecting to any thing from so good an authority as yourself; but no one has as yet given satisfactory proof that granulated sugar can be adulterated, although it has been talked about at different times for years past. The cheap grades of brown sugar may be adulterated by grape sugar, and perhaps to some extent coffee A may also be adulterated; but granulated sugar is composed of dry hard crystals, and grape sugar can not be made to form crystals. If there is any thing that can be used to adulterate granulated sugar without detection, I have never heard of it. Is not this matter of adulteration of granulated sugar off from the same piece as the adulteration of comb honey?

PREVENTING AFTER-SWARMS.

HEDDON'S METHOD OF DOING IT.

WILL you please tell us, in GLEANINGS or otherwise, what is the Heddon method of preventing after-swarms, which we often see mentioned? ENQUIRER.

FRIEND HEDDON'S REPLY.

About eight days after a colony casts a prime swarm, the queen-cells, that were left behind to re-queen the old colony, begin to hatch. The first queen out instinctively scents danger from rival queens that will soon hatch from the other queen-cells; so she at once attempts to destroy her rivals by stinging them before they come out for even battle. The bees seem to dislike this act of depravity; and to postpone bloodshed they divide up, a part coming out with this queen (sometimes two or more queens) while the rest remain to await the hatching of the other cells. Thus we get after-

swarms. They seem to be Jack-at-a-pinch swarms, and not the fulfillment of natural desires, as are prime swarms.

Many times several of these after-swarms are cast, and it often seems that they never would cease as long as the queen-cells hold out, and the old colony could furnish workers to make up these little swarms. We have been advised to stop this after-swarming by clipping all the queen-cells but one, soon after the prime swarm issues. This method is a good one in theory; but in practice, bee-keepers have found that too often the cell left will fail to hatch. Oftener the bee-master fails to get all clipped but one, and out comes his second swarm when he is least expecting it.

Practical honey-producers are asking for something else, and here is the system of management that I adopted some years ago, and advocated, and one which friend Hutchinson and others have tried and reported "O. K."

Let us suppose that colony No. 8 swarms June 15th. With a non-erasive crayon we mark upon the hive, "O, June 15," and on the hive in which we put the swarm, "S, June 15." Thus we distinguish the old colony from the swarm at a glance, as we make these marks in large figures.

When we hive the swarm (always on full sheets of wired fdn.), we place it on the old stand, moving the old colony a few inches to the north (our hives front east), with its entrance turned northward, away from its swarm about 45°. As soon as the new colony is well at work, having their location well marked (say two days), we turn the old colony back parallel with the new one. Now both hives face east, sitting close beside each other. While each colony now recognizes its own hive, they are, as regards all other colonies, on one and the same stand.

The dates on the back ends of the hives indicate that second swarming may be looked for about June 23d. About two or three days before that date, and when the bees are well at work in the fields, we remove the old hive to a new location in another part of the apiary. This depopulates the old colony, giving the force to the new, leaving too few bees in the old one for the young "misses" to divide; and as they at once recognize this fact, they fight it out on the line of "the survival of the fittest."

It is supposable, that when the old colony swarmed it contained two or three tiers of surplus sections, more or less completed. It is well to at once place part of them on the swarm; and when the final removal of the old colony is made, the rest may also be placed there: in which case there will be no loss of surplus by robbing the old colony of so many bees—not if your hives are properly constructed, arranged, and manipulated.

The old colony contains no very young brood, and very many newly hatched bees, so there will be no loss of brood by this operation—not in swarming time, in this locality and latitude.

In six to ten days the old colony will have a fertile queen, as a rule, and become quite populous when surplus receptacles may be adjusted to it.

In my practice with this method, and the practice of many others who have used it, I am not aware of one instance of failure. The plan embraces the advantages of speed and certainty. It is done in half the time you are reading this article. There is no hunting for queens or queen-cells, or even opening

the hives. It needs only to be properly executed to be appreciated.

If we are going to produce cheap honey at a profit, all our operations must be executed by just such simple, practical, and successful methods. We must manipulate hives more and frames less. All our hives must be readily movable, and we must make every thing work as nearly automatic as possible, and turn out first-class surplus honey.

Dowagiac, Mich.

JAMES HEDDON.

Friend H., although I have never tried the above plan exactly, from what I know of bees I should call it sensible in every particular. Of course, it includes natural swarming, and getting swarms down from wherever they happen to cluster, and may be that is as well as we can do. Well, where natural swarming is permitted, I do not know of any better way of managing than the one you give. I should think, however, the old stock would sometimes swarm, and send out an after-swarm, in spite of the treatment it had received. Will those who have tested the above, please report? for *now* is the time when we want to avail ourselves of such simple plans if ever.

HONEY-EXTRACTORS

MADE SO AS TO REVERSE THE COMBS WHEN TURNING EITHER WAY.

THE following was furnished us by Mr. F. Rignon, of Turin, Italy, who translated it from Italian into French, and our proof-reader has rendered it into English. The engravings are copied by our engraver from drawings of the machine, which was exhibited at the Italian Exposition held at Turin, in 1884.

The principle of centrifugal force was first utilized in dyeing, by means of the hydro-extractor, and afterward applied with great success by the noble Chev. de Hruschka de Dolo, in extracting honey from the combs without pressing them, thereby rendering a great service to apiculture. But, like all human inventions, it was susceptible of improvement. M. le Chev. Vassallo, of Castiglione, Moretta, Piemont, Italy, made one of these improvements in what is known as the automatic honey-extractor, which he presented at the Italian General Exposition in Turin, in 1884.

Till recently, to extract honey with the ordinary extractors it was necessary to reverse the combs, during which operation the combs were more or less injured. The Vassallo extractor overcomes this inconvenience, as the operator, by means of the impetus which he gives to the machine, to the right or left, can present the side of the comb from which he wishes to extract the honey, the centrifugal motion accomplishing the result.

At the Florence Exposition, as early as 1874, Mr. Vassallo presented an outline of his system, and for six frames; and in spite of the imperfections which appeared, he was awarded a medal of bronze.

The extractor for six frames is composed, first, of an outer tank, or shell, resting on four legs so as to leave room for a smaller receptacle to receive the honey, which runs out of the spout E, Fig. 2. The dimensions of the outer tank are: Diameter, 85 centimeters, or about 34 inches; depth at the middle, 40 c.; depth at the edge, 33 c. Resting on the bot-

tom of the tank is an upright shaft, F, 44 c. high, which carries, on its upper end, a pulley 10 c. in diameter, driven by a larger one 24 c. in diameter, with a belt. This last pulley is provided with a crank, which can be extended even beyond the periphery of the pulley, so as to render more easy the rotation.

CROSS SECTION VIEW OF THE EXTRACTOR, LOOKING DOWN FROM ABOVE.

Diverging from the axis F, at top and bottom, are six arms, G, Fig. 2, 30 centimeters long, and 30 c. apart at their extremities. These arms are bound firmly together by six small vertical strips, h, Fig. 2, at the ends, and by 12 other horizontal pieces, as shown at H, Fig. 1. Under the six frames there are as many open receptacles, made of wire cloth, as will receive the contents of a frame. These cups hold an official Italian measure; i. e., 31 c. long, 4 wide, and 22 deep. These are suspended to a vertical shaft, D, Fig. 2. This latter shaft is distant 25 millimeters from the upright stick h.

CROSS-SECTION VIEW OF THE EXTRACTOR, LOOKING AT IT FROM THE SIDE.

Beneath these receptacles is a pointer, or needle-shaped piece, which, on turning the crank, is made to strike on the tip of the little cone, which serves to turn the arms to the right or left, according to the impulsion given to the shaft F. These wire-cloth receptacles should be slightly inclined toward the center, so that they may not stop while against or opposite the drum of the machine. When the gearing is not in motion the leaves come to their

place of their own accord, pointing toward the center. See cut. To get the proper inclination of the frames, the lower arms, G, should be 5 m. longer than the upper, and let there be as much inclination to the shaft D.

Our readers can readily reduce the French meter to inches by reckoning 100 centimeters as 40 inches, which is not exact, but sufficiently so for this purpose.

This matter of making extractors so that the combs may be reversed when the machine is turned the other way, is very old. Perhaps it would be difficult to say whether it came up first in our own country or across the water. Most of these machines have been, however, after a time deemed impracticable; although where there are large apiaries, perhaps the machine may be found a labor-saving investment. Within the past year or two the matter seems to have been getting into practicable shape, and I believe there are a number of our American bee-keepers now using the automatic honey-extractors. We shall be glad to hear reports from bee-men who have used them a season through. The hexagonal form shown above, and adopted by our friends across the water, seems to have some considerable advantages. If I am correct, a machine to hold six Langstroth combs need be little if any larger than one to hold four, the combs standing on end, of course. Another thing, for so large a machine no pulleys nor belting is needed, nor arrangement of any kind for multiplying the speed. A crank attached directly to the center-shaft will give all the speed desired, and especially would this be the case where the extractor holds six combs instead of four.

FLORIDA.

ITS ADVANTAGES AND DISADVANTAGES FOR BEE-KEEPERS.

THERE seems to be much general interest among bee-keepers regarding any information about this State; and as I have spent considerable of both time and money in gaining what information I could regarding its adaptability to bee culture, perhaps a statement of the little knowledge I have gathered together may save others the trouble and expense of going over the same ground.

I want to say, however, that this searching after bee-knowledge in Florida has been a wonderfully pleasant work to both my wife and myself, and I am afraid we should be tempted to make a life work of it if we were able to do so.

Florida is alone and unique among the States of our Union, as regards nearly all the essential conditions of climate, soil, productions, etc.; and on this account one can not hope to convey any thing like a correct impression of the conditions existing there, short of writing a book; and even then it will be almost impossible for any one to get any idea of what the State really is, without a residence there of some time. It is hard for a person to understand any thing that is so radically different in nearly all respects from any thing we have ever seen, as is Florida; and for this reason, the State is almost always either over or under estimated by nearly every one, especially by transient visitors or short-

time residents. It will be readily seen, that no short sketch can possibly give much information, except to those who are already somewhat familiar with the State.

Again, the State is nearly 400 miles in length, north and south; and being nearly or quite on the frost-line, gives to different sections that peculiar difference in climate that makes a much more radical difference in vegetation than is anywhere else in our country seen in such narrow limits. Added to this is the fact that it is only within the last four or five years since able, intelligent bee-keepers first began to study the honey-producing flora of the State, and it can readily be seen that no person is yet able to give much more than a glimpse of the actual honey resources of the State.

Of course, the first thing any one intending to keep bees in Florida needs to do is to become familiar with its flora, which varies much in different parts of the State, and still more so on the different kinds of land. A description of these different kinds of land can be found in any description of Florida, so I will name only the most important kinds in the order of their general value; viz., high hammock, low hammock, scrub hammock, high pine, low pine, swamp, bay heads, prairies, etc. On the hammocks grow live and swamp oaks, cabbage palmetto, magnolias, hickory, cedar, and a host of other kinds of timber of lesser value, and a large variety of tropical vines, shrubs, etc. On the pine lands grow pine, two or three kinds of oaks of little value; scrub, or saw palmetto, gallberry bushes, wild pennyroyal, etc. In the swamps we find cypress, maple, ash, gums, shrubs, vines, etc. In the bay heads, nearly the same as in swamps, with the addition of different varieties of bay-trees. On the prairies, but little vegetation of value, unless it may be willow; and on the salt marshes along the coast, black and red mangroves, and a small plant whose name and description I can not give, but am informed is of great value as a honey-plant.

The rule is the same in Florida as it is elsewhere, that, while there are many different kinds of plants that give some honey, the real surplus is obtained from a very limited number. So far as we yet know, the following are the most valuable honey trees and plants in Florida, in the order of their probable value: Black mangrove, decidedly the most valuable of all, is found only on the coasts, where its roots can be moistened by salt tide-water, its extreme northern habitat being only a few miles north of Mosquito Inlet, on the east coast, and about the same latitude on the west coast. I could not learn certainly how far south it grows, but think around the entire south coast of the State. Its season commences about the 5th of June, and lasts some eight or nine weeks, and yields very largely. Cabbage palmetto comes next in value, its time of flowering being from about June 1st until Aug 10th. Saw palmetto and the gallberry bush are next, their season being a little earlier than the first named. Wild pennyroyal, as the natives call it, is, I think, a very valuable plant; its season is from the 1st of January to the middle of March. Bay-trees are also said to be quite valuable, but I could learn nothing positive. I also heard of a species of palmetto bearing blue flowers, and said to grow on the extreme south-west coast, that is valuable, but I am inclined to think its existence is more of a myth than a reality.

In addition to the plants named, are many others of more or less value; but the above are, I think, the most valuable ones. Many have had high hopes of securing large crops of orange-blossom honey, but I do not think the orange-bloom will prove any more valuable than is our apple-bloom here, and probably not so much so. The quality of the honey varies as elsewhere, according to the source. That from mangrove stands at the head for quality as well as quantity, it being peculiarly clear and white in appearance—more so, if any thing, than any honey we obtain in the Northern States east of the Rockies. What distinctive flavor it has is neither so strong nor marked as either white-clover or linden honey; and while this may be an objection to some, to others it is otherwise. Many persons, myself among the number, prefer the mildest-flavored honey we can get; and to such I think mangrove honey may be preferred even to white-clover honey. Cabbage-palmetto honey is very similar to that from mangrove, but not quite its equal, I think. That from the other sources I have named will none of it be ranked as white honey, neither is it generally as dark as buckwheat honey.

Honey of all kinds in Florida, so far as I have observed, is thinner and of less body than our Northern honey; but this is easily corrected by the use of sun evaporators, these being easily operated in that land of sunshine.

Before I enter on the important subject of location, it may be well to give a sketch of our personal wanderings in different parts of Florida. The first winter we spent a few days at Lawley, in Bradford Co., near the center of the State. The land at that place is nearly flat pine lands, interspersed with small bay heads, and is the richest pine land I have seen in Florida. We passed the largest part of the winter, about ten weeks, some 16 miles nearly east of Tampa, in Hillsborough Co. This is a high pine-land country, interspersed with occasional very rich hammocks, also swamps and prairies. We stopped while there with a taxidermist whom I frequently accompanied on his hunting excursions in different directions in the surrounding country. I also went a few miles west of Tampa, to the shores of Old Tampa Bay, where Dr. J. M. Price, formerly of Buffalo Grove, Iowa, then owned some bees, although not at that time there in person. We were also at Manatee and Bradentown, on the Manatee River, and stopped one day at Cedar Keys.

The second winter we spent some time at the same places we did the first winter; also stopped a day or two in Jacksonville, the same time in St. Augustine, some four or five weeks at New Smyrna, where we met the first and only genuine bee-keepers we saw while in Florida! While stopping here we (wife and I) were so fortunate as to make part of a small party who chartered a five-ton sloop on which we cruised some 150 miles south, being the entire length of Hillsborough and Indian Rivers, to Jupiter Inlet and back again. These rivers, or, more properly, lagoons, run near the coast their entire length, in some places less than 200 feet separating their waters from those of the ocean. This trip lasted four weeks, and was the most enjoyable experience we had while in Florida.

Unfortunately our party were none of them interested in bees, except ourselves, and we couldn't ask them to stop and allow us to examine special localities as thoroughly as we wished to; yet we obtained a fair general idea of that part of the east

coast of Florida. We learned from personal observation, and from information obtained by a free use of the Yankee trait of asking questions, that the growth of mangrove quite abruptly terminated some 15 miles south of New Smyrna, occurring again, but not so profusely, at the head of Hillsborough Lagoon. A small fringe of mangrove grows in places along the edge of the Indian River, until we get to the mouth of the San Sebastian River, nearly opposite which commences the islands which form Indian-River Narrows, these islands being covered with mangrove, and extending from ten to fifteen miles along the river to nearly opposite Indian-River Inlet, near the site of old Fort Capron. But little mangrove is found from here until we pass the mouth of the St. Lucie River, and enter Jupiter Narrows, where is another collection of islands covered with mangrove. This is the last place north of Jupiter Inlet where mangrove is found in any great quantities, and we found it utterly impossible to learn any thing about the growth of this plant south of that point.

There are two species of mangrove, the red and the black, both growing in very similar situations, only the black yielding honey. Prof. Cook says this is not a true mangrove; but as that is the only name it is commonly known by, I will continue to call it that. The red variety usually grows on the edges of the islands, with its roots partly in the water, while the black grows more in the center of the islands. This fact of the black being partially hidden behind a fringe of the red, prevented me from learning for certain how large an amount of black mangrove there actually is on the islands of Indian River.

This fact of there being two kinds of mangrove, both growing in the same localities, and somewhat resembling each other, entirely prevented our obtaining any information of value in reference to the growth of this valuable honey-plant on the south-east, south, and south-west coasts of Florida, although diligent inquiries were made of every one we met, who was familiar with those sections. Every one reported immense quantities of mangroves in different locations around the coast, but not a single person could say whether they were the red or black varieties. By far the largest amount of mangrove in Florida will, I think, be found on the south-west coast between Charlotte Harbor and Cape Sable; but whether there is a single stick of the black variety among it all is more than I could learn.

Mr. Hart, of New Smyrna, whom all your readers know of, told me that he hoped to spend a winter in the near future in making a cruise around the Florida coast from his place to Charlotte Harbor, investigating the honey resources of that section. When he does this we can depend on reliable information from a section which may prove almost a second California. I also hope to be able to make a similar trip some time. In all I may say when speaking of Florida as a whole, I do not include the extreme north-western part of the State. For reasons not necessary to detail, I have never tried to obtain any particular information about that section.

I believe that nearly or quite all experienced bee-keepers who have had the best opportunities for getting posted about Florida have come to the conclusion, that, to obtain large paying crops of honey year after year, one must be located within reach

of mangrove. For queen-rearing I should prefer the interior part of the State, I think. Good mangrove locations are, so far as we yet know, few in number, and of small extent each. That at New Smyrna, already quite fully occupied, extends in a narrow line up and down the coast not to exceed 25 miles, while the other three or four known locations between that point and Jupiter Inlet are of still less extent each. The probabilities, however, are that large numbers of excellent locations exist in the unknown regions of the State—unknown at least so far as their honey resources are concerned. It will thus be seen that, while those bee-keepers who are located in New Smyrna have met with splendid success, the chances for indefinitely multiplying those successes are as yet a problem of the future.

Concluded in next number.

A FEW MORE WORDS IN REGARD TO HIBERNATION.

PROF. COOK ALSO TALKS TO US ABOUT "TONICS" FOR BEE-KEEPERS.

MR. EDITOR:—The article from Bro. Clarke surely calls for a reply from me. In my cards on which I have notes, I find this: "Kirby says bees do not hibernate." Reference is given to *Ency. Brit.*, and to his Introduction. I did not look up the reference, but quoted as given in GLEANINGS for May 15th.

In Kirby and Spence's Introduction, Vol. II., p. 446, we find this: "Lastly, there are some insects which do not seem ever to be torpid, as . . . and the common hive-bee." This reference is where I presume I got my reference, as in *Ency. Brit.* it is stated as Bro. Clarke notes: "Bees probably never hibernate."

In the Introduction it is stated, on the authority of Huber, that bees are never torpid in winter, "but keep themselves in motion to preserve their heat." He also quotes Swammerdam, Bonnet, and John Hunter, to the same effect, while Reaumur is quoted as arguing that bees are torpid in winter, and take no food. In summing up, it is stated that "this usually most accurate of observers (Reaumur) has in the present instance been led into error, chiefly, it is probable, from the clustering of bees in the hive in cold weather; but which, instead of being, as he conceived, an indication of torpidity, would seem to be intended, as Huber asserts, as a preservative against the benumbing effects of cold." Kirby closes by saying, "Bees, then, do not appear to pass the winter in a state of torpidity in our climate, and probably not in any other."

Thus while I was unfortunate in my reference, I do not think I misquoted Kirby. Very likely, Mr. Editor, you will think enough has been said, and will be quite right in so thinking; but I wish to add, that, as I understand hibernation, it is torpor, attended with fasting, and is not thrown off by still greater cold. Now, I find bees always have a specific heat much above the outward temperature in winter; that in coldest weather I have noticed that they are constantly moving, and that a sudden chill in the outside temperature, instead of deepening their torpor, causes them to become more active, to eat more, and induces a rise in the temperature of the hive, as shown by a marked rise of temperature

in the thermometer, the bulb of which is in the cluster.

IS IT BEST TO HAVE GLEANINGS "ALL BEES"?

May I add my say in the criticisms of my friend Hutchinson as to GLEANINGS? Our physicians sometimes give iron as a tonic in case of pale, frail patients. They note the return of color, vivacity, and strength, and bless God that iron has a place in therapeutics.

Now, Mr. Editor, I take it that you have found this iron tonic, else why the astonishing growth and vigor of GLEANINGS? The doctor has proved that his patient needs the iron, so you have proved that the bee-public craves more than bread alone. Were I asked to explain the thrift and vigor of GLEANINGS, I should say it was the vigor and earnestness of the editor, aided by the very variety which fills its pages, and which is occasionally—very rarely—complained of.

I was talking to a subscriber to GLEANINGS a short time since about another bee-paper of which he knew nothing. Said I, "If you are so anxious to know its character, why not swap off and take it for a year?" He quickly replied, "Never! I will never give up GLEANINGS! but I will take the other also."

It were very foolish, I think, when a doctor finds the iron tonic, and proves its value, to throw it away; and just as foolish for you to let loose one jot of that which has given you such a hold on the bee-keeping world. My advice, then, is, don't omit the tonic of variety, which has helped to broaden every reader of GLEANINGS.

A. J. COOK.

Agricultural College, Mich.

Thank you for your kind words, friend Cook. In the matter of hibernation, it seems to me it is more a difference of opinion in regard to definition of terms than a difference of opinion in regard to the way bees winter. But in regard to your concluding kind words, it only makes me fear that I am not deserving of all you say. May God help me, and give me wisdom in choosing wisely, where there is so much going on all around us to choose from.

A SIMPLE WAY OF ITALIANIZING.

SOME OF THE REASONS WHY THE SIMPLEST WAY IS NOT ALWAYS THE MOST PROFITABLE.

WHERE I to have two colonies of bees (one of Italian and one of black), each with a good supply of brood, and I kill the queen of the blacks, and give them the entire brood of the Italians, and the Italians the brood of the blacks, would I Italianize both?

Osage, Ill., May, 1885.

C. M. THORNTON.

Yes, my friend, your colonies would both be Italians in a short space of time; that is, providing your black stock raised a queen from the Italian brood, which they would without much doubt. The plan as you suggest it is a very simple one, but it is too wasteful to be generally practiced, for we have a colony of bees wasting their time in perhaps the best part of the season, while they could make a queen-cell and wait for the queen to get to laying. Every day counts with bees—especially during a honey yield. Now, let us see how you can improve upon the plan by saving time. You can take a couple of combs of brood from your Italian

comb, and a pound of bees from your black colony, and they will raise a queen and get her to laying just as well as to keep the whole stock employed in doing this. After the queen gets to laying, remove your black queen, and take the queen from the nucleus, and introduce to them. This ought not to take over 48 hours, while by your plan it would take two or three weeks. It is always poor economy to keep a strong colony of bees waiting for a queen to be raised in the usual way. This is where the advantage of having nuclei comes in. Whenever a queen is lost, or one is to be replaced, we should be able to get a queen from some nucleus or some weak colony. After-swarms often furnish an extra queen when wanted, and on this account I think it is well to hive and care for every after-swarm, although it contains no more than a pint of bees. If you can not get a laying queen, a queen-cell makes us usually a full week ahead, and we can often get queen-cells from some colony that happens to be raising cells, or some colony that is preparing to swarm.

ANOTHER REASON WHY IT PAYS TO TAKE A BEE-JOURNAL.

KEEPING BEES AS A SPECIALTY, OR HAVING OTHER KINDS OF BUSINESS.

ABOUT the first of last December I was tempted, by seeing a copy of GLEANINGS, to send you my subscription for same, and now I can not see how I did without it or how you can afford to furnish such a practical journal for the price. But while you have gained my future subscription, you have lost my order for sections, as I find by a manufacturer's advertisement in GLEANINGS that I can buy close at home, and yet I had to go to Ohio to find out that fact.

Of my 40 stands, but 30 produced surplus honey; but the 30 produced over 1250 lbs. comb honey (we extract none), in boxes holding 12 to 15 lbs., worth 12½ cts. per lb., or \$155. My total expense for surplus boxes, marketing, etc., I estimated at about \$30.00; net profit, about \$125.

I did not expend over a week in attending to my bees all summer; but I gave them attention at the proper time. I laid down the grain-cradle in the midst of harvest, to make and put on extra surplus boxes, so as to keep the busy little fellows at work, and right faithfully they did it, rolling in the nectar sweet while I was binding the golden sheaves.

You see, I am a one horse farmer, and I also grow fruits, strawberries, grapes, some wheat, corn, hay, and garden truck for sale. I believe in mixed husbandry. During the winter I am engaged in teaching, one mile from my home. I am busy every day in the year except Sunday, and partly that day also, as I have a class in our Sabbath-school. I don't know any thing about hard times, as I keep my hands and brain busy, work hard, sleep soundly, keep a clear conscience, follow the golden rule, drink no intoxicating drinks, neither smoke nor chew, keep my barn well filled, have a wife well willed, and an only son, an excellent lad who is a young bee-keeper.

For some years I used the American hive with its sunken top, but found that a nuisance, and cut them all down to a level top.

My neighbors wonder how I get so much more honey than they. Why, by simply keeping them at work while the honey lasts. When the honey season is over, no use to give empty cases. I always keep an empty honey-case on top of the brood-chamber, in winter time, for upward ventilation, as I find that, where the brood-chamber is covered tightly, the combs get quite moldy toward spring. I think my bees have paid me more than 100 per cent per year since I have had them, but I don't think it will pay nine out of ten who engage in bee-keeping to depend on bees entirely for a livelihood. I never calculate on any net proceeds from my bees until I have the honey crop stored. As an adjunct to other things I feel sure it will pay those who give them proper attention. Count me as a subscriber to GLEANINGS as long as I keep bees.

Green Spring Furnace, Md. E. G. KINSELL.

JONES BEE-ENTRANCE GUARD.

DIRECTIONS FOR USE, AFTER SEVERAL YEARS' EXPERIENCE.

THIS device is to be placed over the entrance of the hive in such a way that the projecting pieces of zinc, which look like teeth, rest directly on the bottom-board. These teeth-like projections will be easily recognized in the cut below, although we make them with a square wooden block at each end now, instead of having them all of metal, as shown in the picture. The implement had

ENTRANCE-GUARD FOR SEPARATING DRONES FROM WORKERS.

better be fastened in place by a couple of screws or light nails. If used on a chaff hive you will have to fasten a little strip of board just below the entrance; for the portico hive, it rests on the alighting-board just as it is. To use it on a Simplicity hive, you will need the alighting-board shown below.

ALIGHTING-BOARD FOR SIMPLICITY HIVE.

Cut away the outside corners of each of the three corner-blocks until the entrance-guard rests on the alighting-board. Fasten it as before, then move the hive forward until the front end of the hive strikes the entrance-guard. If any other hive than those mentioned, modify according to circumstances, as per directions above. After having it fixed over the entrance, perhaps the simplest way to dispose of all the drones is to remove all the combs from the hive, shake off bees, queen, drones, and all on the ground in front of the hive. Put back the combs and replace the cover. The worker-

bees will crawl through the slots in the zinc, but the drones and queen will be left outside. Pick up the queen and put her in the hive. Let the drones all remain until next morning, and you will find them in a compact cluster. Feed them to the chickens, or destroy them as you choose. The arrangement is supposed to prevent swarming, by keeping the queen in the hive, so that the bees will come back as soon as they discover she is not with them. I believe it does not always work just right for this purpose; but for disposing of drones, there is no trouble. Where you want to restrain queens, the alighting-board on which the trap rests must be smooth and flat, or the queen will squeeze out where there is a little irregularity in the wood.

The price of the above drone-trap is 10 cts.; 10, 75 cts.; 100, \$5.00. If wanted by mail, add 2 cts. each extra.

RECENT DEVELOPMENTS.

And Suggestions and Queries Particularly Pertaining to the Season.

A PROMISE OF MORE HONEY-DEW HONEY.

I NOTICED this morning more honey-dew than I ever saw before in all my life put together; it is actually beyond all human calculation. If I had not seen it myself I could scarcely have believed it to be possible, for all the trees appear to be one entire coat of honey-dew all over the leaves, every part and particle being smeared with it.

J. Y. McCracken.

Rosebud, Ala., May 15, 1885.

SORGHUM FOR BUILDING UP IN THE SPRING AND SUMMER.

Is good sorghum safe and good for feed at night, to build up colonies? I can furnish it at 40 cts. per gallon.

J. C. STEWART.

Hopkins, Mo., May 9, 1885.

Friend S., you can feed sorghum or any thing else, providing the bees will take it; and during a dearth, when they are not gathering stores they will sometimes take it with great avidity. Be careful, however, that it is all used up for brood-rearing, or it might get into your honey for winter stores, or, worse still, your honey for market. Several years ago, when there was a dearth of honey between fruit-bloom and white clover, we fed several barrels of cheap maple sugar, so poor that bees would not even touch it at other times.

COMMON BEES BEST AT SOME TIMES, AND ITALIANS AT SOME OTHER TIMES.

I wintered my bees outdoors, packed in chaff; had 78 colonies in the fall; 25 of these were artificial, not much better than nuclei. I have 68 left. I should like to have friend Doolittle's opinion on the working qualities of the black and Italian bees. I think the Italians are best on basswood and thistle; the black, on raspberry and buckwheat, and about equal on white clover.

F. ROULO.

Portville, Catt. Co., N. Y.

Very likely you are at least partially right, friend R. This I do know: That the black bees will sometimes gather more dark

buckwheat honey than the Italians, although I can not say that I ever saw the blacks busy when the Italians were idle.

HONEY FROM THE WILLOW.

Bees are doing the best that I ever saw them at this time of year. I transferred 9 colonies into Langstroth frames, and had to extract the honey before I could do any thing with them. That was about ten days ago, and to-day all the hives are full of honey, bees, and brood, and four of them are working in the upper story. To-day they are working on willow, and they drop when they come in. Bees wintered very badly in this section; at least 90 per cent of them died.

F. W. MOATS.

The Bend, DeLancey Co., Ohio.

WHICH WAY SHALL THE ENTRANCE OF THE HIVE FACE?

The A B C tells us to set the hive of bees, when setting out, square with the points of the compass. Will you please let me know to which point of the compass the front of the hive should face?

P. K. PEREGRINE.

Amiret, Lyon Co., Minn., May 21, 1885.

Friend P., I can not discover that it makes any material difference which way the hives face. I have seen times in the spring when it seemed desirable to have them front to the south; but during extremely hot weather, the opposite direction would be somewhat desirable. All things considered, I think I should pay no attention to it. My remarks in the A B C were to the effect that you should have some regular system in placing your hives, that they might not be so disorderly arranged as to be painful to one who likes order. It is a bad plan to change the way the hive faces during the swarming season, for the bees are greatly annoyed and hindered by such a proceeding.

HOW MANY FRAMES ARE NEEDED TO CONTAIN ALL THE BROOD?

This day my bees are gathering fruit-bloom honey by the loads. The weather is fair, and not any too hot. Drones have been flying for some time. Most of my colonies have 5 to 7 frames with brood; a few have 8 frames with brood. One had 9 frames with brood. How would that be with an 8-frame hive? You know my hives all have 10 frames. My strong colonies also have queen-cells started, so I expect some new swarms soon. My strong colonies also have quite a bit of new honey in their hives already.

OTTO KLEINOW.

Detroit, Mich., May 21, 1885.

Friend K., if you made your bees fill a certain number of frames of brood, and made them fill them clear up to the corners before you gave them more frames, I think you could get all the brood there is in the best of your hives into eight frames, and still have room. Where we want to get the bees to put all the brood in the brood-frames, and all the honey in the sections, we wish to use the fewest number of brood-frames possible, and this is the reason why reversible frames have been talked about so much. By their use we can make the brood go clear up to the top-bar and clear down to the bottom-bar, and oblige the bees to put what honey they get, into sections.

He that is faithful in that which is least, is faithful also in much.—LUKE 16. 10.

MYSELF AND MY NEIGHBORS.

Discretion shall preserve thee, understanding shall keep thee.—PROV. 2:11.

ONE Sunday after meeting, while the boys were collecting in my class, I overheard some remarks in regard to the chickens which they each of them had at home. Quite an animated discussion was going on in regard to the merits of the different breeds, etc. Half an hour later, when their attention seemed to flag, and it seemed a hard matter to get them interested in the lesson before us, I suddenly woke them up all at once by taking for an illustration something that had to do with poultry-keeping. When they discovered that I could talk about Light Brahmas, Plymouth Rocks, and that I knew something about chickens, they were all on the alert; and if I did not teach the boys very much Scripture that day, I am inclined to think I got a hold on them that I had not possessed before. After the school was over, they plied me with a number of questions, and finally I told them I should be glad to have them come down and see my poultry-yard and Light Brahmas. A couple of them called a few days after; and finding that I had two hens on one nest, one of them made the remark that he did not believe I would have good luck if I let them go on in that way. Well, I did not have good luck. You see, the boy's judgment was better than mine. They seemed to do very well for a while, and each one kept on her own nest. The nests were so close together that, sooner or later, differences arose. One

thought the other had got some eggs that did not belong to her. Pretty soon some of the eggs were broken. The hens got soiled, and the other eggs got daubed with the broken ones; and as no chickens hatched from either hen, I finally concluded that eggs will not hatch when smeared over with any substance that closes the pores of the shell. I do not know whether my conclusion is scientific or not; but I do not want two hens on one nest any more. When I decided that the plan was a bad one, I just dropped one of the old Light Brahma biddies outside the inclosure of the wire netting. She walked around the yard, clucking for a day or two; and when she got over the sitting fever, I let her in again. The remaining hen stayed on her nest about a week over the regular three weeks. By that time she began cogitating in her mind (that is, if hens have minds) as to whether it was incumbent on her to waste any more time over those nasty, dirty-looking eggs or not. She evidently concluded there was not, for she got off her nest, and went and walked with the other hens, ate grass, drank water at the fountain, and sat under the shade of the evergreens. She stopped clucking, and behaved herself in a very sensible way.

Now, I have told you all this little story just to illustrate a point to which I wish to call your attention. These neighbors of ours, among the dumb brutes, even, have a certain amount of judgment, or wisdom or discretion, if we may so term it. I let the old hen stay longer than I should have done, because some of the eggs were laid in her

nest after she had been sitting a few days, and I did not know but she would succeed in hatching a few of them. Will it be safe to say she had *more* good sense in regard to the matter of continuing longer than I had? In going over to the house one day I passed her as she stood among the other fowls. She gave her tail a sort of wiggle, with a kind of self-satisfied air, as much as to imply, even if she did not say it, "I have done my duty as well as I knew how. In fact, I have done all that anybody could expect any honest, sober-minded hen to do. It is true, I did not succeed in getting any chickens; but I'm not going to worry about it, neither am I going to be so silly as to keep on clucking in a stubborn sort of way. I suppose the next thing to do is to lay some more eggs, and try it again, and I do not know why I should not be just as happy about it as if I had just succeeded in weaning a great brood of chickens, instead of having accomplished nothing at all."

An old horse oftentimes exhibits a good deal of judgment and wisdom. They have learned by many years of experience, how to do almost all kinds of work that horses usually do. There is a sort of dignity about them that I can't help admiring. Sometimes I feel like raising my hat, out of respect to an aged family horse. Yes, sometimes I feel more respect for him than I do for the man who drives him. Yesterday a friend was telling me of a horse they owned, who would cultivate corn all day, and not step on a hill, providing he was used well. He thoroughly understood his work, knew what was wanted, and seemed to take a degree of pride in doing it; but if some untrained boy undertook to jerk him around, and "holler" at him, he would get off his "hooks," as the saying is, and he would step on more corn in a little while than any horse you ever heard of. His dignity was offended, and his—I was going to say manhood, but I suppose it will have to be "horsehood," was outraged by setting somebody to manage him who had not as much good sense and understanding as the horse himself.

My friend, do you ever get angry at your horse? Within a few weeks we have been having a very bad piece of ground indeed down in the creek bottom and in the woods plowed up for the first time. I was afraid to set some of the hands about it, because they would get angry. Of course, the work was very perplexing, and it was pretty hard work to get the plow out of the roots, cut the roots off, and start in again, etc. I am glad to be able to say, however, that we have men here, good Christian men, who will take hold of almost any sort of a job of that kind, and I shall not be a bit afraid that they will lose their temper, jerk or scold the horses, or feel hurt toward me because I gave them such an unpleasant task. These men have wisdom and understanding. They have this rare quality of discretion. I complimented one of them on the patience and quietness which he showed in doing this hard work that I wanted done. He replied something like this: "Why, Mr. Root, it would not help things any to get out of pa-

tience. When one gets out of patience he does not get along as fast, nor do the work nearly as well." If the poor horses could talk, what do you think they would say about it? Did you ever see a bright, intelligent-looking, noble horse made miserable because some untrained, vicious man would swear and yell at him, and whip him? Mrs. Root says the greatest trial she has in this world, almost, is to see an angry or drunken man whip a horse. She says the only time she would like to fight is at such times as this. She would fight for the poor defenseless horses. I often tell her she ought to hire out to Mr. Bergh. Horses sometimes need whipping; but the Christian man, when he whips his horse, whips him with love in his heart—whips him not only to get the work along, but to make the horse better and happier. A horse that is made to mind, and that is made to understand fully *who* is master, is a happier horse than one that is not taught obedience.

Now, friends, I did not start out to write about horses, nor hens either, for that matter; but I started out to write about human beings; and as this paper is about as long as I usually make it, I think I shall have to take up the subject again in one of my Home talks.

Discretion shall preserve thee, understanding shall keep thee.

EPIPHYTYING.

MRS. CHADDOCK TELLS US WHAT THE WORD MEANS.

"EPIPHYTYING, epiphytying." I think I hear you say. "What is epiphytying, anyway?"

Well, an epiphyte is a kind of air-plant that grows on other plants, but does not derive its subsistence from them; and when we take baskets and boxes and old case-knives and go off to the woods to gather these air-plants we call it "going epiphytying."

Harry—did I ever tell you any thing about our Harry? I've been trying to ever since Mr. Root began to talk about Huber; but I don't believe there has been a word printed about him yet.

Well, last Sunday afternoon, after we had been to Sabbath-school and church in the forenoon—had driven home (five miles) and had our dinners and rested awhile, then the restless fit began to seize the children, to take a walk, to go somewhere, or do something; and Harry said, "Let's go epiphytying;" and we were so pleased with his use of the big word that we gathered the baskets and knives, and went. Harry will be five years old in eight days from now; and when I objected to the long walk on the plea of being tired, Harry said, "Oh, yes! do go, mamma; please do; you can lean on me."

After we started we found that the wind had changed, and we had to send back to the house for more wraps, while we sat on the fence and waited. Then we tramped through wet spongy fields of grass till we reached the timber and the epiphytes, and then such running and calling to each other! "Here's red ones! come quick;" "oh do come here! see this; it is the very prettiest one yet," and they ran from one old rotten stump to another, and some of the trees in the thick woods had them on the north side, away up to the branches. These

were mostly the common kinds—the flat green and gray discs that spread over old rails, and on tree-trunks in all damp places. We found numbers of what we used to call “clocks” when I was a child. We took them and marked the hours on them with the hands pointing to dinner time, and set them up in our playhouses. We found many red ones of the kind, and they were all small and much prettier than the white-faced ones. We found one that looks like a pansy—purple round the edges, then shaded gray, only these are all double, and I never saw a double pansy. These, Minnie says, are “rare;” and among her collection there are only four or five; then there is a little horny kind that looks like miniature deer-horns.

Well, they filled all the baskets and boxes, while I sat on a log and read a paper. When we started home we tried another path, and it led up a north hill-side where the frost was not yet out, but the ground was soft for an inch or two, and we went slipping and sliding every which way; and here it was that the assistance of my escort was needed, and he came gallantly to the rescue.

“Come here, mamma, come here; here is the best way; here, I’ll hold to this tree, and you take my hand, and I’ll pull you up.”

The tree that he took hold of was a hazel-bush, and I let him help me.

Minnie is scientific. She has a collection of plants and flowers, a collection of insects, and now she is making a collection of epiphytes. She has 32 different kinds now, and she has had it only six weeks. One of her specimens is the long gray moss that I got off a tree on the overflowed banks of the Mississippi last spring.

MAHALA B. CHADDOCK.

Vermont, Ill.

Well, my friend, you have taught me something that I didn’t know before. We always call these fungoid growths which you describe, by the general name of “punk,” and we boys used to gather it and peel it into strips for lighting fires. Our parents used to employ the same material, or something similar, for getting fire from flint and steel. I wonder how many of the boys nowadays know that a fire may be kindled by striking a piece of steel across the edge of a flint. In regard to these epiphytes, there is something that is very wonderful about them. They grow very quickly; and if you break them in two, you will find that they have a fibrous structure like other vegetation; but it looks odd to see the fiber running cross-wise of the plant. I never thought of using them for clock-dials, but I have noticed the pearly whiteness of some of the half-round ones. They seem to grow from a sort of colored water, charged with vegetable matter, which collects something in the way the stalactites form in Mammoth Cave; and in damp woods the growth is so rapid you can almost see it move. Some years ago I determined to go to my Abbyville Sabbath-school during a soaking rain; and on my way back I was rewarded by a sight of epiphytes really at the business of growing. I took a short cut through a piece of woods to save time; and while getting over a fence I noticed a dark brownish liquid oozing from an old log. The liquid was so thick with this old vegetable matter that a sort of scum, or transparent covering, had formed

around the liquid. This jelly-like covering was something like transparent leather or oil cloth, and the vegetable fibers were growing on it while I looked on. After what you have told in regard to these, I shall look on them with more wonder and curiosity than I ever did before; in fact, I am itching just now to go off into the woods and study up the subject. Can you tell us “children” of any books that treat on the subject? I am astonished to know that these are really air-plants; for since you mention it, from what I find in Wood’s Botany it seems they would come under that class.

WORKING TO THE LINE.

Not with eye service, as men-pleasers, but as the servants of Christ, doing the will of God from the heart.—EPH. 6: 6.

NOT long ago there were some carpenters working at our house; and as one young man went to fit the window-casing he had some trouble with it, and I said to the head carpenter, “What’s [the matter?” He replied, “He did not saw to the mark where I marked the board,” so you see the consequence was, the board was spoiled and the time lost.

The thought at once struck me, how many there are in this world who can not be guided by the line! In their haste or indifference or recklessness they go wide from it. Now, a good servant is as faithful when his master is away from him, as in his sight. Some day this young man will come to realize what a careless habit he has allowed himself to form; for if he wishes to learn the trade, and still continue in this way, in the end he will be only an indifferent workman. He will find it difficult to secure steady work. When “times are dull” he will be one of the first sent adrift, and the last employed when times improve. And all this comes from mere carelessness, mere inattention and lack of interest. It is just as easy to follow a line as it is to saw away from it. But one must use his eyes, and give his attention to what he is doing—that’s all.

But we can make a wider application of this than just to that young carpenter. When we see any one doing shiftless work, failing to put conscience into his work, thinking that will “do” which is only half done, I say you had better saw to the mark; for if you don’t, by and by the consequences will go hard with you; and, nine cases out of ten, you will go around grumbling at your “bad luck,” just as if there were anybody to blame but yourself.

I have seen clerks who were only eye-servants—very diligent when their employer was watching, but careless and neglectful the moment that vigilance was relaxed. I think you are not sawing to the line; some day you will have a peremptory dismissal, and find yourself loaded with a confirmed habit of shirking, that is very hard to get rid of. You will then see that it is always best to be faithful, even on the ground of self-interest.

When I see a scholar just fooling away his time—that is no word for it—not a “hard boy,” perhaps, as the school phrase goes, but just wasting the “golden hours” when he ought to be laying the foundation of a good education, “getting away” as easily as possible, instead of setting himself to master those studies, right here you see we find another who is faithful only in eye service. One of

these days that boy will regret those hours were so idled away. The general principle, in short, is to follow the line as nearly as possible, in every thing in which you wish to succeed. It is not genius that accomplishes great things in this world, although genius is God-given, and is a gift by no means to be despised; but it is a patient, earnest, exact work; it is following the line, right straight along its edge, doing the will of God from the heart; that is the true way to work; put your heart into it, not in the way of eye-service.

AUNT VIC.

Rockton, Ill.

Every boy or girl, under 15 years of age, who writes a letter for this department, CONTAINING SOME VALUABLE FACT, NOT GENERALLY KNOWN, ON BEES OR OTHER MATTERS, will receive one of David Cook's excellent five-cent Sunday-school books.

Many of these books contain the same matter that you find in Sunday-school books costing from \$1.00 to \$1.50. If you have had one or more books, give us the names that we may not send the same twice. We have now in stock six different books, as follows; viz.: *Sheep Off, The Giant-Killer, The Roby Family, Rescued from Egypt, and Ten Nights in a Bar-Room.* We have also *Our Homes, Part I.* and

Our Homes, Part II. Besides the above books, you may have a photograph of our old house apary, taken a great many years ago. In it is a picture of myself, Blue Eyes, and Cuddy, and a glimpse of Ernest. We have also some pretty little-colored pictures of birds, fruits, flowers, etc., suitable for framing. You can have your choice of any one of the above pictures or books for every letter that gives us some valuable piece of information.

"A chiel's amang ye takin' notes;
An' faith, he'll prent it."

ARE strawberries ripe at your house? They are not at ours, but we have great whopping green ones that Huber and I like to look at and admire almost every day. It keeps us quite busy picking the runners off nowadays. They are such great big strong ones that it almost makes me feel bad. It would be such fun to let them root into pots and get potted plants right off now, instead of waiting until August. But the old heads in the strawberry business say if you want nice large berries you must clip off the runners. One of our small boys does this with a pair of scissors and a basket. I have him put the runners in the basket, because I want to have him learn to be tidy and neat.

How are the chickens by this time? We make our chickens work. Do you want to know how? A while ago Mr. Weed was in real trouble because of the little green flies that got on his plants in the greenhouse, and we had more trouble outside of the greenhouse with little black fleas on the cabbage-plants. Well, Mr. Tillinghast said that a lot of little chickens among the cabbage-plants would chase and scare the black fleas clear off, every "last one" of them. Well, some chickens hatched, and we had a

nice coop made with wire netting over the front, so the old hen could see and be seen, and we just put her right down by those cabbage-plants. Sure enough, away went the fleas; and now we have fifteen or twenty thousand of the handsomest Jersey Wakefields and Winningstadts you ever saw. As the weather got warm, Mr. Weed raised up the short sash to the greenhouse, and the chickens hopped in and just "chuckled" when they saw those green flies on the tomatoes, radishes, and lettuce. They just went right in among the plants, and worked like little beavers, and pretty soon there was not a green fly anywhere. When they had finished one bed they would hop across the walk to the other side, and sometimes they would miss and get down the path. Then the engineer would help them up. But one day one little white chick (they are light Brahmas, you know) met a mishap, and went into the water-barrel. The engineer found him when he was apparently all dead; but he took him before the great fire under the boiler, warmed him up and dried him, and pretty soon he moved a little. After a while he got up and looked around, and in the afternoon he was chasing fleas and hunting flies as glibly as if he had not had that short but sad experience in regard to the vicissitudes of life.

One of our neighbors had 35 swarms of bees last summer, and 2000 lbs. of honey. I like to see bees swarm.

G. H. SWARTWOOD, age 9.

Tracy Creek, N. Y., Feb. 27, 1885.

PAPA'S HELPER.

Papa has 35 swarms of bees; 3 of them died this winter. We watch the bees to see them swarm. Papa gives us 5 cents if we see a bee swarm. He makes bee-hives to sell. I help him all I can.

JOHN I. EMIG, age 9.

Dandsburg, Pa., Mar. 29, 1885.

A LETTER FROM RED RIVER, LA.

I put up 77 of those frames pa got from you. I like to put up frames, but I don't like to work with bees, because they sting. I would rather raise chickens and ducks. Ma has 150 little chickens and 8 little ducks. We live on Red River, and it is rising very fast.

FLORENCE A. HARRISON, age 9.

Collinsburg, La., April 30, 1885.

FROM ONE OF OUR SIX-YEAR-OLD CONTRIBUTORS.

I am a little girl six years old, and have a little brother five years old, and he has been sick. I have a little sister one year old. Now I will tell you something about the bees. My pa had some bees, and they all wanted to hatch, so I went out there where they were, and one stung me right away on the arm.

FLORENCE WISEHEART.

Iola, Ill.

THE RESURRECTED BEES.

Papa opened a stand of bees a few days ago, and there was apparently no life in them, and there was no honey in the hive. Returning about an hour afterward, he found there was some life in them. He warmed plenty of honey, and poured it on the bees. He then heated a brick and laid it on the cloth, and now they are as lively as any of the bees. He calls it *resurrecting* them.

ESTA WILLIAMS, age 13.

Maysville, Ky., Feb. 11, 1885.

BENNY'S REPORT.

My papa began the year 1883 with 3 colonies of bees, and increased them to 15, and wintered 14, and increased them to 45, and then wintered 38.

BENNY MOSES, age 10.

Dupont, Minn., Apr. 25, 1885.

REPORT FROM A MISSISSIPPI JUVENILE.

I am a boy of 12 years old, and work in the field every day, and go to Sabbath-school every Sunday. We have about 15 acres of corn, and about 13 acres of cotton. We are going to get some bees as soon as possible.

H. D. BOOTHIE.

Caseyville, Miss., May 25, 1885.

ALICE'S REPORT.

This has been a very hard winter on our bees. We have 13 stands, and three of them died. We had five in the cellar. We fed them most of the winter. Some of them are very strong, and have a good bit of honey and brood. I am terribly afraid of them. Sometimes they come in on our porch and sting us. They never bother us when we make cider. My grandpa Stephens gave me a hive of bees, but I was so afraid of them that I sold them.

Cokeville, Pa., May 8, 1885. ALICE McBAINE.

WHISTLING DOWN A SWARM OF BEES.

I have one sister and two brothers. We live on a farm one mile and a quarter from town and school. Papa has five colonies of bees. Last summer as he was working in the garden he heard a buzzing noise, and looking up he saw a swarm of bees. He whistled, and they alighted in a tree near by. He lived them, and brought them home in the evening. My uncle, Mr. Sheldon, takes GLEANINGS. I am reading *Our Homes*. I think it is a very nice piece. My uncle has about sixty colonies of bees.

Independence, Iowa. LIZZIE WHITNEY.

CHARLEY'S PAPA'S "BEE-MILL."

My papa has about 50 bee-hives, and has lost 12 of them. I am a good little boy, 8 years old. I help my papa to tend to the bees. I go to school when it is good weather in winter, and help papa with the bees in summer time, and I go to Sunday-school every Sunday. Papa has got a bee-mill; he makes his own hives. I turn the bee-mill for papa. He says he is going to make a bee-man out of me. I help him bend the section boxes he gets of you.

Ellis Mound, Ill., March 1, 1885. CHARLEY HALL.

Very good, Charley: but, how about that bee-mill? I think it must be some kind of a mill to make bee-hives, only I do not see how a boy as young as you could turn very much. I am glad that you are a good little boy.

REPORT FROM "HOLLYWOOD" APIARY.

Sister Lillie began to keep bees with one small stock of Italians in the spring of 1883; later in the summer she bought a full stock of black bees. Next spring she increased to five; sold about eight dollars' worth of section honey. Brother made, at a small outlay, a good large extractor. This spring another sister bought a strong Italian stock, and the six increased to fifteen good-sized ones and two small ones. I hived the first three swarms during the absence of sister L., and she gave me the first swarm for my trouble. I was quite timid about them at first, as the stings do not agree with me at all; but the responsibility being thrown entirely upon me, I shouldered it as bravely as I could, and

am now fearless when well protected by bee-hat and gloves. Our bees are now "booming," and we hope to take a good surplus. GLEANINGS comes regularly, and is eagerly read and much liked.

Augusta, Ga., May 21, 1885. BERTIE NORRELL.

LETTER FROM A YOUNG CANADIAN ABOUT SWARMING.

I will tell you what I think about swarming bees. I would watch until they come out, and then follow them, keeping far enough behind them so as to be able to keep track of them; and when you see them settling upon something, stop and keep very quiet until they alight, then retrace your steps, and bring back where the bees are a small hive, then take a stick and shake them into the hive (this to be done very carefully); then cover up the hive with a white sheet, and leave it standing in the place until the bees that did not go in come back. Then carry the hive back to its usual place, and your bees are hived, and you have now one more hive of bees.

FRED TURNER, age 12.

Jarvis, Ont., Canada, April 30, 1885.

Very good, master Fred.

EULA'S LETTER.

My papa keeps bees. He has nine stands. We don't use any tobacco here, only mamma dips snuff. I go to Sunday-school every Sunday. I have two little sisters; one's name is Maggie; she is four years old. The other's name is Love; she is two years old.

EULA JOHNSON, age 13.

Cayce, Ky.

That is a pretty good letter, Eula; but I am sorry to hear that your mamma dips snuff. I do not suppose that many of our boys and girls know what dipping snuff means, and I do not remember that I ever saw anybody who did use it in that way, only I have heard of it. It is a tobacco habit, like chewing and smoking, but I believe it is confined mostly to women rather than men, and mostly to what we call "down South." I said, it is confined mostly to women, because I am pretty sure that our girls nowadays are not tobacco-users. Am I not right, Eula? Tell your mother, that if she feels that using tobacco is a bad habit, and is willing to give it up, with the customary promise, I will send her a smoker. If she does not work with bees, she can give it to your papa. I suppose, of course, your papa does not use tobacco, from what you say. I should think your mamma's breath would smell bad when she goes to kiss you, does it not?

OSCAR AND HIS COTTON PATCH.

I live with my grandpa, B. D. Kimball. I follow the farming business. I have a cotton patch, and it is coming up finely. I help my grandpa hive bees. I climb up in the top of trees, about 27 feet high, and saw them off, and let swarms down with a rope. They sting me sometimes. Grandpa gave me a hive. He received the crate of ten hives you sent him, in due time. We have eight hives from the one we received of you in 1883.

My school is out now. I have never been at school much. I learn at home. Grandpa takes your journal, and I like to read it very much. I like to read about your trip to New Orleans, and the cotton you saw and thought was some kind of weed. We have fine prospects for good crops. We

hope it will be a good honey year. Grandpa has in all 31 hives. The strawberries you speak of I never saw.

O. H. BAKER, age 11.

Blum, Texas, April 28, 1885.

Thank you, Oscar. I should really enjoy seeing your cotton-plants grow. I suppose if I come to see them with green leaves on I should not be so apt to call them "weeds."

JAMES' REPORT.

A bee-man who has been all over the county says there are less bees kept here than in any other part of the county. Many have tried it in box hives, and have failed, and are afraid to try the new ways, for fear of failing again. We have one of our honey-signs up, but our bees are kept by my aunt, three miles off. She took 90 lbs., mostly extracted, from one colony last season, which she thought was a good yield for the dry season, and the little attention they had, which was only to supply a plenty of empty frames of comb. She is trying to start a home market for her honey by leaving some at the stores and some to us three boys who she thinks will care to work with bees when we are older.

We have a No. 1 yoke of steers one year old. We work with them now, and it is fun for our visitors to ride in our cart when they come to see us. It would be nice to visit your factory, and see how big those boys are who work for three cents an hour, and how much they can do, and the older boys, and other things your paper tells of.

JAMES E. BRECKENRIDGE, age 13.

Watertown, Wash. Co., O., Apr. 11, 1885.

And so, friend James, I suppose if I should come to see you I could ride in that cart behind those young steers, could I?

BEES AND SILKWORMS.

I will tell you about our bees. We had 38 last fall; have 42 now. They are very slow in swarming. We lost two. I think the moths killed them. I live with my uncle, Mr. Hunt. I have been with them since I was a wee little baby. They have no children, and I am their little girl. My mamma and papa live near us. I have four brothers and two sisters. I can feed the chickens, milk the cows, wash dishes, and help about a great many things. I also feed the silkworms, and can wind the silk they spin, to knit my stockings, and to make my little brothers fishing-lines. The kind of silkworms we have are easy to wind off. Mrs. Hunt reels it; she has reeled a great deal for the people, and some of them she reeled for live up there where you do. We are raising eggs for the market this year. There are many wanting our breed of silkworm. Tell Miss Blue Eyes I could teach her how to wind silk. If you think I deserve a book, please send me your picture with that of Blue Eyes and Caddy.

LILLIE MITCHAM.

White Sulphur Springs, Ga., May 12, 1885.

Well, Lillie, it seems to me, although you say you will tell us about the bees, that your letter is mostly about silk and silkworms. I am glad to hear it, though, because you give me some new ideas in regard to silk culture. Some breeds of silkworms are better than others, are they? But, Lillie, when we give a picture we do not give a book, and when we give a book we do not give a picture. We decided to send you a picture where you can see myself and Blue Eyes and Caddy. That makes it all right, does it not?

THE WAY SYLVESTER AND HIS MOTHER SOWED ALSIKE CLOVER, ETC.

I thought I would tell you how we sowed our alsike clover. I grubbed up sod, and ma shook the dirt off and threw it away. We raked it all over, and ma sowed the seed. There was a woman from Florida visiting ma, who said snake-feeders killed bees there. SYLVESTER BABSON, age 11.

Lower Salem, Ohio.

If we are to understand, friend Sylvester, that you and your mother threw the dirt away that you shook off from the sods, it seems to me you did just the wrong thing. Sods are very valuable fertilizing material; and even the dirt that adheres to them is good for almost any growing plant. Turn your sods grass side down, and get some fine earth on top of them, enough to get your clover to start, and you will be sure of a good "catch," as the farmers call it. Greenhouse men buy sods in great quantities, and stack them up until they rot, so as to get real nice dirt for potted plants. If the heap of sods is wetted with soapsuds on washdays they will rot all the quicker, and it makes the nicest dirt you can get for potting strawberries or starting honey-plants. Some fine old stable manure mixed with the rotted sods is excellent for an addition.

THE DRONES WHOSE OWNER EXPECTED THEM TO LAY IN THE SPRING.

My father has 17 swarms of bees now. This spring he had four queens and about four quarts of bees. All of them have queens but one. There is an old gentleman who lives about a mile from our house. He has six swarms of bees. Three of them have drones yet. He says they are going to commence to lay early next spring. I have one pet; he is a cat, about 7 years old. If Annie picks him up he will commence to growl. Little Huber must have tough finger-nails to pull the corks out of the bottles. I should like to see him.

Cameron, Pa.

WILLIE WYKOFF.

Well, Willie, you knew better yourself, than to think that drones would ever lay eggs, didn't you?—It is not so much the tough finger-nails that Huber has, as it is the pertinacity with which he sticks to anything he undertakes. Yesterday I was startled by seeing the Waterbury watches, that hang in one of our store windows, flopping about as if they were alive. I started in alarm to see who could be swinging them around so. You see, it is warm weather now, and the window was up. Huber had climbed up on the outside of the window; and while he sat on the window-shelf he was amusing himself by taking down watches and hanging them up again. I set him down on the sidewalk; and while I was telling him how naughty it was to meddle with the watches without papa's leave, he grabbed hold of a big head of lettuce that we had in a box for a sample, and pulled off one of the nicest leaves. Then I had to commence another little sermon about meddling with things, and pretty soon mamma came along with his wagon. You see, when he runs away she goes after him with a little wagon, because she can draw him home quicker than she can lead him by the hand.

OUR HOMES.

In the beginning God created the heaven and the earth.—GENESIS 1:1.

For God so loved the world, that he gave his only begotten Son, that whosoever believeth in him should not perish, but have everlasting life.—JOHN 3:16.

IT was a warm Sunday night; in fact, a thunder-storm was approaching. The house was all still, and every one, I believe, was wrapped in slumber. The weather was so warm that baby Huber had not only kicked the clothing off, but, being restless, he had crawled down near the foot of the bed, with his head over toward an open window. He seemed a little nervous, even in his sleep, for the day had been an eventful one to him. He had attended the young people's prayer-meeting in the evening for the first time in his life. He had been at one meeting once before, it is true. You may remember I told you about it a year ago. It was the morning of the Fourth of July. Well, both Huber and his papa had been on a tease for several Sundays past that he might "go meeting with papa." At length mamma consented, and Huber sat on a chair by his papa's side, and was permitted to hold a hymn-book while he listened to the chorus of voices. He is fond of music; and when some of the pieces were unusually full of melody I noticed by the movement of his little white dress as he drew long breaths that the whole scene all together was stirring his little heart. Very likely he could not quite make out what the purpose was of having the meeting. He turned his head one way and then another, and looked at the happy faces, and doubtless concluded that the gathering was for some good purpose, even though his baby heart could not quite make out what the purpose was. So many nice ladies was a mystery to him. He calls them "ni' 'adies." As they caught his admiring glances, is it any wonder that he got back many a pleasant smile?

When he saw the rest bowing their heads in prayer, he seemed to catch the spirit of devotion as well as the spirit of song, and his little hand was raised reverently to his forehead while he bent his head as he had seen the others do. He did not know what it was all for, yet something in even his little heart seemed to say it was good to be there, and there could certainly be nothing wrong in bending his little head with reverence and respect for the spirit that seemed to be moving the hearts of this body of people. His mamma had said, over and over, when the matter was talked of, that he would talk out loud in meeting, and "holler" and carry on. He had not lisped a word, with but a single exception. When the meeting was about half over, while he was looking at the different things he saw with open-mouthed wonder, he chanced to glance at the large chandelier, and it was so much nicer than any thing he had seen at home, that he commenced an exclamation of surprise, but stopped short at a look from papa.

Well, the meeting was over, and we were all sleeping soundly, as I told you, until the noise of the thunder and the almost incessant

blaze of the lightning awakened him. He crawled up to mamma first, and then, contrary to his usual habits, turned over to where his papa was sleeping soundly. I was awakened by a piping little voice:

"Papa! papa!"

"What is it, my boy?"

I noticed that something was on his mind, and he was trying to give expression to it; but his brief vocabulary of words did not quite admit of hitting the point he wished to express. Finally he managed to make me understand. How strange it is, that we learn to define the purport of the few brief fragments of words that these little ones get hold of! What he said was this, as near as I can remember:

"Papa, where 'gettie'—where 'gettie'?"

"Where 'gettie' what, my boy?"

"Where?"—with quite a pause—"where 'gettie' thun'er?"

Now it was plain to me. He wanted to know what the thunder and lightning were for, and where they came from. The elements were making quite an unusual disturbance without, and the blazing of the lightning might call forth wonder and astonishment from any one, who did not sleep as papa usually does. That meek little voice wanted an explanation of the rumpus going on without, which papa did not seem to mind any thing about. Papa evidently seemed to think it was all right, and nothing to be alarmed about; but his little playmate (Huber and I are playmates, you see) could not quite understand it, and he felt pretty sure that papa would not object to being awakened in the middle of the night, especially when baby Huber seemed disturbed, and wanted so much to know about these things. How should I explain to him about the phenomenon of thunder and lightning? and especially, how should I allay the fears that were troubling his little breast? Papa had already told him about God, and had tried to instill into his little mind a proper idea of this great Father who, according to the language of our text, created the heaven and the earth.

"My boy, God made the thunder and the lightning, and it is all his."

He repeated it over after me, evidently to get a little more assurance, and then came a further interrogation:

"Hurt Huber?"

"No, my boy, it won't hurt Huber. It is God's thunder and God's lightning, and God loves little Huber. He loves papa and mamma, and he loves all the people that are good."

I had struck the point. His little mind was already groping and reaching up toward that great Unknown. I can imagine that it seemed to even his little mind that it could hardly be we are sent alone into this strange world without help and without protection, or that it could hardly be that there was nothing to satisfy this almost indefinable longing for sympathy and love from this "Great Spirit," as the dusky children of the forest would term it. He wanted to know about Him who holds the winds and waves and lightnings in the hollow of his hand, and who on earth could tell him truly about

these things so well as his papa? Papa had explained things to him in the fields; he had told him about things when we were out riding in the buggy. He knew his papa told the truth, because his papa had never fooled him nor disappointed him. When he told him that, in a few days, there would be nice berries on the strawberry-plants, he knew it would come to pass. Yes, on that very Sunday morning he and his papa had had a jollification over finding some great ripe strawberries, right where papa said they would grow. A great many things papa could manage and control. He could make old Jack behave, and he could make the machinery mind at the factory; but this thunder-and-lightning business evidently was something that papa did not start, or had not much to do with. How did it come, and what was it for? That was what he wanted to know; but the best way he could manage to frame the thought, from the stock of words contained in his infantile vocabulary, was as he put it, simply "Where 'gettie'?" Papa's explanation was sufficient. The thunder and lightning were God's, and God was the one who made the "great big sun," and the stars "away up high;" who made even papa and mamma and Huber. These were great truths, but they were hardly satisfying. An elephant is great; but if we were alone with him in the woods, a more important question would crowd itself upon us—Is he friendly? A horse is not only great and powerful, but he is handsome. He is nice to look at. These qualifications are good so far as they go; but the more important question is, "Is he kind and gentle?" especially if we are to be placed in his power. It helps us to know that God is great; but it satisfies us infinitely more to know that he loves us. He created the heaven and the earth, it is true; but, how about poor weak helpless human beings, such as we are? Does God love us? When he fashioned us from the dust of the earth, he also framed the heavens, and gave the thunder and lightning a place in the universe. Had he any plan in regard to these things, or was it all framed without plan or purpose anywhere? Did we enter into his plans any more than the thunder and lightning? and are we of any more account now than they are? Does he care if they crush and devour us? O my friends, to be sure, he cares; "for God so loved the world." What a beautiful, beautiful text is this, and some way it satisfies me, and makes me happy, to turn from this first verse in the Bible over to the third chapter of John, and to that sixteenth verse. I am told that others have found comfort in that sixteenth verse as well as myself. The stenographer who is taking down these notes says he has a copy of that verse in 240 different languages. Why was that verse singled out above all others, to be translated so that all nations of the earth can read it, even if they can not read the rest of the holy word? Why, because that verse is of such wonderful import and importance to the children of men. While I think of it I rather expect that Huber will love that verse above all others. What a wonderfully pleasant task

it is to teach these little ones these great truths! When I talked to him there in the darkness of the night, and assured him of God's love, while I allayed his fears with my hand on his little confiding self, what a glimpse I had of God's love *myself*! It seemed to me as if God were pleased to have me state so positively that there was no mistake about it. He loves us; and even though he should see fit at times to let the lightning strike us, and even though we may be called upon to endure death by the devouring elements, still that great love is there, and his presence and his Spirit shall be with us in the hour of trial, bridging over the dark stream—the only conditions being that we trust and obey him.

Huber is sleeping again. He is resting on that great truth that his papa unfolded to him. How do I know it? Because in his sleep several times I heard the simple little words, "God loves Huber." He had taken the statement from me as a fact, you see, and the fact satisfied him. He did not understand it quite all; and before he had got quite soundly to sleep he sometimes got things mixed up a little; and as I listened once to hear what it was he was saying in a dreamy sort of way, after the words "God—loves—Huber" then came still more slowly, "thun'er—loves—Huber." You see, the fear of the thunder had been allayed by the thought that it was one of God's creatures—one of his servants, entirely subject to him; and if God loved Huber, is it any thing strange that, in his infantile mind, he in his sleep cut the matter short by the expression I have quoted, and resting on that thought went to sleep and slept soundly till morning? Would it hurt any of us if we rested on just such a childlike faith as that—a faith in God? "Except ye become as little children," etc.

Now, friends, such thoughts as the above were often in my mind when passing through Mammoth Cave; and when somebody suggested that those great rocks might fall and bury us up, a sort of feeling came up at once, if they do, God is near: "fear not, little flock."

To take up the thread of our story where I left off last month, we will finish our trip.

"Danger on the right!" sings the guide once more. "The Fat Man's Misery," announced the guide. Now, I expected to see something unpleasant; but, imagine my surprise when we entered the most beautiful portion, to me, of Mammoth Cave. Of course, we had to stoop and be squeezed to some extent, but we went down a beautiful winding way, with a nice level path under our feet, with carvings and formations rising at our sides, perhaps waist high, that seemed as if they must have been carved out for ornamental purposes. Some of it looks like a pretty garden fence. Again, there were beds spread out at each side, something as you see them in a greenhouse, and the carvings in stone would answer the purpose of flowers. One instinctively passes his hand over the flutings and moldings as he turns this way and that in this narrow, rocky cavern. There has been an attempt made to change the name to the Winding Way, but

the name does not stick. This passage is 250 feet long, and turns abruptly eight times. We find waves and ripples in the petrified rock. This passage is very interesting to blind people, because they can pass their hands over the rocky formation without trouble, and take in its wonderful beauty.

From Fat Man's Misery we emerge into what is called "Great Relief," for we have plenty of room to spread out and hold up our heads. It used to be thought, that if this close passage were blocked up there would be no means of escape from the regions beyond. In 1871, however, William Garvin, the colored guide, discovered a short cut known as the Corkscrew; and after you have climbed through it you would be willing to decide that the name is appropriate. It is a sort of clamber over loose rocks, twisting first one way and then another, winding around like a corkscrew, and then winding the other way, but all the while going upward. Occasionally you look through the crannies in the rock, and see your comrades with the lanterns away down at the bottom of a well below, as it were. The distance is altogether 150 feet. Sometimes you climb short ladders, again you spring from one rock to another, the guide catching you by the hand as you alight, that you may not slip off. Care must be taken that loose rocks are not rattled down, lest they strike your comrades below. In going back to the mouth of the cave this corkscrew ascension saves about a mile of travel. Oddly enough, you squeeze through a fissure and come out among the Kentucky cliffs near the ceiling; in one of those vast rooms where we hung our overcoats when we started in.

We are not ready to go out yet, however. The guide takes us off in another channel, and shows us Odd-Fellows' Links, which are in black on the ceiling of the cave. Then we come to Bacon Chamber, which awakens a laugh from almost every one who sees it, for there, hanging down just so as to clear our heads, are veritable smoked hams—smoked hams in shape and size, and smoked hams in color. When we touch them they feel like smoked hams. I suppose they have become greasy from being handled by so many fingers in the years past. I looked at them again and again, and each time it seemed more incredible that these things could have been formed thus by the passage of the water.

Now we go down to Lake Lethe and Echo River. The guide produces a tin dipper, and we take a drink of these famed waters. It is just a still body of water, away down in the darkness. The guide shouts, and the strange echoes come back to us. Then others shout, and we know now why it is called Echo River. This river comes out at the point where Ernest and I discovered it the night before in our rambles. The way they prove it, they throw chaff into Echo River, and it comes out at the hillside where I have mentioned. The eyeless fish and the lobsters are to be seen only in the long route. But they are always to be found on the tables where other samples are kept at the hotel. They are put up in alcohol, in little bottles at 50 cents a bottle. Here we have a room covered with snowballs, and one is al-

most irresistibly forced to believe that a lot of schoolboys did it for mischief. But there the snowballs stick, and have stuck for ages. They are crystallized plaster of Paris.

And now, friends, we are informed we are at the end of our trip. A feeling of sadness comes over me—sadness caused by the thought that this wonderful experience of the past two or three hours has come to an end. As we near the mouth of the cave, the breeze strikes us again, and the temperature reminds us that it is winter. The boys catch their bats, and put them into their pockets, even though the poor animals do scratch like a sitting hen. I did not want any bats. A sort of solemn feeling came over me as had many times before during the trip. "In the beginning God created the heaven and the earth"—even this Mammoth Cave; or, at least, he laid his plans so that the water might do the work. I did not feel like talking. The iron door swung back, and we passed out. The little cascade sparkles again in the moonlight. How different is the outer air! It seemed heavy and suffocating. The odors of the trees seemed strange and intense. I am told that people sometimes experience faintness as they pass out. Good-by, old Mammoth Cave. I am a wiser man after having formed your acquaintance, and may God grant that I am, at least in some respects, a better one.

Now, then, a word or two in regard to how all this came about. Perhaps many of you feel like saying with Huber, "Where 'gettie'?" Yes, indeed, "where 'gettie'?" Well, I will give you some of my opinions, gathered from what I saw and heard. Green River, of which I have told you, is quite a brisk-moving body of water, away down between two great hills, or mountains, only they are not hills or mountains, for there is no valley on the other side. The river has cut its way, as it were, through the rocky landscape. In fact, it is cutting its way deeper all the while. Somebody has said that it empties eventually into the Ohio River, with its freight of minerals in solution. Well, some time Green River was not down so deep in the earth. The rain water years ago fell on the hills of Kentucky as it does now. It ran into the valleys, and then ran into the ground. To escape, the water cut passages through the fissures of the rocks, and finally formed Green River. As the river cut its way down, the water settled in the hill to a lower level, and left its first channel high and dry. As this process went on for centuries, the water was continually cutting new water-courses, forming new subterranean rivers, as it were. At the same time the water was cutting away, it was, in other places, building up by precipitating these mineral substances. Now if you go back and read what I have described, keeping the above in mind, you will find the solution to many of these mysteries—Bacon Chamber, for instance. How does it come, however, that these stalactites and stalagmites, and chunks of bacon, and snowballs, and other things, are not now soluble in water? In fact, many of the specimens are more like flint or quartz. Well, see if I can help you by an illustration. If the water of

a spring ran over some cakes of tallow, it would not affect the tallow at all, nor would the tallow affect the water. Suppose, however, the water first ran through a body of ashes. Then it would be ready to wash away the tallow with great rapidity; and as it evaporated, soap would be left along its course. In this same way, many minerals are dissolved and held in solution, and again precipitated. There are said to be in the State of Kentucky 100,000 sink-holes, such as were so great a curiosity to me when I first saw them out of the car window. There are also many smaller caves. In Edmonson County alone we are told there are upward of 500, big and little. What a wonderful field for exploration, and what a wonderful place to study God through his works—yes, works that are going on even now!

In the beginning God created the heaven and the earth.

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

A. I. ROOT,
EDITOR AND PUBLISHER,
MEDINA, O.

TERMS: \$1.00 PER YEAR, POSTPAID.

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, JUNE 15, 1885.

And this is the condemnation, that light is come into the world, and men loved darkness rather than light, because their deeds were evil.—JOHN 3:19.

BEEWAX AT THE PRESENT DATE.

UNTIL further notice the best offer we can make on beeswax is 22c cash or 25c trade.

THE A B C OF CARP CULTURE.

WE are happy to say, that the above book is now in stock, and all orders have been filled some days.

BUSINESS AT THIS DATE, JUNE 15.

ALL orders are filled, and clerks are waiting for more, ready to pitch into them the minute they get their hands on them, if we may except orders including untested queens. But these are only a few days behind, and enough queens are in the apiary to fill all orders on our books as soon as said queens get to laying.

HONEY FROM THE HARD MAPLE.

WE notice that Bro. Jones, of the *Canadian Bee Journal*, suggests that hard maple yields as much, if not more, than fruit-blossoms. We admit this to have been the case this past spring, but we do not believe it is a common occurrence. During only two seasons have we noticed the hard maple yielding such a quantity. However, it will be an excellent idea to have strong colonies in good trim for this new source of honey.

HONEY-LABELS.

WE have just finished printing our new book containing specimens of all the different kinds of honey-labels now ordinarily in use, both in black and colors. Every possible pains has been taken to present to our friends the most attractive display

for their honey-packages. The book is 4x6 inches, and contains about 24 pages. Besides labels for honey, we also print letter-heads, envelopes, library numbers, etc. All interested in this particular line should not fail to send for one, which will be mailed to any address free.

A KIND WORD FROM OUR OLD FRIEND MR. LANGSTROTH.

WE are all rejoiced at the receipt of the following few lines on a postal card—especially the concluding part of it. Of course, we told friend L. that we would regard it as a privilege to send him a potato-book, or any other book, free of charge, if he is able to read it.

Please send the potato-book, and charge to my account. I am thankful to be able to inform you that I have recovered a very comfortable use of my limbs from the attack of paralysis last February, and that my general health is improving.
Oxford, Ohio, June 3, 1885. L. L. LANGSTROTH.

MAIL ROBBERY.

A MONTH ago, a mail-bag containing a large amount of our mails was stolen somewhere on the route. This mail-bag has recently been found, and many of the letters have been forwarded to us. The whole will reach us as soon as the U. S. detectives have got through with the letters. This will explain the reason of delays to several of our customers. Their letters were just about one month behind time when they came to us. We learn that our friend A. C. Nellis, of the Mohawk-Valley Seed Warehouse, has had a similar trouble, but a much more extensive one. It was caused by a clerk in the Canajoharie postoffice, who is now under arrest.

THE WIRE NETTING FOR POULTRY-YARDS.

WE have purchased over a thousand dollars' worth of this wire netting already, and have finally enough on hand to fill all orders promptly. The fabric is being used for a great variety of purposes besides confining poultry. It is a cheap, neat, and efficient protection for almost every thing that needs to be protected. It is well known that Irish junipers, when small, are often injured or killed by dogs or other animals. Roll up a piece of wire netting, set it over the tree, put four or six stakes inside, staple a band of netting to the stakes, and you have it. If you want to train climbing vines on your porches or elsewhere, a strip of netting makes the nicest trellis you can invent. It never rusts, and is unaffected by summer's heat or winter's storms. If you want to exhibit some nice goods, fruit, oranges, or berries, make a screen around in front of your fruit, with wire netting; and although it is full in sight, even meddlesome small boys are prevented from handling it. New uses come up for it every day. See advertisement on cover.

BEE-VEILS WITH GLASS IN FRONT OF THE EYES.

THIS matter has come up again, and our friend J. C. Capehart mails us a sample of a very neat one. The glass is quite thin, and slightly concave. It is very neatly attached to the mosquito netting that forms the body of the veil. Some of the friends may remember when the subject was up several years ago, that the matter was pretty thoroughly discussed. You can see better through a clean glass than you can through any sort of lace or netting; but unless you are very careful the glass will become soiled, and then you have to keep wiping it off as our elderly friends wipe their spectacles. If you get any honey on it, you would be apt to turn it to one side, and prefer to look through the netting.

Another thing, such a veil can not be handled as veils usually are, or the glass would be broken. If you are very neat and tidy in your habits, however, may be you will think the glass front is a very great improvement. Friend Capehart will mail you one per terms in his advertisement in last issue, if you wish to try it.

REDUCED RATES BY FREIGHT ON BEE-HIVES, EXTRACTED HONEY, AND IMPLEMENTS GENERALLY, USED IN THE APIARY.

At the Bee-keepers' Congress in New Orleans, the matter of freights was talked over pretty thoroughly; and as we had a railroad man among us, Mr. S. C. Boylston, General Freight Agent, of Charleston, S. C., I suggested that we instruct him to properly present the matter before the proper railroad officials. He has done so, and has accomplished enough, at least, so that he should have the thanks of every bee-man north or south. Honey in barrels or kegs can now be shipped as fifth-class freight, or at the same rate of classification as syrup and molasses. The rates on hives in the flat and set up are about the same that we had been obtaining from most of our large lines; but friend Boylston has succeeded in securing a general classification, so that, hereafter, railroad men need not say they do not know what rates ought to be charged for bee-hives, and so put them in as double first-class (that is the rate they charge for shipping looking-glasses), so as to be sure to get it high enough. Friend Boylston is a fair type of a real live Southerner, and he is just the man exactly for the place he fills. Friend B. can doubtless furnish printed leaflets containing this classification, which you are to get and submit to your own railroad agent, if he is not posted. The new classification took effect June 2, 1885. We will publish a letter from Mr. B., in the next issue.

WHO SHALL BEAR THE LOSS?

SUPPOSE A ships B ten pounds of bees, with a queen with each, and they arrive at their destination dead. In such a case, the usual way has been for A to send another lot, and so on, until he succeeds in getting the whole to the destination in good order. If A is so unskillful that he loses money badly before he gets through, he had better give up shipping bees and queens. But suppose, friends, after the first lot arrives at the destination dead, B says he does not want any more because it is so late in the season, or something of that kind. Shall he receive his money back, and leave A to shoulder the whole of the heavy loss? This question comes up almost every season, and I do not know that a decision has been made in regard to it. Of course, a good deal would depend on what A advertises to do. If he simply advertises to replace all lost in transit, I can not see why he should be asked to refund the money, unless he chooses to return a part of it, rather than to undertake further shipments; and my decision would be, that in no case should A be asked to return the full amount, shouldering the whole loss himself. Shipping bees and queens is necessarily a risky business; and in view of this I would caution new hands to beware about making their printed prices lower than they can stand, in case of such contingences as the one I have mentioned. Of course, A should be prepared to send more bees promptly as soon as he knows his first shipment was a failure. If he can not do this, he should discount on the prices in accordance with

the amount of time that elapses. Of course, the later in the season bees are sent, the less would be their value.

BEING IN HASTE TO SHIP GOODS BACK THAT DO NOT PLEASE YOU, BEFORE YOU HAVE HAD ORDERS TO DO SO.

THERE are few things in business that so vex and try my patience as this fashion that has, by some means or other, got hold of some of the friends. I suppose it is sometimes done because of ill humor in being disappointed; and things that are done in ill humor are seldom wisely done. Let me explain to you how it works. We do an immense trade in scales for bee-keepers, for instance, and may be furnish them at prices that have been hitherto unknown. We are enabled to do this by buying large shipments of the manufacturers; and then comes the question, "How small a margin can we work on?" Perhaps we could handle the goods with a margin of only 10 per cent, if we could be safe from losses in the way of goods injured in transit, mistakes in addresses, and other incidentals. To guard against defective goods being sent out, we make arrangements with the manufacturer that he is to make good all defects at his own expense; then when a complaint comes we direct the complaining party to ship it straight to the factory, and we send him another one from here. This all goes nicely unless our friend gets vexed in finding his scale defective, and ships it to us by express, without asking for orders in regard to its disposal. When it gets here by express the charges are more than the profit we make on half a dozen scales, and it has to be shipped again, may be to some of the Eastern States. What should he have done? Why, he should have written on a postal, "Mr. Root, this scale does not weigh right, and we can not fix it. What shall we do?" Our answer would have been almost equally brief, "Get it repaired if you can, and we will pay charges. If you can not conveniently, ship it to —, and notify us by return mail, and we will replace it at our own expense."

Sometimes goods are returned to us by express when the nature of the break makes them entirely worthless; and charges toward a dollar or such a matter have to be paid in express charges, or else the innocent express companies suffer. I have heard of shipping back *dead fruit-trees*, instead of informing the shipper that they had been delayed so long on the way that they were perfectly worthless. Have you any legal or moral right to burden one of your fellow-men in the shape of charges on any kind of goods before he has had an opportunity to even consent to your act of re-shipping? Has anybody any right to send any one any thing by express, unless he has been ordered to do so? If you pay charges to destination, that is another thing, to be sure; but even then I think it best to get permission before you ship the goods. It is a trouble and bother to us to have goods sent here that we do not want here, even if the charges are paid.

UP WITH ORDERS

I am up with spring orders, and can send queens by return mail. If you want untested Italian queens, reared from imported mothers, send \$1.00 for one; \$1.90 for two; \$5.00 for six; \$9.00 for 12.

THE ABC OF CARP CULTURE

JUST ISSUED.

A COMPLETE TREATISE Upon the Food Carp and its Culture.

INCLUDING PLANS AND SPECIFICATIONS, AND FULL-
EST INSTRUCTIONS FOR THE CONSTRUCTION OF
PONDS, AND EVERY THING PERTAINING TO THE
BUSINESS OF RAISING CARP FOR FOOD.

By MILTON P. PEIRCE,

Secretary of the American Carp Cultural Association.

*Illustrated by Many Fine Engravings,
With a Copious Index.*

PRICE 45 CTS.; BY MAIL, 50 CTS.

A. I. ROOT, MEDINA, OHIO.

WANTED.

Orders for Carniolan and Italian Queens and nu-
clei from best imported mothers. Send for Price
List to A. F. SHANNON,
B-Hld. SPRING HILL, DECATUR CO., IND.

I WILL SELL

Chaff hives all complete, with lower frames, for
\$2.50; in flat, \$1.50; 2-story Simplicity, complete,
\$1.25; in flat, 90c.

Comb Foundation, made from pure refined wax,
45c per lb. for heavy; 55c for light. Other supplies.
Send for price list. A. F. STAUFFER,
B-Hld. Sterling, Whiteside Co., Ill.

**DADANT'S FOUNDATION FACTORY, WHOLE-
SALE AND RETAIL.** See advertisement in
another column. B-Hld

I WILL SHIP FULL COLONIES.

OF Bees during July, Aug., and Sept., and guaran-
tee safe arrival by express. Pure Italians, \$7.50,
and hybrids \$8.50. These bees are in Simplicity
hives, and in good condition, with 9 frames and
straight combs in each hive. I leave out one
frame for more room. Ready to ship any day.
B-Hld H. M. MOYER, HILL CHURCH, BERKS CO., PA.

BEEES FOR SALE.

I will sell fifteen colonies of Italians and hybrids
in Root's chaff hives, all strong and in good condi-
tion, for \$6.00 per colony, on cars here. B-Hld

THOMAS HUNT, MAYNESVILLE, WARREN CO., OHIO.

Names of responsible parties will be inserted in
any of the following departments, at a uniform
price of 20 cents each insertion, or \$2.00 per year.

\$1.00 Queens.

Names inserted in this department the first time with-
out charge. After, 20c each insertion, or \$2.00 per year.

Those whose names appear below agree to furnish
Italian queens for \$1.00 each, under the following
conditions: No guarantee is to be assumed of purity,
or anything of the kind, only that the queen be reared
from a choice, pure mother, and had commenced
to lay when they were shipped. They also agree to
return the money at any time when customers be-
come impatient of such delay as may be unavoidable.

Bear in mind, that he who sends the best queens,
put up most neatly and most securely, will probably
receive the most orders. Special rates for warrant-
ed and tested queens, furnished on application to
any of the parties. Names with *, use an imported
queen-mother. If the queen arrives dead, notify us
and we will send you another. Probably none will
be sent for \$1.00 before July 1st, or after Nov. If
wanted sooner, or later, see rates in price list.

I will, after June 21, furnish untested queens from my choice imported queen-mother, for \$1.00 each. Nucleus with queen, \$3.00.

91tdb J. L. HYDE, POMFRET LANDING, CONN.

POTATO-BOXES

(TERRY'S).

These are made of basswood, lined with galvanized iron. The galvanized iron gives strength, and the basswood strength and lightness. These hold exactly a bushel when level full, and may be piled one on top of another. Although they are made especially for potatoes, they can be used for fruit, vegetables, picking up stones on the farm, and a thousand other purposes. When piled one above the other, they protect the contents from the sun and rain; and from their shape a great many more bushels can be set into a wagon than where baskets are used. They are also much more substantial than baskets.

Price 25c each; 10, \$2.25; 100, \$20.00. In the flat, including nails and galvanized iron, \$1.75 for 10; 100, \$16.50; 1000, \$150. **A. T. ROOT, Medina, O.**

Price 25c each; 10, \$2.25; 100, \$20.00. In the flat, including nails and galvanized iron, \$1.75 for 10; 100, \$16.50; 1000, \$150. **A. T. ROOT, Medina, O.**

J. P. Moore is again making a specialty of rearing **FINE WARRANTED ITALIAN QUEENS** from his choice business strains, which never fail to bring joy to his customers. The following is a sample extract:

I never had as handsome bees and good box-honey workers as I have from you. **J. V. CALDWELL.**
Cambridge, Ill., Feb. 10, 1885.

Prices: Single (warranted) queen, \$1.00; 6 for \$5.00. 13d Address **J. P. MOORE, MORGAN, PENDLETON CO., KY.**

75 Strong Colonies of ITALIAN BEES FOR SALE.

100 THREE-FRAME NUCLEI, full of bees and brood, with tested queen, \$3.00; with untested queen, \$2.50. "The bees rec'd from you are the best workers I have ever had." **L. M. MCKE, Columbus, O.**

J. A. BUCHANAN,
13d HOLLIDAY'S COVE, HANCOCK CO., W. VA.

THE KIND OF BEES YOU NEED.

If you want bees for business, get those that will work on red clover. Not a colony of this strain lost in wintering since they originated. Circular free.

OLD TYPE FOR SALE.

We have still on hand 56 lbs. of our old nonpareil type for sale. For a sample of it, see any number of GLEANINGS previous to May 15, 1884. Also 17 lbs. of Italic, if desired. As it is all packed, we can not divide either lot. The Roman includes 5 lbs. and over of "logotypes;" that is, the words *the*, *and*, *that*, *ing*, *tion*, etc., are made all on one body, thus facilitating composition. We offer the lot at 15 cts. per lb.

A. I. ROOT, Medina, Ohio.

SOMETHING NEW.

J. H. JOHNSON, Middaugh, Northton Co., Pa.

JOB LOT OF WIRE CLOTH AT GREATLY REDUCED PRICES.

Such a brisk demand has sprung up for this, and our customers seem to be so much pleased with the goods, we have succeeded in getting another still larger lot, of one of the largest manufacturers of wire cloth in the world. Please bear in mind that the only way in which we can afford to sell it at the very low price of 1½ cts. per sq. ft. is by selling the entire piece just as it is put up. We have now in stock the following pieces. As fast as it is sold, each piece is crossed out, and the next issue will show what remains.

SOME OF THE USES TO WHICH THIS WIRE CLOTH CAN BE APPLIED.

This wire cloth is first quality in every respect, and is just the thing for covering doors and windows, to keep out flies, for covering bee-hives and cages for shipping bees, making sieves for sifting seeds, etc.

Number of Square Feet contained in each Roll respectively.

10	3 3 rolls of 75, 72, 70 s. f.
12	2 2 rolls, 100 s. f. each.

12-13d

GEORGE W. BAKER, MILTON, WAYNE CO., IND.

HONEY COLUMN.

CITY MARKETS.

CLEVELAND.—*Honey.*—There is no change in the honey market. The prices are nominally unchanged, 14¢45, but we have no transactions to report; in fact, we do not look for any demand until after the strawberry season, when there usually springs up a demand.
A. C. KENDEL.

June 20, 1885. 115 Ontario St., Cleveland, Ohio.

BOSTON.—*Honey.* 2-lb. sections, best white, 14; 1-lb. sections, best white, 15; extracted, 7¢9c. Trade, of course, is very slow on honey, but we can't expect any thing better this season of the year.

Bee-swar. none on hand. Sale very slow.

June 22, 1885. BLAKE & RIPLEY,
57 Chatham St., Boston, Mass.

CHICAGO.—*Honey.*—Very little doing in the honey line at present. Market may be said to be very dull; prices unchanged from last quotations.

Bee-swar. 23¢25c; quiet.

June 20, 1885. R. A. BURNETT,
161 So. Water St., Chicago, Ill.

NEW YORK.—*Honey.*—There is no change in prices of honey from last issue. *Bee-swar.* lower. Prime yellow sells at 26¢29c., as to quality and quantity.

June 13, 1885. McCALL & HILDRETH BROS.,
34 Hudson Street, corner Duane St., New York.

CINCINNATI.—*Honey.*—There is no change whatever in the market for honey, which is without life for some time. We have a good class of regular customers who use considerable honey, while outsiders can hardly be induced to purchase. We quote extracted honey at 41¢@8c, and comb honey at 9¢12c on arrival. *Bee-swar.*—Demand is good for beeswax, which brings 23¢@28c on arrival for good yellow.

S. E. Cor. Freeman and Central Avenues,
June 20, 1885. Cincinnati, Ohio.

ST. LOUIS.—*Honey.*—Our market continues very dull. Extracted Southern, in bbls., held at 5c; half-bbls., 6c. Comb honey, no demand; nominal, 8 to 12c. *Bee-swar.*—There is very little demand. Stock increasing; last sales at 23c, likely to go lower.

W. T. ANDERSON & Co.,
June 22, 1885. 104 N. Third St., St. Louis, Mo.

MILWAUKEE.—*Honey.*—This market is without any interesting features to note regarding honey. There is very little comb, and the demand is almost nothing from first hands, and values nominal. Extracted in good supply, considering the limited demand for it. Quotations nominal; viz., 1-lb. sections, white, 12¢12½c. Extracted, in pails and kegs, 7¢@8c. *Bee-swar.*—Slow, and demand light. 25¢@28c.

June 22, 1885. A. V. BISHOP,
142 West Water St., Milwaukee, Wis.

NEW YORK.—*Honey.*—Nothing doing in comb honey. Quite a lot of old stock in market yet, but we believe it will be disposed of before new comb honey comes in. We make no change in prices since our last. New Southern extracted honey is coming in freely, and selling at from 55¢@60c. per gal. in lots.

Bee-swar plenty, demand limited, and prices ranging from 25¢@27c. for prime quality.

June 22, 1885. THURBER, WHYLAND & Co.,
Reade & Hudson Sts. New York.

CIRCULARS RECEIVED.

J. W. Clark, Clarksburg, Mo., sends us an 8-page list of supplies generally.

J. P. Connell, Hillsboro, Texas, sends us a 4-page list of bees and queens.

E. W. Geer, St. Mary's, Mo., sends us a 4-page list of bees, hives, and supplies generally.

Wm. Little, Marissa, Ill., sends us a 6-page price list of bees and queens, very nicely printed.

George M. Gray, Medina, O., has just handed us his new specimen-book of plain and colored labels for honey-cans, and other purposes. In this book, which contains about 40 pages, Friend George has given us the best production of his hand and brain, both of which are above mediocrity in this line of work. It will pay you to send and get a copy, which will be mailed free, to all contemplating business.

LET ME HELP YOU.

I will sell, to all wishing to buy during July, August, and September, pure Italians. One hive for \$6.00; five or more for \$5.50 each.

Hybrids, one for \$5.00; five or more for \$4.50 each.

Blacks, one for \$4.50; five and more, \$4.00 each.

All 10-frame, 2-story, new Langstroth hives. Safe arrival guaranteed.

G. W. ALBRECHT,
13-14-15d Dundas, Calumet Co., Wis.

SAFE Introduction. After July 1st, for from imported mother, \$1.10, or safe arrival only guaranteed, shipped in the *Safe Introducing* cage for \$1.00. Send for our new catalogue. You will learn something new. See ad. in May GLEANINGS. S. A. DYKE & CO.,
13-14-15d Pomcroy, Meigs Co., Ohio.

Italian Queens.

Untested, each	 \$1 00, or six for	 \$5 00
Tested,	 2 00,	 11 00
Two-frame nuclei, with tested queen,	 4 00	
..... untested	 3 00	

My queens are from imported or home-bred Italian mothers; the same strain has averaged for the last four years from 30 to 236 lbs. of honey per colony. Try them. They will please you. Safe arrival guaranteed. Comb Foundation, brood, 40c; light, 50c. Address

13-14d J. J. HURLBERT, Lyndon, Ill.

150 CHOICE CELERY PLANTS

by mail postpaid, for \$1.00; 350 for \$2.00; 1000, by express, \$2.50. Reduction on large lots. Please address A. T. COOK, CLINTON HOLLOW, DUTCHESS CO., N. Y.

A. I. ROOT SAYS:

"I have examined your Automatic Honey-Extractor and am well pleased with it. It is well made, and the reversing device does you much credit."

For full particulars, address 13d

G. W. Stanley & Bro., Wyoming, N. Y.

I WILL SELL

From June 15, until Sept. 15, good Italian bees at \$1.25 per pound. Nucleus colonies, 3 frames, L. size, at \$3.25 each. Dollar queens to accompany the above, \$1.00 extra. All my queens are reared from imported stock. Safe arrival and satisfaction guaranteed.

J. M. YOUNG,
13d Rock Bluffs, Cass Co., Neb.

CARNIOLAN QUEENS.

I have just Received a Queen from Carniola, and will raise a few Queens of this Stock in my Italian Apiary at once. The Carniolans are Handsome, and Undoubtedly the Gentlest Bees known. I will have about One Hundred Queens ready to Mail about July 20. Safe arrival Guaranteed, at One Dollar Each.

13d JAMES H. MORRISON,
OXFORD, CHESTER CO., PA.

BEES AND QUEENS ON HAND.

Up with orders to date. 1 pound bees, one comb brood, and "\$" queen, all for \$2.50. Fdn., 45c. to 55c. June 25, '85. OLIVER FOSTER, Mt. Vernon, Linn Co., Ia.

WANTED. A competent and reliable man wants a position in an apiary; is also a first-class carpenter. Best of references given and required. Address
F. C. ELISON,
13d SMITHPORT, MCKEAN CO., PA.

Vol. XIII.

JULY 1, 1885.

No. 13.

TERMS: \$1.00 PER ANNUM, IN ADVANCE; 2 Copies for \$1.00; 3 for \$2.50; 5 for \$4.00; 10 or more, 75 cts. each. Single Number, 10 cts. Additions to clubs may be made at club rates. Above are all to be sent to ONE POSTOFFICE.

Established in 1873.

PUBLISHED SEMI-MONTHLY BY
A. I. ROOT, MEDINA, OHIO.

Clubs to different postoffices, NOT LESS than 90 cts. each. Sent postpaid, in the U. S. and Canada. To all other countries of the Universal Postal Union, 10c per year extra. To all countries NOT of the U. P. U., 42c per year extra.

NOTES FROM THE BANNER APIARY.

NO. 67.

SEPARATORS AND "FEEDING BACK."

LAST April we received a letter from which we make the following extract:

In GLEANINGS for April 1st you say: "I have been quite enthusiastic in explaining how to dispense with separators, and have shown by my *works* that first-class honey *can* be raised without them." This called to my mind a statement made to me just after the adjournment of the convention last December at Lansing. It was made by some friend whose name I did not retain, but it rather threw a damper upon my enthusiasm. The statement was, that he had seen the man who bought your honey crop of 1883, and had, I think, also seen the honey, and that some of it was *badly* "bulged." I have also heard this story from other sources, and have been afraid to *try* to get along without separators. I hope this report may not be true; but if it is, some of us would be glad to hear the whole facts in the case.

We replied, in substance, as follows:

Yes, my friend, it is *true*, that some of that honey was "bulged." When the convention was held in Flint, some of the members went and saw the honey, and, as you say, "we have heard this story from other sources." The "whole facts in the case" are, that we were that year experimenting in "feeding back," and the result was quite a number of "bulged" sections. The honey that we raised without "feeding back" is as straight as could be desired; and so few bee-keepers are experimenting in feeding back that we have never thought it worth while to publicly explain.

It seems to be the fashion nowadays among some apicultural writers, to wish to "put on record" some of their prophecies. If, in after years, things turn out differently from what is expected, the predictions will have been forgotten; if Mr. Prediction guesses right, he can then revel in a triumphant "I told you so." Well, here goes: "If 'feeding back'

is ever made a success, separators will be needed." When bees take their food from a feeder, they behave differently than when they collect it from the flowers. When feeding back, bees build comb in every nook and cranny. They not only "bulge" the combs in the good old-fashioned way, but they even build little mounds, or projections, upon the surface of the combs; do it, too, in such a reckless, unreasonable, fantastic way as to often cause a provoked smile. All colonies do not behave in this way, but we can never tell what to expect of a colony until we give it a trial. Feeding back is as much an unsolved problem as "wintering." There are a great many ifs, ands, and buts yet to be learned.

TOP VERSUS SIDE STORING.

We have just been reading Mr. Doolittle's article on page 377, and the item of Mr. Faris on page 313, and it seems to me that this subject should have been discussed under a different heading. It is *not* a question of wide frames vs. cases, but one of top vs. side storing. Wide frames are often used in the top-storing, tiering-up method, while some bee-keepers use a case that can be used not only on top of the brood-nest, but at its side, or even in its center; hence, in our opinion, there is no point to the assertion of Mr. Doolittle, that "those who have decided wide frames are not the things to use will never fully realize the possibilities of bee-keeping." There is no question but that wide frames possess some advantages over cases, and *vice versa*. Were we to adopt separators we should certainly use wide frames one tier of sections high, and tin is the stuff for separators. Mr. Doolittle contracts the brood-nest, and secures excellent results; *we* do the same with like results; but instead of putting sections in the space left after contraction, we simply annih-

late this space, or, rather, transfer it to the surplus apartment *above* the brood-nest. It is the experience of some bee-keepers, that by this method just as much honey will be secured with less labor.

W. Z. HUTCHINSON, 50-72.

Rogersville, > Genesee Co., Mich.

Friend H., I find about the same thing in feeding back that you mention, although, as you say, some colonies will do better than others. Another thing about the feeding-back business is, that I have never seen any feeder yet that would induce bees to take as many pounds of honey day after day as they frequently gather from the fields during clover and basswood bloom. I do not know what the reason is, but they will start in at first and take perhaps ten or fifteen pounds of honey in 24 hours. The next day they will seem to be a little tired out, and won't do so well, and every day succeeding they will be a little "lazier" still. I have fed a single colony as much as 100 lbs., perhaps, to get it stored in sections, but it took a much longer time to do it than where 100 lbs. were gathered from the fields. Unless the work is done when no honey is coming in, you may be the loser, for the colonies that are fussing with feeders will neglect and lose any thing that may be had from natural stores.

REDUCTION IN FREIGHT ON BEE-KEEPERS' SUPPLIES.

FRIEND BOYLSTON TELLS US WHAT HE HAS ACCOMPLISHED, AND HOW HE DID IT.

MR. EDITOR:—I went to Atlanta on Wednesday last, and appeared before the Rate Committee of the Southern Railway and Steamship Association. Mr. Virgil Powers, Gen'l Commissioner, was in the chair, and the following members of the committee were present: Mr. Sol. Haas, Traffic Manager of Associated Railways of the Carolinas and Virginia, Richmond, Va.

Mr. Jos. M. Brown, G. F. Agt. of the Western & Atlantic R. R., Atlanta, Ga.

Mr. E. R. Dorsey, G. F. Agt. of Ga. R. R., Augusta, Ga.

Mr. J. R. Ogden, G. F. Agt. of E. T., V. & Ga. R. R., Knoxville, Tenn.

Mr. Geo. R. Knox, G. F. Agt. Nashville & Chattanooga R. R., Nashville, Tenn.

Mr. S. B. Pickens, G. F. Agt. So. Ca. R. R., Charleston, S. C.

Mr. G. A. Whitehead, G. F. Agt. Central R. R. of Ga., Savannah, Ga.

Mr. J. M. Culp, G. F. Agt. Louisville & Nashville R. R., Louisville, Ky.

Mr. C. A. Sindall, Secretary S. R. & S. S. Ass'n, Atlanta, Ga., and quite a number of gentlemen from the different railways south of the Ohio, and from New York, who had come to attend to various railroad matters. I was personally acquainted with each and every one of them, and the room was full.

The first question taken up was proposed changes in the classification, and this occupied about two hours. Just as they were about to close I preferred my request—had my classification of bee-products and bee-keepers' supplies all ready, and handed it in. The nature of it had hardly been an-

nounced before it was echoed by a general chorus of laughter, and a serious attempt to ridicule it was made. One member who doubted his ears wanted to know if he really heard aright, and whether I was really in earnest in making the request. I at once frowned down all attempts at levity, and said I appeared before them by direction of the Congress of Bee-keepers which had recently met at New Orleans, and, as one of them, demanded that our requests should receive that same earnest and respectful hearing as was accorded to a representative of any other 300,000 Americans who were doing business in the land; and I then stated our wants, the magnitude of the business, and the growing importance of the industry. Finally on motion of Mr. Haas, seconded by Col. Dorsey, my proposition was carried as a whole, and I got all I asked for. Does it suit you? If not, let me know, and I will do all I can to better it.

Bees in hives—owner's risk, 1st class; carrier's risk, twice 1st class.

Bee-hives, empty, set up, 1st class.

Bee-hives, knocked down, crated, class A.

Bee-hives, knocked down, car load, 5c less than class A.

Bee-smokers, boxed, 1st class.

Honey in bbls. or kegs, owner's risk, 6th class; carrier's risk, 5th class.

Honey in glass or tin, packed, owner's risk, 3d class; carrier's risk, 1st class.

Honey in comb, boxed, owner's risk, 3d class; carrier's risk, 1st class.

Honey-extractors, crated, carrier's risk, 1st class.

Honey section boxes and frames, crated or boxed, owner's risk, 4th class; carrier's risk, 3d class.

Wax-extractors, crated, 1st class.

Wax comb foundation, 2d class.

If you will notice by examination of the classification I send, honey has been placed same as syrup; bee-hives set up, same as empty boxes; bee-hives knocked down, same as barrel-staves or box material in bundles; section boxes and frames, same as wooden butter-plates, etc.

The classification applies between all points named in the rate-sheets I send you, and is the one in general use for local shipments on nearly every road south of the Ohio and east of the Mississippi, and on all the coastwise steamers and on all the river boats in Florida (I hope friend Hart is happy).

This is a good start; and if the bee-associations in the North and West will only follow it up they will succeed likewise. I will send you fifty of these new classifications as soon as printed, that you may put them in the hands of bee-societies, to be used as an example for your neighboring roads, provided always that you need them, and that you approve of the action I have taken.

If you think of any thing which has been omitted, let me know and I will do all in my power to make it more perfect.

S. C. BOYLSTON,

Gen'l F. & P. Agent, C. & S. R. R. Co.

Charleston, S. C., June 4, 1885.

Friend B., you have done your part excellently. I should say; and as I said in my editorial last month, I think the bee-keepers of the land owe you a vote of thanks. The rates on bees in hives are lower than I expected; but they are not often sent as freight, so far as I know, although we once sent one shipment of a considerable size by freight, and it went all right. Your rates

are about the same that we obtain on most of our roads here in Ohio; but when we strike other roads in different States, a great many times they will charge first class or double first, when it ought to have been third class, and make, as an excuse for it, that there is no "rating."

DEATH FROM EATING POISONED HONEY.

IS IT FACT OR FICTION?

PLEASE read the inclosed item, which was telegraphed all over the country, in regard to the so-called honey-poisoning by eating honey impregnated with gelsemium from yellow jessamine. It is said to have caused three or more deaths. Do you think it possible? Suppose we call on Prof. Cook, or some able botanist, for a definition of gelsemium of yellow jessamine, and what latitude the plant is chiefly confined to. Such reports are damaging to the honey trade, to say the least; and being interested to a considerable extent in that line I should like to have such a statement as that refuted if possible.

Nashville, Tenn., June 11, 1885.

H. B. GEER.

WHOLESALE POISONING; TERRIBLE RESULTS OF EATING HONEY IN A SOUTH-CAROLINA COMMUNITY.

BRANCHVILLE, S. C., June 6.—Mrs. Jacob Dukes gave a negro servant some honey, which the servant gave to her four sons for dinner. Almost as soon as they had eaten it they complained of blindness and dizziness. In 10 minutes one had died and within half an hour two more had died. By this time the report of the affair had reached Mrs. Dukes. Her entire family were just experiencing the first symptoms of the trouble from which the negroes had died. Dr. Ott was sent for, and by applying antidotes the family was saved after great suffering. Half a dozen other families who had been supplied with this honey were similarly affected, and it was only by energetic work that there were not 20 deaths instead of three. This event explains two other deaths which took place in this neighborhood on Monday. An examination of the honey showed that it was impregnated with gelsemium from yellow jessamine, which has been the cause of many deaths heretofore of persons eating wild honey.

On receipt of the above I mailed it to Prof. Cook, as our correspondent has suggested, and below we have his reply:

Dear Mr. Editor:—I was much interested in reading the article from Branchville, S. C., and also the letter from H. B. Geer, in reference to poison honey. If you will refer to the *American Bee Journal*, 1881, p. 22, you will see that my attention was called at that time to a somewhat similar case, which, however, was less serious in its results. Possibly the outcome might have been quite as terrible had not a good physician been at hand. To summarize that case: Mr. C., a New-York bee-keeper, sent some honey to some friends in New York city, who were made seriously ill by eating it. The honey was sharp, like pepper, produced coughing, and soon severe nausea, violent vomiting, loss of vision, and a chill. A physician being at hand gave an emetic, and followed this by whisky. Soon the persons were all relieved. I secured some of this honey, and proved the stinging taste and the throat irritation; but being averse to whisky remedies, I carried the experiment no further. Mr. C. could easily select out all this honey by the sharp peppery taste. He said it was certainly gathered before July 10th. I found this honey was also bitter, and that heating

did not volatilize either the bitter or sharp properties. In the article referred to, as also in my Manual, p. 285, I give other cases of this exceptional honey poison, and refer to some common American plants which are supposed to be the source of such honey. As before stated, it seems to me very doubtful if these plants are the source of poisonous honey. The plants are common and abundant: the poisonous honey, rare and very exceptional. I think the same is true of yellow jessamine (*Gelsemium Sempervirens*). It is a common and much-prized honey-plant of Virginia, and States south of that; and were its nectar secretions poisonous, we should have learned the fact years ago. Thus while I can say with considerable assurance what the poison is not, I am at a total loss to say what it is. From the experience of the past, however, I think we have no reason to fear any serious trouble from this case, or the report of it. Any cases, so sporadic, never have any special weight or influence.

Let me add to the within, that the *Gelsemium* of therapeutics is an extract from the flowers, leaves, and roots. The tincture is said to induce stupor. It is used as a nerve and arterial sedative, and in large doses is a poison. That this was found in the honey, if true (possibly the whole report is a sensational canard from some unscrupulous reporter) was no fault of the bees, but of some one who had malice in his heart. The nectar which plants secrete does not partake of the qualities of the tissues.

A. J. COOK.

Agricultural College, Mich., June 20, 1885.

Friend Cook, I think you have struck the root of the matter in your concluding words. Upon first reading it, I was impressed with the idea that it might be a newspaper canard, something about like the one about all the liquid honey in the market being made from sour apple-skins, etc. Now, then, if we have a subscriber living near Branchville, S. C., I will pay him for his trouble for investigating in regard to the matter, and giving us the truth of it. We want the truth, no matter where it hits; and if there is not any truth in it we want to know that, no matter what it costs to get at the truth. We will mail the inclosed slip to the postmaster, and ask him if he can give us any information in regard to it. Meanwhile let us get at what other facts we can.

MRS. HARRISON AND SOME OF HER TROUBLES.

YES, TROUBLES EVEN DURING THE MONTH OF JUNE.

IF frames of eggs and larvæ are frequently removed from a colony, will it cause the queen to be superseded? I have sometimes thought it did. I have used all available means to build up my bees this spring; but to-day I have been trying to see how many I could kill. Inconsistent, is it? I have come to the conclusion that there was a score or two of bees that spent their time in watching around the kitchen-door to sting some person, and at last forbearance ceased to be a virtue. Armed with a palm-leaf fan, and a large dishpan with about two inches of soap-suds, I sallied forth to conquer. In a short time I had more than a score in the suds. These bees all looked alike, were yellow-banded, but had black, sharp-pointed tails. I do not believe those bees ever went in

search of honey, but were those dyspeptic kind father Langstroth speaks of in his book.

White clover is now (June 18th) blooming everywhere, but as yet is yielding little or no honey. Bees so far have made only a living. There is very little swarming, and the queen-cells are very diminutive—mere excuses for royal cradles. There has been a good deal of cool rainy weather, and the fields are white with clover; but on chewing the heads, they lack sweetness. The nights are cool, with very abundant dews, and bees are not seen on the clover until afternoon.

We have some spider lilies that have been transplanted from the woods, and bees work upon them daily; we notice that they are favorites with the bees every year. The locust yields honey in this locality this year. Mrs. L. HARRISON.

Peoria, Ill.

My friend, it is a fact that colonies are very much crippled by taking eggs and larva when they are too weak to spare them; and it is such weak and crippled colonies that seem to be up to such tricks as balling and superseding queens, right when they ought to be gathering honey.—I have sometimes thought, with yourself, that the bees that buzz about and sting, or pester a body even if they do not sting, are a sort of quarrelsome set, that are not of much use any way. My plan is to knock them down with a comb-guide; and after knocking down two or three I have secured a little peace. It does seem sometimes as if it were only about half a dozen bees in an apiary of a hundred colonies that annoy and worry one. It is rather bad business, however, to be seen killing your own bees. — The lack of honey in the clover is caused by the abundant rains which I suppose you are having as well as ourselves. When there comes a lull in this wet weather, however, I think you will find the honey begins to pour out from the clover to your full satisfaction. It usually takes half a day, and sometimes a whole day, after a drenching rain, for the clover to begin to secrete honey again.

BEE BOTANY,

OR, HONEY-PLANTS TO BE NAMED.

I INCLOSE a plant which grows plentifully here on wild prairie land which has been closely pastured, and on which the bees work freely, seeming to prefer it to dandelion, which is almost the only other honey-plant in bloom here at present. Can you tell me its name? I send a plant in bloom, and a stalk which has gone to seed, both of the natural size. BURDETT HASSETT.

Howard Center, Ia., May 22, 1885.

Prof. Devol replies:—

EVERLASTING.

The specimen of plant from Burdett Hasset is *Antennaria plantaginifolia*, Br., commonly called Everlasting, or Mouse-ear, a small plant 4 to 8 inches high, covered with whitish down, and bearing fadless heads of white and purplish flowers. Found mostly on knolls and side hills, on poor soil, in thinly wooded places. W. S. DEVOL.

I inclose in this letter a twig from a bush that grows about 6 or 8 ft. in height, and is covered with bees during the entire period of bloom (about three

weeks). This morning I found on a single bush 15 or 20 bumble-bees and 20 or 25 honey-bees, from which I think it must yield a good deal of honey.

Traer, Ia., May 26, 1885.

A. D. MCKAY.

Prof. Devol says of this:—

This is a specimen of *Lonicera ciliata*, Muhl. (Fly Honeysuckle), a well-known honey-plant found in woods, and blooming in May and June. It grows 3 or 4 to 5 ft. high, and when in bloom is covered with its pretty straw-colored flowers. W. S. DEVOL.

Columbus, O., June 22, 1885.

KEEPING THE GRASS DOWN AROUND BEE-HIVES.

ALSO SOMETHING ABOUT LAWN-MOWERS.

ISN'T it true, that a neatly kept lawn is evidence of an intelligent and progressive spirit possessed by the owner? A lazy and shiftless man seldom has any lawn at all. Many whose occupation keeps them indoors a great part of the day, derive health and enjoyment in taking care of a lawn, even though it be just a little one. And what makes life pleasanter than to see pleasant homes as we happen to pass along our country roads or village streets? Where you see a handsome lawn outside, you will almost always find the magazines and progressive journals of the day inside. One impediment in the way of these handsome lawns is the expense of a lawn-mower; and as we have spent some little time in looking the matter up, and trying the different kinds, especially those adapted to mowing around bee-hives, I thought I would tell you the result of it. The one pictured below

seems to please us best of all for working in the apiary; and another thing that pleases me is, that it costs only \$6.50. Even at this low price we like it better than some that cost twice as much. It does not make a very wide cut, it is true; but it runs so easily that the children can do the work. Its simplicity is an advantage in the apiary, for it will run up close to the entrances, and it will cut weeds and grass of a considerable height without difficulty.

Friend Fradenburg, as you may remember, prefers rabbits to lawn-mowers; but the rabbits might mow down something you don't want mowed down. We can furnish them promptly at the price named. As the machine weighs but 50 lbs., it will probably go cheaper by freight.

BUSINESS MEN AND BUSINESS METHODS.

MRS. CHADDOCK GIVES US AN ENERGETIC STIRRING-UP IN REGARD TO PROMPTNESS.

ON page 259 of April 15th GLEANINGS is an advertisement, that reads as follows: "Bees by the pound. From April 20 to May 20, \$1.00. Dollar queens to go with bees as above, \$1.00 each" (see advertisements). Brother Phillips and myself sent, on the 20th day of April, for four 1-lb. packages of bees with a dollar queen in each package; sent him the money, \$8.00, and then waited for the bees to come. We live five miles from town; and after a week had passed we began to haunt the postoffice and express office to find out about those "Tennessee bees." We took it by turns. I went in one day, and Brother Phillips would go the next; and time wore on without hearing a word from them till yesterday, the 8th of May. Then we got a letter from Mr. Gates, saying he can not send us four packages with a queen in each, but can send us two 3-lb. packages with 2 (or is it a 3?) queens; or, if we prefer, he will return the money, if we will send stamps for the registry fee.

Now, this I call business with a vengeance. Keep our money this long, and tell us he *can not* live up to his agreement, but will do something else—and, crowning stroke of all, make us pay registry fees both ways on the money, when his not doing as he agreed to has probably cost us dollars instead of cents.

I sent to you once for five "dollar" queens; I sent the order on Monday morning, and the queens came to the postoffice here on Wednesday evening, just like throwing a ball to you and you tossing it back again; and yet people complain that they have queens to sell, and no one will buy them. Perhaps they wait too long, and then offer to do some other thing.

I used to raise early vegetables for market—peas, potatoes, beans, cabbage, lettuce, radishes, strawberries, and other small fruits; and if I promised to furnish a man with berries on a certain day *Lal-weys did it*, even if I had to go out among the neighbors and buy them up. One time, I remember, I was selling strawberries on a certain cold Saturday. Mr. Chaddock was with me (generally I went alone); and while I was in a store delivering berries he sold all that were left, and just then a man came up and said I had promised him a gallon for Sunday, and I went into the store and bought back a gallon, paying ten cents more on the gallon than I would get of him; and I would do it in any business that I expected to carry on. My motto always was, *perfect satisfaction*.

Another time I engaged ten bushels of early potatoes, at one dollar per bushel, in a little town four miles away, and they nearly all agreed to take them, on condition that I would bring them in on the morning of the 4th of July, as there was to be a celebration there that day, and they all expected to have company, and they wanted new potatoes for dinner. I promised to take them, and thought it would be easy enough to fill the promise, as we fully expected to go to the celebration; but Mr. Chaddock had a field of wheat that was spoiling to be cut, and he found that he could get help, and he would not go to the celebration, and of course, I had to be at home to cook for the ten men. The hired girl had been promised her "liberty" on that

day, and that promise must be kept. Well, the hired girl and I dug the potatoes late the evening before, and I got up at two o'clock and ate a cold snatch while Mr. Chaddock got the team ready, and I was in Ipava just as the sun was rising and the merry bells were ringing in the "glorious Fourth."

I delivered the potatoes (half a bushel at each house), and got home at 8 o'clock; in plenty of time for the hired girl to start for the celebration with her beau, and I had ten dollars in my pocket to pay for my work. The next week, potatoes were a drug at 25 cts. a bushel. The early bird catches the worm.

MAHALA B. CHADDOCK.

Vermont, Ill.

A little more charity, my good friend Mrs. C. Friend Gates is one of the best men we have, and I think the trouble comes (or I suppose there is not very much trouble) from the different ideas you and friend Gates seem to have as to what is straight business and what is not, because you both look at it from a different standpoint. There are quite a few of the brethren whom I suspect would feel pretty glad if they could get their money back by paying the registry fee. I wonder if I can be enough of an outsider to take an unbiased view of this whole transaction. You are both good friends of mine, and for the life of me I can not tell which of you I like better, therefore I am sorry to see you have even small differences. Friend Gates does a large business in shipping bees; and unless he has quite a little help and a good deal of capital, he is liable to have more orders than he can manage. Now, it is no profit to him to get money and send it back again; in fact, he has all the trouble and correspondence, and not a cent profit. The notice in GLEANINGS of those who have untested queens and bees for sale reads: "They also agree to return the money at any time when customers become impatient of such delay as may be unavoidable." Now, friend Gates naturally decided that, under such circumstances, the sender ought to pay for the return registry fee; and although I can not quite agree with him, I can not see that he is so very unreasonable. I need not state the case from your point of view, for you have stated it pretty well yourself. A great many of these things can be made perfectly easy of adjustment by having an agreement beforehand. Suppose friend Gates say in his price list, "When my customers become impatient of unavoidable delays, I will return their money, providing they pay the return registry fee." This would have made it all right. Again, you see he agrees to fill the order, providing you will permit him to substitute bees for queens, because he is, like the rest of us, short of queens just now.

I am much obliged to you for the commendatory notice you give us; but, my good friend, we do not always send a queen right back, like "throwing a ball and tossing it back again." I wish we did, and I do not know any way we can advertise our business so well as to have queens enough ahead so we can always do this. This present season, in spite of all we could do, we have been short of queens, and some of the brethren (may be some of the sisters too) feel a little bitter toward me even yet, I suspect.

Your little story about the way you kept your promise given to each of your patrons is a good point; and if you have done that right straight through life, I wonder that you have not built up a big business. It is true, my friend, that a big business can be built up in almost any thing by letting the world know that you are prompt and reliable; yes, you can get more than the market price for every thing you want to sell, if you make your name "gilt edge." Your illustration about the importance of having your produce in market promptly, hits the point exactly; and I wish we could make this matter catching, like the measles and smallpox. Why, it is almost a matter of life and death; and promptness not only makes a man valuable here in this world, but it fits him for a better world after this one is finished.

Now, lest any one should get a little prejudiced against friend Gates in this matter, from what I have allowed you to say about him, I want to say he is one of the best and most reliable men that I know of; and I should not be very much afraid to say that every transaction he does not make satisfactory I would; and as he works on a small margin (he sells bees and queens a "good bit" cheaper than we do, you know), may be one of his business rules will be that his patrons must stand the expense of sending the money back, when orders come so thick he can't fill them all.

THE SIMPLICITY HIVE.

THE STAND IT IS NOW TAKING IN BEE CULTURE.

I THINK I am safe in saying, that there are now more Simplicity hives in use than any other one kind in the world. I do not mean to say that we have made them all, by any means, but that there are more hives made on this principle than any other. When I started out (nearly fifteen years ago) to make them, the idea I had in mind was something like this: It seemed to me there was a great need for some simple form of hive that could be made of a few simple pieces; and these pieces were to be so made that they could be combined so as to give a hive of any capacity, from a nucleus for queen-rearing up to a hive capable of containing the entire progeny of *any* queen. The hive was to be made of only two pieces—a body and a cover. When I use the word *hive*, I mean the outer shell, or covering, without reference to the inside furniture. That we might get along with these two pieces, and no more, I decided that the cover and bottom-board should be exactly alike, and interchangeable. Now, the plan was (and is) to have these two simple pieces made by such accurate gauges that they would always work together, no matter where or by whom the bodies and covers were made. To accomplish this, the well-known iron gauge-frames were devised, and are still used. When anybody sets up a bee-hive shop, if he gets one of these gauge-frames made accurately, to start with, he can be sure that the hives he makes will work interchangeably with the hives made

by any other supply-dealer using these same gauge-frames.

Well, after we began making these hives by the thousands, there began to be calls for a little variation, and I set to work trying to see if we could not accommodate the friends with their different tastes and notions, and still have the hive "Simplicity" enough so it would work interchangeably, as I have told you. The *body* of the hive is just about the same that it was when I first made it, with the exception of adding a permanent bottom-board. For obvious reasons, when this permanent bottom-board is added, it seems well to add, also, a portico, after the pattern of the well-known Langstroth hive, with its portico. To distinguish this permanent bottom-board hive from the regular Simplicity bodies, we call it the Portico hive, and the Portico hive is always used for the bottom story; in fact, it can not be used for an upper story, because you can not get the bottom off. Any Simplicity-hive body, however, will fit on top of it so as to make a two, three, or even four story hive. A good many of the friends who use the Simplicity hives prefer these portico bodies for the bottom story. Those who prefer a movable bottom, however, generally use a cover for a bottom-board, adding what we call an "alighting-board" to make it convenient for the bees and their owner. So you see we have only two kinds of bodies—a portico body with its permanent bottom, and the ordinary Simplicity body, without any bottom at all.

Now, those who first become acquainted with the Simplicity hive almost invariably object because we call a single body and a single cover a *hive*. They claim that a hive needs a bottom-board. But this complicates matters, as I will show you. Suppose a man purchases for his first hive a body and two covers; or, if you choose, suppose I should say that every hive should have two covers, that one might be used for a bottom. If the hive-maker has them put up in packages in this way, when you want a hive you would, of course, have one body and two covers. Pretty soon your swarm increases until it needs more room. Would it be convenient for you to buy another body and two covers to give the necessary room? By no means. All you want is another body to make your hive a two-story hive. Now, suppose the manufacturer sells one body and one cover. A swarm comes out, and you go to the shop and get a Simplicity hive, consisting of one body and one cover. Almost every dooryard affords a piece of board that will do temporarily for a bottom-board. When the swarm wants an upper story, you go to the shop and get another hive, consisting of *one body and one cover*. Now you are rigged complete with a two-story hive. Well, suppose the manufacturer makes a discount on a crate of ten hives bought all at once, what shall constitute this ten-er-ate? Why, I should say (and I have had long experience, mind you), a ten-er-ate should consist of ten bodies and ten covers; that is, they are ten one-story hives, or, if you choose to put it so, they are five two-story hives. When they are just two-story you have all the room you need.

If your colony gets strong enough so you use some of the hives three stories high, you have an extra bottom-board, or an extra cover, as you choose.

Now a word in regard to prices. I started out with the idea that the body and cover would cost about the same, and that good ones made of a fair quality of lumber should be afforded for about 25 cts. in the flat—perhaps a little less where a crate of ten is purchased at once, or may be a little more where a customer wants a little better quality of lumber used. I believe this has got to be a rule the world over, pretty much; that is, where *our* money is used—about 25 cts. for a cover, and about 25 cts. for a body; nailing and painting extra, according to circumstances. Nothing very complicated in the above, is there? Well, the complication comes in pretty soon. Lumber checks and splits and decays, especially if not kept well painted; and in the South the heat of the sun is a pretty severe ordeal for any sort of woodwork; therefore a tin roof becomes desirable; and one thing in favor of a tin roof is, that comparatively cheap lumber can be used if we have a tin cover; for boards that will work 16 or 17 inches wide, without knots or checks, cost a good deal of money. And not only can we use cheap lumber, but where we have a tin cover over the lumber, each board may be split in *two*, and be plenty strong enough, with its metal covering. I have tried many times, and have even sent to the tin-mines of England to get figures on sheets of tin, to see if I could not add a tin covering, and still stick to the old price. It can not be done, friends—not yet; but we have got so near it that, for just *six cents* extra, we can give you a tin covering that will last a lifetime, if you keep it painted. Now, most of you would jump at the conclusion, from what I have said above, that we can sell a sheet of tin that would cover a Simplicity hive, for six cents; but we can not do it. You will see *why*, from my remarks above. The tin *alone* is worth 9 cts., or a little less by the box. Another thing: While the tin cover is exactly what is wanted for a *cover*, it is not needed, nor, in fact, wanted, for the pieces you have for the bottom-board. It would be cold for the bees' feet, and might give them the "toothache" in frosty weather; so where we put up ten crates with tin for the covers, we can just as well omit the tin for those that are to be used for bottom-boards; but as we do not know how our friends who are to receive them may want to use them, we are obliged to make a separate table of prices for hives where covers are to be lined with tin.

Now, a good many want a cover that has capacity enough underneath to hold a case of sections; and by using half-inch lumber for it, and saving the expense of wide lumber (for a 1½-story cover is made of light narrow boards), we have succeeded in making such a cover at the same price as the ordinary Simplicity cover made of *No. 1 lumber*. But this cover will not do for bottom-boards either, so you see we have to have a separate table where this half-story cover is used. Now, then, the above seems to accommodate almost everybody, in the way of a

bee-hive. It includes two kinds of bodies—a permanent bottom-board body which we call a Portico hive on our list, and the ordinary Simplicity body. It also includes three kinds of covers—the Simplicity of wood, the Simplicity cover covered with metal, and the half-story cover. But all of these work together perfectly and indiscriminately. We can put any kind of a cover on any kind of a body, or any kind of an upper story on any kind of a lower story, and you can enlarge at pleasure by piling them up. But unless these things which I have mentioned are taken into consideration, a new hand is apt to get sadly puzzled over our tables in the price list. Those who have used Simplicity hives for years, have, I believe, made no mistakes in ordering hives.

ON THE HIVES CANADIANS USE.

WITH ALSO A KIND WORD SPRINKLED IN HERE AND THERE.

THE June number of GLEANINGS is at hand, and I read with much interest the genial letter of my old friend W. F. Clarke. His little remark in reference to my "experimenting with the Jones frame" calls for some explanation; and perhaps my experience may prove as profitable to others as that of others has frequently been to me. Far beyond all have I been benefited by a gentleman of Medina (A. I. Root), whom I engaged ten years ago to experiment for me in his own apiary, and report the results every month. He has never yet failed in doing so. He tried to convince me that the Langstroth frame was best for a northern climate, but has not yet done so, although his experiment last spring was certainly a successful one. He tried raising bees in hotbeds; that failed; just as he had me about convinced that manure and glass were going to do it, then the conservatory experiment also failed. Chaff hives of formidable dimensions next came to be the long-expected remedy for wintering and springing troubles; that, the winter of '80, '82, and '84 proved a snare. All these years I have been trying to profit by the line on which Mr. Root kept moving along, but seldom followed his lead, as I think such a man has a line which he alone can follow most successfully. This I think will explain why so many different sizes of frames are in use.

Several years ago, having a number of Jones hives in use I became satisfied that they were too deep for spring management, and the experimental stage is now so far past with me that I have 100 stocks in 9-frame hives, size of frame being 10x14, inside measure. I understand that Mr. Jones, who furnished my hives this spring, is now constructing a similar one, "reversible" in every point, which I have no doubt will be largely used as the coming hive. Is it not the case, that those who have lost most heavily during winters past have used the Langstroth frame? I refer more especially to open-air wintering, as I believe the L. frame and hive will winter bees in special repositories or cellars as well as any other hive used. But, how about springing? The essential points to me of successful wintering of from 50 to 150 stocks each winter, are plenty of good honey (not sugar, unless as a compulsory supplement), setting into a good warm cellar before severe frost sets in in the fall, 6-inch en-

trances open, sheet of factory only over the frames, perfect darkness, quietude, even temperature (about 44°). If these conditions are observed, I do not greatly care whether the cellar is damp or dry; they will "hibernate" very comfortably through all the changing seasons outside, quite as oblivious of passing time and winter's storms as those bats of the Mammoth Cave A. I. Root described to me the other evening.

Last, but not least, when you became a Christian (how well I remember when that number came) you undertook an experiment which has proved the greatest success of your life, and I trust for one you will still from time to time give to your great circle of readers a leaf from your life's chapter, as it goes on. How I wish our friend Mr. Jones, now that he has given us a *C. B. J.*, would "go and do likewise"! J. C. THOM.

Streetsville, Ont., Can., June 10, 1885.

Please accept my heartfelt thanks for your very kind words, friend T. May God help me to let my light shine in such a manner as will be most helpful to my fellow-men!—Speaking of the L. frame, I hardly believe you are correct, my friend, in saying that those who have lost most heavily have used the L. frame. The A. B. J. has given several tables in regard to losses, comparing the L. frames with other frames. If I am correct, it did not show any thing in favor of deeper frames.—I suppose your concluding sentence means that we should be glad to see Bro. Jones give us something in his paper, a little in the line of my moral talks; for I am happy to tell the friends who do not know it already, that D. A. Jones is not only a good sound man in every respect, but he is also a Christian, and a very prominent helper in the cause of Christianity and the upbuilding of churches and Sabbath-schools, and also in discouraging saloons, intemperance, and iniquity of every kind. I presume Bro. Jones will pardon me for telling this much of what I know.

FLORIDA.

ITS ADVANTAGES AND DISADVANTAGES FOR BEE-KEEPERS.

Concluded from last issue.

THE first questions one will naturally ask who desires to change his location are, What are the advantages and disadvantages of the proposed new location? I will try to answer these questions as well as I can, so far as Florida is concerned; but I shall try to be the most particular in telling the disadvantages, because the advantages have been told over and over again by writers from that State, who usually forget to tell the other side. Some, like Mr. Hart, tell both sides; but the majority see only one side.

First among its advantages is the unrivaled climate, probably the finest in the United States. Contrary to the usual rule in warm climates, winter is the dry season and summer the wet, the line between the wet and dry seasons being much more marked the further south in the State we go. This absence of much rain during the coolest part of the year, and its abundance during the warmest, is much pleasanter and more healthful than the reverse conditions would be. The absence of great

variations of temperature is also a very valuable feature of the climate, the extreme variation at New Smyrna being about 70°, from about 28° to 98° above zero, while at Cape Sable the variation is probably about 50° degrees only, from 45° to 95°. At my house here in Iowa, the extreme range is over 140°—that is, from 40° below zero to 103° above. Why the temperature should be higher in the northern part of Florida than in the southern, is a puzzle to many; but such is the fact, the extreme being sometimes 4 to 5° higher in the northern half of the State than on its southern coast. If climate only were considered, I should most decidedly prefer the most southerly location in the State that I could get. The great heat of the sun in Florida is always tempered by breezes from off the ocean or the gulf, and such sultry and oppressive days as we frequently experience in the North are unknown there.

Of course, the question of how to safely bring our pets through the winter possesses no interest whatever to a Florida bee-keeper, there being but very few days during the year but that they fly freely in the open air, and not an entire month but that they gather some natural stores.

The yield of honey that can be obtained in a good mangrove location is very large, that obtained by the bee-keepers of New Smyrna having averaged, for several seasons past, nearly 200 lbs. per colony per season. Mangrove is the most reliable and regular yielder of honey of any plant we know of, probably because of its roots always being within reach of salt water, and therefore not at all affected by drought. This is a positive and decided advantage.

I will now try to detail some of the disadvantages of living and keeping bees in Florida, and shall try to treat this part of the subject more thoroughly than any other, because it is less often written about.

The want of schools, churches, and good society is probably the most serious objection to the making of a permanent home in that State, and this is especially true with those seeking good locations for bee-keeping, as such locations are nearly all in the most unsettled parts of the State; and, what is worse, that part of the State which we suppose to be the best for bee-keeping purposes will be the last to be settled. The wilds of Florida are certainly poor places in which to raise families, at least so far as schools and the best aids to civilization are concerned.

Want of transportation is a very great obstacle; but this will, of course, be partly overcome in the future. At present the only way to reach most of the coast region is by means of small sail-boats capable of carrying a few thousand pounds at a time. Nearly all settlers on the coast who are able, own one of these boats, and they are almost the only "horses" the coast region possesses. On account of the high price of forage and grain, a much less number of horses is kept in the State than elsewhere; and whoever needs to hire team work done must expect to pay roundly for it.

Lack of mills, stores, etc., is quite troublesome. Nearly all the lumber in even as well settled a region as that around New Smyrna, has to be brought from Jacksonville by boat. Some sections of the State are well supplied with mills, but they are not frequent on the east coast yet. The Florida yellow pine makes excellent lumber for hives, and for that

reason only I think it would be best to obtain white pine from the North.

The prevalence of insects, such as fleas, mosquitoes, sand-flies, etc., is, without question, the great pest of Florida, and I have yet to see that part of the State that is free from them. A few simple precautions will usually keep fleas from troubling much. Mosquitoes are everywhere, but especially along the coast, it being a popular saying that mangrove-bushes breed them. The further south in the State one goes, the more plentiful are mosquitoes; and whoever finds a good bee location in Florida will be certain to find a first-class mosquito location also. They can be kept from troubling much in houses, by the use of screen doors and windows, and netting over the beds at night. I am told that they are excessively bad only a short time in summer, but one is never entirely free from them. Building one's house in an open, airy situation is quite a protection from them, as well as from sand-flies. These last are an unmitigated nuisance; but I think from what I could learn that they remain only a few weeks in the spring. Red-bugs and seed-ticks abound, but they troubled me very little indeed, although I was around in the pine woods and swamps while there, ten times as much as any resident needs to be. Scorpions are a needless terror to some people, their sting being but little if any worse than a bee-sting. Neither wife nor I was stung by one during our seven months' residence there, and no one fears them at all.

Insect enemies of bees are bad. Mosquito-hawks are very thick for a while in the spring, and it is yet a question as to how serious is the harm they do. A writer in one of the bee-journals lately stated that they were extremely destructive to young queens while out on their flight, sometimes destroying 80 per cent. The little experience I have had with young queens down there, leads me to believe that to be a decided overstatement, the large loss being from other and more controllable causes; but they probably do some mischief in that line.

Red ants would be a much worse pest if they were not so easily controlled. These ants work mostly at night; but after they once get commenced on a colony, they keep at it until the colony is used up, or until the bee-keeper heads them off. They have their nests in old stumps and logs, and when working on a colony they can easily be traced to their nest by the line of ants going to and from ants' nests, and all can then be effectually destroyed by fire. An energetic bee-keeper will in time destroy every ant within danger distance of his apiary. Both Mr. Olson and Mr. Hart, and, I think, Mr. Sheldon, told me that their losses had been insignificant from this source.

Bee-moths are, of course, much more plentiful in warm than in cold climates; but these have ceased to be bugbears to true bee-keepers.

The difficulty of obtaining reliable information about any special locality in Florida is quite an inconvenience. Nearly every resident there thinks his own locality is unquestionably the very best one in the State. This is quite a common state of affairs in all new sections; but I have never seen it any thing like as much so anywhere else as it is there. Ask a resident in almost any part of the State about the quality of land in his neighborhood, and he will tell you that "It is first class, good enough to raise splendid orange-groves without the aid of fertiliz-

ers at all;" but right over in the next county, south, the land is so poor it won't "sprout cow-peas," an expression equivalent to our Northern one of being too poor to raise white beans. Ask him if it is unhealthy, and he will answer that they "never have the chills," but right over in Sumter, or some other county, it is so "pesky sickly" that even the 'gators can't live there without getting the shakes. Ask about mosquitoes, and he will give a similar answer, all the time slapping with his hands, at some imaginary object, of course, between every other word. This trait, or, rather, habit, of overestimating one's own locality, and underestimating all others, is entirely too common to be comfortable; and all intending settlers should take the advice of some reliable friend there, or else wait until they know something about the country themselves before selecting their location. I know several persons who were turned away from the east coast by fabulous stories told them in Jacksonville about the mosquitoes and sand-flies of that region, but who are now satisfied they would have done much better than they have done, but for the influence of those stories.

The soil and climate of Florida are not adapted to the raising of the staple articles of food demanded by Northern appetites, such as dairy products, wheat, potatoes, etc., and these all have to be purchased from stores, of course not so cheaply as we get them north. All intending settlers want to take this into consideration when making their plans. Sweet potatoes, however, can be cheaply and abundantly raised almost anywhere in the State, as also many of our common garden vegetables. Fish are very abundant in nearly every section of the State, especially so near the coasts, and magnificent oysters are also found in many places along the coasts. The great abundance of fish is aptly illustrated by the reply of a native youngster: "Fish in summer and Yankees in winter," made to a tourist when asked what people in Florida found to live on.

I will now give some opinions or suggestions which may be of use to those going there intending to make a business of honey-raising.

Mangrove sustains an equal and I think a more important relation to bee-keeping in Florida than white clover does in our Northern sections; therefore only good mangrove locations must be sought after and relied on. I have already stated where such locations can probably be found; but others now in that State can probably give much additional information on that point.

Before going there, get all the information you can about the State at large. I think the most correct impressions I obtained were got from the writings of sportsmen, who have no interest in the State, except as a field for sporting and cruising. The best of these books I have seen are "Camping in Florida," by Charles Hallock, of the Forest and Stream Publishing Co., and a later work, "Camping and Cruising in Florida," by Dr. J. A. Henshall, of Cynthia, Ky. Quite a number of bee-keepers have written short articles from that State, some of them valuable, some worthless; but decidedly the most voluminous on bee-keeping subjects that we have has been furnished by Mr. Hart, of New Smyrna, who, in my opinion, is an uncommonly fair and candid writer. Persons settling in Florida must expect to have to rely mainly on their own judgment in selecting proper locations, etc., and

that State is like a new book on a new subject, and can not be learned in a brief period of time. If possible to do so, I would earnestly recommend all intending settlers to live for as many months as possible with families who are on their homesteads. More can be learned this way about the details of Florida life than by any other means I know of.

There has been so much romance thrown around Florida by writings and traditions, and various land agencies have sent out such magnificent descriptions of its climate and scenery, that nearly every one feels bitterly disappointed on entering the State. Its flat, sandy pine lands and swamps look dismally barren at first sight, and few indeed but feel very much disappointed during their first month's residence there. The unlovely and unwritten-about side of Florida first appears; the other and more pleasant part being appreciated only after getting acquainted. Unless this important fact is borne in mind by settlers, many will leave the State in disgust before they are capable of forming any correct judgment of what they do want. I remember now of meeting only one person while in the State who was satisfied during his first month there, and I do not now remember a single person who had resided there three or four years who had any desire to permanently remove north. This is an almost unheard-of state of things in any other new country. This looks as though Florida were like some people we know—not very impressive at first sight, but who stand acquaintance well—one of the highest compliments that can be paid any one.

Pioneering in any new country means a certain amount of hardship and privation. Florida pioneering is no exception to the general rule, and none but those whom nature or native resolution has fitted for such work should try.

The impression I have formed about California is, that whoever makes a business of bee-keeping there has to isolate himself among the mountains more or less, and contend with many difficulties and hardships. I judge that these difficulties, hardships, and the isolation, will be found no worse in the honey districts of Florida than they are there, while a good honey location in Florida has one very marked advantage over California—that of a much more even annual yield of honey. The mangrove has its roots in tide-water, and can not be affected by drought, and is certain to give a good paying crop of honey every season.

I hope to be able some time to investigate the resources of the southern coast of Florida; but friend Hart and others are likely to be able to do it before I shall be. Let us hope that some one will soon do it thoroughly.

All that we now know of the honey resources of that 300 miles of wild coast is, that the possibilities—yes, probabilities—of the future honey production of that region are as immense as our actual knowledge of their extent is at present infinitesimal.

O. O. POPPLETON.

Williamstown, Ia., Feb. 15, 1885.

I am sure, friend P., we are all very much obliged indeed for your very candid and faithful account of this attractive field for our industry. We are not all going to move to Florida, it is true; but I believe a great many of us have in mind some form of taking a trip down there—that is, if God prospers us; and we are therefore interested in knowing

all about Florida. There is one point, I believe, in your letter, not touched, of much interest to bee-men; that is, will the quality of the mangrove honey, or any other, compare with the California mountain sage? Some of the Florida honey is very fine, I admit; but to my mind there has nothing ever been furnished from any point on the face of the globe, of such exquisite flavor, color, and body, as the finest specimens of California mountain sage. May be people tire of it after a while, and I should like to know how the mangrove honey compares in this respect. Does it "stand acquaintance," as you aptly term it, say as well as our white-clover honey of the Northern States?

GERMAN CARP, AND THEIR HABITS.

HOW TO SEE THEM IN YOUR POND.

IT was the 13th day of June before I ever had a look at our German carp; and one reason was, that I did not know how to look for them. It is with carp as it is with finding queens, in looking for eggs in cells—yes, and in finding strawberries. A good many would go and look and say there was not any queen there, or there were no eggs nor brood. Your children, or perhaps your hired help, will say your strawberries are all picked. The man who owns a carp-pond will tell you he has looked and looked, and has never been able to catch a sight of one, and yet they are perhaps visible at every hour of the day. It is this same faculty of learning to see what there is to be seen in this beautiful world of ours, that we all want to cultivate.

Last Saturday evening I sat down by the pond after the labors of the day were over, and thought to myself that, with the numbers of fish there were in that body of water, I certainly ought to be able to see at least some indications of them. The setting sun was on the opposite side from me, and every ripple and tiny wave was most plainly perceptible. Pretty soon I began to notice peculiar eddies, almost like little whirlpools, and sometimes the water would seem to boil up in certain spots; and I noticed, too, around those spots that the weeds and water-plants were swayed in an eccentric sort of way. At first I supposed this swaying was simply caused by the breeze; but pretty soon it was evident that something was nosing around at the roots of the water-plants. Yes, it was the fish, and no mistake. The pond has always been muddy, so that we can not see much below the surface. Somebody said the carp make it muddy by rooting around in the bottom. Well, pretty soon one of these eddies appeared within a yard or two of the grassy bank where I sat. Then the grass began to be jostled about near my feet. Pretty soon something like the snout of a pig appeared just above the surface of the water, and then I saw it was the mouth of one of the large fish. He was nosing around, sucking in various substances, expelling such as did not seem to suit him. Well, when I began to understand what it was I was to look for, here and there I could see movements of the water,

indicating the presence of fishes all over the pond. Sometimes they would swing around so quickly as to make quite a loud "chug;" and once in a while a nose would come up clear out of the water, and their brilliant shining scales would glisten in the sun.

The next morning I provided myself with some crackers, to see if they would eat, and pretty soon I was abundantly satisfied. Of course, you have to keep still, if you want to see them behave themselves as if they were at home. If you do not, or if they catch a sight of you, they disappear in a second, sometimes with a tremendous swash of the water. I did not know whether I could keep Huber still enough to get a sight of them, but he took it all in an instant. "Oh! oh! oh! Hungry as little bears, aren't they, papa?" No wonder he thought they were "hungry as little bears," for I should think all the large ones in the pond were after the broken crackers I had flung upon the surface of the water; and such a nosing as they made, to gather up the fragments! The only way a fish has for telling whether a thing is good, is to swallow it part way; and if it does not suit him, he blows it out with a stream of water. On one occasion a black stick a couple of inches long came shooting right up in the middle of the pond. Afterward came the nose of one of those large carp. He shot it out as being unsavory, but immediately sucked in the crackers, with great satisfaction. No doubt we shall soon have them perfectly tame.

Now, there is one other thing I have discovered about our carp-pond, and I wish that Prof. Cook, or somebody else, would enlighten me if possible. Early in spring I saw great quantities of what I took to be frog's eggs—a disagreeable scum floating on the pond, full of little round balls about the size of shot. I remember of thinking I would skim them all off, so as to avoid raising such an army of frogs; but it was neglected, and by and by we had little polliwogs—millions of them. They came up in the shallow water, where we had provided a place for the carp to breed, and the little wigglers made a black fringe all around the edge of the pond. They just lay in heaps in shallow water. Well, some of them grew into large polliwogs, perhaps two inches long; but the most of them did not get larger than a common cricket, some not larger than house-flies, before they turned into veritable hopping toads, and they covered the bank so they resembled a swarm of bees—little black toads the size of crickets, or smaller; and when I came down among them, instead of plunging back into the water they climbed over the bank of the pond and hopped off into the woods. Now, then, do tadpoles (we call them polliwogs) undergo transformation at all ages and sizes? There can not be as many different varieties as there are sizes, because they lose their tails and put on legs at every possible size from that of a house-fly up to two inches in length. Some of them seemed to turn into frogs, and some into toads, or tree-toads, any way; and the whole lot came from one batch of eggs, evidently. I had rather hoped the carp would turn in and gobble them up, so as to rid my

pond of their presence; but the carp seemed to very much prefer rooting around among the weeds and rubbish in the bottom and along the edges of the pond, not troubling themselves about any thing in the shape of animal life. Our carp seem to be vegetarians. No wonder they grow enormously during a single season. If you should see them around with their great mouths, taking in all sorts of trash, every or any day, the wonder would be if they did *not* grow.

A BUNDLE OF QUERIES FROM ONE OF OUR A B C SCHOLARS.

ARE QUEENS OFTEN SUPERSEDED BECAUSE THEIR WINGS ARE CLIPPED?

I AM very much pleased with Mrs. Culp's plan of managing an apiary. If we farmers can practice the same successfully, we can keep a few colonies without being compelled to stay within hailing distance of the house all through swarming time; but with me it has not proved successful with the Italians. Of course, I am only a beginner, and may have made a great many serious mistakes; for instance, last season I had one colony that would persist in building queen-cells; and when I put the sections on I could not examine them until I took them off in the fall, so I forgot all about queen-cells until one warm day in February, when the bees carried out the old queen and two young ones; then I looked, and found three empty cells and a young queen that proved to be unfertilized. I should like to know if bees often supersede their queen because her wing is clipped. Also, when there are two queens in one hive, does the younger generally kill the older, or the reverse? Why does Mr. Doolittle say, "Remove all the drone-comb from the hive, except an inch or so"? Why leave that inch? and why does he charge twice as much for a tested queen two years old as one only one year old? I thought queens lived only about three years.

What do you mean by the German, or brown bee? Are they the common black bee?

Is alsike clover a biennial or perennial? and does it propagate by runners, like the white, or from seed only? It is a new thing with us, the first being sown this spring.

Is alfalfa a good honey-plant? It does well here, but there is none within range of our bees.

Brock, Neb., June 8, 1885.

J. S. JOHNSTON.

We have sometimes thought that the bees objected to a clipped queen; and as a good many people have their own notions in regard to the matter, we have discontinued clipping queens.—My experience has been, that when there are two queens in a hive, mother and daughter, there is no killing at all. The old queen lives at home peaceably until she dies and is carried out.—Why leave a little drone-comb in the hive? Friend J., Mr. Doolittle recommends a little drone-comb, to satisfy the bees. If you cut it all out entirely, they will tear down worker-combs and work them over into drone.—Mr. Doolittle charges as he does for those two-year-old queens, because they have been tested for queen-rearing; and when you have one, you can go right to work and start a hundred queens if you wish, being pretty

sure that they will all be nice ones. It is a good deal of labor testing a queen for queen-rearing, and they ought to bring a good price, even if they are old.—The terms German bees, brown bees, black bees, and common bees, all mean one and the same thing. If we could agree on some one term it would be an excellent idea, but I do not know whether the friends would all agree as to what our native bees should be called.—I suppose alsike clover would be called a perennial; and although it may come up again for several seasons, it usually runs out mostly in three or four years.—Alfalfa is said to yield considerable honey in many localities in California. The bees seldom if ever work on it here.

CLIPPING QUEENS' WINGS.

SHALL WE HAVE THEM CLIPPED OR NOT CLIPPED?

IF I mistake not, I have seen somewhere in GLEANINGS, within a year, that friend Root did not clip the wings of his queens, and believed the practice to be a bad one. As far as friend Root is concerned, together with the way he runs his apiary, for the sole purpose of selling queens, and bees by the pound, perhaps such advice is all well enough; but when it comes to the majority of apiarists, especially those working for comb honey, where more or less natural swarming is sure to be done, I can not help but think the advice is not sound. Why I speak of the clipping of queens' wings at this time is that, had I not kept the wings of my queens clipped, I should have lost a valuable queen and colony of bees last Sabbath.

A few days ago I looked over all my strongest colonies of bees to see if any needed feeding, as we always have a honey-dearth here after the fruit-bloom is over and before white clover opens. In thus going over the yard I failed to find any preparations being made for swarming. It often happens that a colony which is well supplied with stores will prepare for and swarm during this honey-dearth, and for this reason I carefully examined all such, so that I might know if any watch of the apiary for swarms would be needed. As I found no signs of swarming, no watch was kept. Imagine my surprise, but two days later, just after we returned from church, to hear Mrs. D. call out, "The bees are swarming!"

Upon going to the apiary I found the bees rushing out of my best colony by the thousand. The queen was soon found, and placed in a wire-cloth cage, which was hung on the small twig of an apple-tree which the bees were beginning to cluster upon. I now went to the shop and got six frames of comb to put in a hive which stood in the apiary, and prepared the same for the reception of the swarm, when I went to the house for a moment while the bees were finishing clustering. As soon as I thought they were sufficiently clustered I started to hive them; but before I got where they were I saw that they were just commencing to uncluster, preparatory to leaving. I hurried to them; but before I had gone two rods they were on the wing, and in a moment more were taking a "bee-line" across the fields for the woods, at a rate which defied the ordinary speed of most people who run. After being gone for some time they found they had left the queen behind, when presently they came stringing

back, and began clustering on the same twig about the queen; and after clustering the second time, they were hived. Now, had not this queen been clipped I should certainly have lost a queen valued at \$10.00, and a good swarm of bees, which, if the season proves good, will produce me \$5.00 to \$10.00 worth of section honey. Supposing she had not been clipped, and they had come out an hour or more earlier (it was two o'clock when they swarmed), as swarms as a rule usually do, I should probably have concluded that the queen had been superseded when next I examined them, and been none the wiser regarding the swarm, unless I had inspected the colony before they had filled up with young bees. If they had come out a few hours earlier, as the queen was clipped she without doubt would have returned to the hive when the bees came back, and swarmed the next time when I was at home.

A good many seem to think it is troublesome to hive swarms where the queen is clipped; but with me I can do it full more easily than I can when the queen goes with the swarm. But, suppose it were, as some think, could I not well afford to be at considerable trouble for the \$15.00 or \$20.00 I have saved in this case?

The complete control you have of an apiary where all the queens have clipped wings, gives a man a certain confidence which is worth far more to me than all the trouble which might occur to a novice would amount to. Another thing: Should the bees sometimes bother by mixing up or entering wrong hives, etc., there is always a comforting thought about it, which is, the bees are always in the apiary, where they will be bringing in the honey just as well as if they were exactly where you at first desired. With Prof. Cook, Dr. C. C. Miller, and others, I advise all working for comb honey to clip the queens' wings. 16—G. M. DOOLITTLE, 80—40.

Borodino, O. N. Y.

No doubt if I were raising comb honey, friend D. I would have my queens clipped; but I believe there are quite a number of comb-honey raisers who decide they do not want any more clipped queens. The objections are, first, that a good many facts seem to indicate that bees sometimes displace a queen after a wing has been clipped, or at least attempt to displace her. I am inclined to think this is a mistake; but as a good many seem to have got the notion into their heads, we have been obliged to stop clipping ours, when sending them out for sale. Quite a number of our customers have declared that they will not have a clipped queen at any price. Second, if I am not mistaken a queen is often lost where she is clipped, where she would not have been lost if she had had the use of her wings. Suppose the swarm had come out while you were at church, are you sure a clipped queen would have got back into the hive? or what does happen usually when a swarm comes out with a clipped queen, when no one is around? I have several times followed them quite a piece across the apiary where they had hopped along. I found them by the few bees that were buzzing along the track they had taken; but I have reason to think that a good many were lost in that way when they were never found. You may say that we had better lose the queen only, than to lose the queen, bees, and

all; and I do not know of any way of managing bees without a liability of such losses, unless somebody is on hand to look after swarms as they issue. Our perforated zinc and drone-traps ought to fix the business; but somehow we do not get many definite reports as to how these fixtures do work. How is it, friends? Shall we clip our queens where we are working for oomb honey, or shall we let them go unclipped? We should like to hear from a good many in regard to this matter.

A LETTER FROM ONE OF THE RECLAIMED.

YES, MY FRIENDS, AND FROM ONE WHO HAS BEEN RECLAIMED BY THE GRACE OF GOD.

FRIEND AMOS:—After using and abusing tobacco for forty years or more, I have quit. I use it in no form whatever. I quit the habit at once, which threw me into a high fever. My pulse was 120 per minute, and I was so roasted with this fever, and at times had such an all-gone, idiotic feeling, that I took to it again. In a few hours the fever was gone, and I felt right in *body*, but not in mind, for I was *whipped*. In a few months I reinforced and made another "bulge" on old *flesh* and *Satan*, but I was not successful; that tormenting fever rose again; my pulse beat 115 per minute, and again I poured nicotine on the troubled waters, and there was a calm. My friends told me I was too old to quit, and that I was foolish for punishing myself in this way; that I could *not* quit. I told them I had better die trying than to continue to live in sin, feeling as I did that the use of that poisonous, stimulating drug was a barrier that prevented the full flow of the love of our heavenly Father into my poor thirsty soul. After being defeated in this way, and having to surrender unconditionally, I concluded to dig a trench around the city, lay siege, and starve my enemy into submission, concluding that, as my system by degrees accommodated itself to the use of tobacco, in a like manner it could be trained to the disuse of it. So I made or commenced the third attack on *flesh* and *Satan* by using none before breakfast; but, oh what a fuss, dust, and outcry was raised over this innovation on the habit of forty years' standing, by the old totally depraved humanity and *Satan*! But the Lord helped, and continued to encamp on the battle-field, and this victory was followed up by using less and still less every day. As Mr. Bunyan says, I put a guard at mouth-gate and feel-gate, and then reinforced every morning by asking God to help me to quit, if it was his will I should quit, and in this way I tapered off until I used none at all.

Everybody engaged in this fight should be very watchful, or the "tapered" end will be the larger. By the help of God I am now a free man; and as the odor of pipe and tobacco is not pleasant, I suppose my appetite, taste, feeling, etc., are getting back into the natural channel again, and I have the use of my mind and body both, better now than when I used that stimulating, sickening, poisonous, narcotic, filthy drug—no, no; not filthy *drug*, but filthy *habit*, and my appetite is not ravenous and changeable as it was, and sleep comes when I call for it.

But the trophy of great value that I brought off from this battle-field is a calm, serene, sweet frame of mind that I never felt before, and I have a near-

er approach to my heavenly Father, and I am now nestling in his love. For many years back, my conscience has been ill at ease with regard to the use of this so-called "creature comfort." The following reflections gave me smarting, biting convictions:

"Will you not thank God for that quid of tobacco?"

"No."

"Why?"

"Because it is a deadly poison, containing no nourishment; it injures the digestion and nerves, and hurts my eyes, so I can not thank him for it and be honest and sincere."

Red-hot wires were then drawn across my conscience in this shape:

"If you can not thank God for the weed to use as a diet, quit it; for you are commanded to use nothing but what you can use in the name of the Lord Jesus; and, again, in every thing give thanks; and, furthermore, by your own confession you are guilty, or will be guilty of self-murder, being broiled and scalded in this way."

I squirmed and fought and ran and fell; but God helped me up on my feet again, and, "by grace I am what I am," a free man. The storm is behind me, and I am camping on the battle-field, awaiting orders from the Captain of my salvation to go and report at headquarters, and receive my promised inheritance.

And now in conclusion, let me tell you that I do not write this to you in order to get a smoker; no, no. I am using the one that I bought of you. When I received it, one screw was loose. I tightened it, but it came loose again, and was lost; but the smoker is doing good work, though it is traveling on three legs. I have written the foregoing, hoping that you will dress it over so it will be fit to be seen, because I have neither brains nor education; but if all or any part of it will help one man or woman to become free, who is now a slave, I shall be well paid.

J. M. STEEDMAN.

Quitman, Texas, May 3, 1885.

Friend S., I thank you for your little story, as it teaches me a lesson. Some of the friends here in the establishment insisted that they could break off better to take it a little bit gradually, than to cut loose all of a sudden. I objected to this way of doing, and I do yet. It seems to me dangerous to dally with sin; and yet the fact that you conquered in that way makes me feel that I ought to be careful about dictating a course for others. God saves, and he seems to have peculiar methods of saving different individuals. But he *does* save; and may all honor and glory and praise be to his holy name!

FUNGUS SPORES FOR BEE-BREAD.

A NEW KIND OF POLLEN.

YOU know, Mr. Editor, that what is one person's meat is another person's poison. That is literally proved in a case reported to me by one of our graduates, O. L. Hershiser, of Water Valley, N. Y. He sends me a twig of wild blackberry, which is badly attacked by the blackberry or raspberry fungus. The leaves are thickly coated with this yellow fungoid growth, which I believe, according to our best fungologists, is a very hurtful enemy to the plants. Mr. Hershiser states that the bees are thronging these plants where

"they gather this fungus with great apparent greed." Mr. H. asks if there is any danger from its becoming a substitute for pollen. I answer him, that I should have no fears. When Dr. Beal and I have been examining the ingesta of bees we have more than once noticed spore-like bodies in the intestines of the bees. Here we have positive proof that bees come by such spores legitimately. Bees appreciate a good thing when they see it, and care little where they get their albuminous food, whether from the anthers of flowers, the spore-cases of fungi, or the meal-bag. Every good wholesome albuminoid is appropriated with equal eagerness, if in a dust-like form suitable for transportation, according to the rules and requirements of bee-commerce. We see, then, that the old maxim is sustained; for this fungus, while it drinks up the life of the plants, yields up life-giving food to the bees. Bee-bread—plant-poison.

Prof. L. H. Bailey informs me that the scientific name of the orange-rust of the blackberry and raspberry is *Croema luminatum*. A. J. COOK.

Agricultural College, Mich., June, 1885.

This matter has been mentioned before, friend C., if I am not mistaken, in some of our bee-journals. The bees store the substance just as they do pollen, and it increases brood-rearing enormously. I never heard of its doing any hurt in the bee-hives, for the bees understand their business of preserving food a little better, if any thing, than the managers of refrigerator cars, and other like institutions. Some years ago I mentioned bees making some use of a quantity of mites that they found on the shelves of a cheese-factory. Under the microscope the dust was a mass of wriggling insects; but the bees packed them on their legs, and carried them home all the same.

FALSE STATEMENTS IN REGARD TO THE HONEY BUSINESS OF OUR COUNTRY.

As a protection to our bee-keeping population, we propose in this department to publish the names of newspapers that persist in publishing false statements in regard to the purity of honey which we as bee-keepers put on the market. When any paper will correct the matter publicly, with suitable apology, the name will be dropped. A copy of this article will be mailed to the editor of any paper giving place to such statements, with a written protest, before the name of the paper is given. After the lapse of a suitable time, if the matter is not corrected we will keep a standing notice, to warn the people at large that said paper does not scruple to give publicity to this class of falsehoods.

MORE ABOUT THE SOUR APPLE-PARINGS.

HERE is an article clipped from our county paper. I don't put any confidence in it, but it hurts our business to have the honey-consumers think they are buying glucose or some other poor stuff. I wrote the editor a line on it. What do you think of it?

A. W. LINDSEY.

West Brooklyn, Pa., June 8, 1885.

SECRETS OF THE TRADE.

Well may it be said, that as we live we learn. The discussion of the canned-goods subject has brought out some curious secrets of the trade. For example, it is learned that the "canners" sell the cores and parings of apples to the makers of so-called jellies, who, by the aid of different essences, turn out substances which are beautifully labeled as popular gelatinous products. When the parings, etc., become too decomposed to be used for jellies, they are sold to the manufacturers of "strained honey"; and it is asserted that none of the stuff so designated found in the market contains any honey whatever.

We never know what blessings are in store for us, and doubtless before long we will hear more of the benefits to be derived from cheap food.

That is the talk, friend L. Just send along all such notices. But, please give the name of your county paper; also please show the editor the article on page 410, in last month's issue, and ask him if he won't be so good, as to correct the tendency of his little item, headed "Secrets of the Trade." His comments seem to be in a sort of a strain of pleasantry, as if he had no faith in such stories; but after all, such items are harmful, and in all probability he does not want to harm anybody, even by implication.

Please find part of newspaper on adulteration of honey, as you request in GLEANINGS.

Harpersville, N. Y.

GEORGE RICHARDS.

ADULTERATION OF FOOD; THE EXTENT TO WHICH IT IS PRACTICED BROUGHT TO THE GOVERNOR'S ATTENTION.

Albany correspondent N. Y. Tribune.

"I have been astonished lately at the extent of the adulteration of food," said Governor Hill, glancing over the canned-goods bill a few days ago. "It would seem," he continued, "that every thing we eat is adulterated. In hearing testimony about this canned-goods bill, for instance, all kinds of imposture and deceit of customers were brought to my attention. This adulteration of groceries is becoming a national evil; one that we shall have to adopt severe measures to check. France is an elysium for those who desire to buy pure articles when they go to the grocery. The French government have taken extraordinary steps to protect the people—steps that perhaps could not be taken in this country, but the object has been accomplished. When you buy pepper in France, you know you are getting pepper, and not some weak adulteration of it; and so it is with all other articles.

"One of the measures of the French government to check adulteration which have proved successful, is a law which compels every grocer, when convicted of the crime, to place a large placard in his store-window, and keep it there for a year, with the words inscribed upon it, 'Convicted of adulteration.' Some curious facts were revealed by the packers of canned goods in private conversation. 'You would not think the parings and cores of apples of any use, would you?' said one of the packers to a friend.

"He then continued: 'Well, a fruit-packing establishment makes use of every thing; like the pork-packing factories, which save every thing except the pig's grunt. When we are packing and drying apples we have tons and tons of parings and cores. These we sell to the makers of jelly. All kinds of jellies are made of the material. You can not buy real currant jelly in the groceries. Every bit of it is apple, with some essence in it. But that is not the sole use of apple-parings. Occasionally we keep them so long that they can not be converted into jelly. Then we sell them to the makers of strained honey. All the strained honey that you see in the market is made of it—there isn't a bit of honey about it.'—Democratic Leader, Binghamton, N. Y.

Thank you, friend R. There is one good thing in the clipping you send us, and that is, about making grocers keep a placard in their windows. In our country, the grocer might as well put up his shutters and stop business as to do that. Following out the same thought, why would it not be an excellent idea to compel newspapers to keep a placard in large type, in a prominent place in their columns? Suppose we have a placard reading something like this:

"CONVICTED OF PUBLISHING SLANDEROUS STATEMENTS."

The above communication, some way or other, seems to mix up the Governor's name with this sour-apple-skin fraud. Now, Mr.

Democratic Leader, we call upon you to correct the impression you have publicly given, that all the strained honey seen in the market is made of sour apple-cores and parings. Come to think about it, it was only a year ago that these same papers informed us that all the jelly used in the United States was made entirely of old boots and shoes. What jelly will be made of in 1886 remains to be seen.

BEEES BY THE POUND.

BY request of friend W. Z. Hutchinson we copy the following from the *Country Gentleman* of June 11, 1885:

Eds. Country Gentleman—You will, perhaps, remember that the writer mentioned, in a recent article, that those who had lost their bees might find it advisable to buy bees by the pound. He followed the advice that he gave others, and has lately received from Tennessee thirty-two packages, each containing a queen and nearly three pounds of bees. It may be of interest to bee-keepers to know in what way they were put up for shipment, and how they were treated on arrival.

The shipping cages, or boxes, were 7½ inches deep, 11 inches wide, and 15½ inches long. The sides were of half-inch lumber, and the ends of stuff not more than three-sixteenths of an inch in thickness. Quite a point is made of making the cages as light as possible, in order to save express charges. The tops and bottoms of the cages are of wire cloth. The food for the bees to eat while on their journey is prepared by mixing powdered sugar with honey to the consistency of a stiff dough. At one end of each cage, upon the inside, is a slanting shelf, or rather trough, formed by placing the lower edge of a thin piece of board, 3 inches wide and as long as inside width of the cage, against the end-board of the cage. This piece of board projects inwardly and upwardly, from the end of the cage, forming an angle of 45°, it being held in place by cleats nailed to the sides of the cage, the ends of the board resting upon the cleats. It is in the trough formed by this board and the end of the cage that the food is placed. When every thing is in readiness, the cage is, of course, weighed, and then bees shaken from the combs into it, until it contains the requisite amount. In order to be certain that the queen is in the cage, it might be well to cage her until the bees are all in, then put her in with them and close up the cage at once. When the cages are all filled with bees, two of the cages are placed side by side, and strips of thin board tacked across their ends, thus fastening them together and virtually making one package of two cages. Neither does the matter stop here, for one of these double cages is placed four inches above another double cage, and the two fastened together by upright pieces of lath nailed on at the corners and sides. The lower ends of the lath project four inches below the lower double cage, thus forming legs to support the cages and keep them off the floor. Fastened to the upright center side-pieces of lath, was a light rope that passed over the top of the cages, thus forming a handle to lift and carry them by. Upon the top of each "nest" of cages was the consignee's name and address, a business card stating where they were from, and a placard which read as follows: "Living bees; keep this side up. Please handle with care, and keep out of the sun. Please sprinkle with a little water daily, at noon." The bees were three days in transit, and arrived in the best possible condition; in no cage were there more than 50 dead bees, and in some of them the bees had built comb, liquefied some of their food and stored it in the comb; and in two instances, the queen had laid in the comb!

It was evening when the bees arrived, and they were sprinkled with water, and left undisturbed until morning, when each swarm was found quietly clustered in the top of its cage. The cages were so carefully separated that the clusters of bees remained unbroken. A hive for each cage of bees had been previously prepared by filling it with clean, dry combs; each outside comb, however, contained a little honey. The wire cloth was carefully

removed from the bottom of a cage, the cover removed from a hive, and the cage set down upon the frames. The cage did not of course cover the entire top of the hive, and little pieces of boards and strips of cloth were laid around the cage until the top of the hive was covered. If any little cracks or holes were left, they were stopped with damp earth. The object of all these precautions in completely covering the top of the hive was, that the bees might be compelled to pass down through the hive and take their first flight from its entrance, for the reason that, after its first flight in a new locality, a bee will return to the exact spot from whence it flew; if it flew from the top of the hive, it will insist upon going in at the top, and if it can not get in at the top, it is some little time before it finds and uses the lower entrance. When every thing was in readiness, the hand was brought down with a "spat" upon the wire-cloth covering of the cage, which dislodged the bees and sent them down upon the combs. A cover was then laid over the top of the cage, that the bees might see no light except at the entrance of the hive. They flew from the entrance right merrily. In some instances a comb of brood was placed in the center of the hive before putting the bees in; and when it is possible to do so, this plan is advisable; in fact, if there were strong colonies in the apiary that could spare the brood, it would be well to give three pounds of bees as many as four combs of brood, as the bees can easily care for it. The express charges were \$14.

W. Z. HUTCHINSON.

It seems from the above that the cages used for these 3 lbs. of bees were nearly as large as the one-story hive. It has been our custom, when so many as 3 lbs. were wanted with a single queen, to put them into a Simplicity hive, with a couple of combs (wired, of course), containing the stores for their use in transit. Of course, a cage made expressly would be lighter; but when the purchaser gets it, it is of no value to him.

THE SOLAR WAX-EXTRACTOR, AGAIN.

FRIEND COON TELLS US HOW TO USE IT.

I SEE by what you say about the sun extractor that it don't seem to be a success out there, on account of the sun not being hot enough. Well, the way I make them I can melt out wax or honey, candied in the comb, with the thermometer anywhere above 60, and strain the honey and wax all at the same time. I make a box 4 or 5 feet long by 10 inches wide on the bottom, and 20 wide on top; then for the top part I make a frame the same size as top of box, 3 or 4 inches deep, with saw-cuts run on the inside ½ or ¾ of an inch apart, 3 of them, so that I can use 1, 2, or 3 thicknesses of glass, according to the heat of the sun, by sliding glass 12x20 into the saw-cuts. The box is lined with tin, then part way between the glass and the bottom I place a frame with wire cloth; on top of that I put strainer cloth; on that my comb-scrapers of honey, candied honey in the comb, or any comb honey not salable in the comb, and get pure clean honey below, and the clean wax on top of the honey, and have a faucet in the bottom to draw off the honey. I think a machine of that kind will work well anywhere east, or wherever the sun shines at all in the summer, and it saves lots of work; for all you have to do when you have any waste honey or comb is to put it in under the glass. All is tight, and you can draw off your honey whenever you have a mind to. Mine will hold about 200 lbs. of honey before I have to draw it off.

LeMoore, Cal., June 6, 1885.

O. E. COON.

HEADS OF GRAIN FROM DIFFERENT FIELDS.

WHAT TO DO WITH THE COVER OF A HIVE WHILE THE HIVE IS OPEN.

IN GLEANINGS for April 1, page 233, I find an article from Dr. C. C. Miller, on the trouble of removing heavy covers, when feeding; so I will tell you how I do it. My covers are made of $\frac{3}{4}$ stuff, 8 inches deep; the top is of one piece. They rest on a ledge $1\frac{1}{4}$ wide, $\frac{1}{2}$ inch from the top of the hive. Put a small nail or screw near the middle of the lower edge of the cap, and another below it in the ledge. Attach a twine to each nail, just long enough to hold the cover in place when it is raised, like an open trunk, and the work is done. If your ledge is not wide enough for the top to rest on, a couple of nails will answer. Now with the coffee-boiler of feed in one hand, raise the cover with the other, put in the feed, and close it, and the work is done without lifting the cap off. No covers to blow off; no hinges nor hooks, no springs nor clamps, but two small nails and two feet of twine, which can be attached to the screw-head by a little loop, so it can be easily taken off.

J. L. WOLCOTT.

Bloomington, Ill., April 23, 1885.

In the above arrangement the string is made of such a length as to permit the cover to tip over back, just far enough to stand safely, or, as our friend says, like the lid of a trunk. One objection I should have to it is, that the string would be right in the way for manipulations of many kinds. A string at each end of the cover, exactly as covers to trunks are fixed, would obviate this, but it would be more complicated. For many years, hive-covers have been made so as to open in this way, or similar ways. When we first made the Simplicity hives, the covers were hinged on. As it afterward became evident that many times the covers were an inconvenience when thus hinged, we made a hinge so they would slip off. Then it became necessary to have the attachment so made that any cover could be quickly attached to any hive. But this was found to be a matter so difficult to manage that hinges were abandoned entirely. Where a stake is put on the south side of a hive on which to train a grapevine, the cover may be tilted back against this stake, and I like this plan better than strings. Some apiarists while examining a hive use the cover for a seat, standing it on end. Others lean the cover against the hive. I believe that, as a rule, though, most of our friends find any sort of a string or wire or similar attachment rather a hindrance than an aid.

INVESTING \$200 IN A CARP-POND, ETC.

I have just received GLEANINGS for this date; and if I were in a joking mood, I should feel like joking you concerning your carp items. Right here I wish to thank you for the explanation concerning the annoying delay. What I would joke you about are the strange sentiments expressed in the reply to Mr. Best, though I think you intended to have the same apply to his particular case. Of course, there could be no need of his spending \$200 on a carp-pond 70 feet square, probably not $\frac{1}{4}$ of that sum. You make a very wild remark, however,

when you say you would not advise "anybody" to make a pond, etc. Again, you speak of receiving a specimen of *German* carp. The A B C will inform your readers that the only *German* carp in this country are the very few in the Government ponds at Washington. Your carp are no more *German* than I am a Frenchman, simply because I have traced my lineage to France. You make a grave mistake by feeding your carp, if you have a supply of water-plants in your pond.

MILTON P. PIERCE.

Philadelphia, Pa., June 1, 1885.

Friend P., what I meant by not advising anybody to make a carp-pond just now, with the idea of making money by it, was, that I hated to see young friends just starting in life, perhaps in cramped circumstances, going into these new industries with the idea of getting their money back in a short space of time. Of course, where carp is sold to stock other ponds, a very profitable business may be done; but what I had in view was the idea of putting carp on our markets for food. I would not advise anybody to go into it unless the party had money to spare so that he would be well able to stand a failure, and I would say the same in regard to many other industries—even bee culture. If your means are limited, do not invest very heavily to start with.—In regard to the carp we have, they call them *German* carp at the State hatchery, and I think they are real pretty, no matter what you call them.

CANDIED HONEY IN THE COMBS.

A neighbor of mine lost 43 out of 45 stocks of bees in American hives. There is 500 or 600 lbs. of honey, I judge, in the frames. He has the hives cleaned out, all dead bees brushed away, and empty combs cut away. I think the honey will not taste of any thing confined in the hives. I examined some to-day, and found some combs with the honey *candied*, especially those a little aged. Now he wants me to extract or get the honey out in salable shape, offering me one-half the honey for my trouble. I simply want to know my best plan to accomplish it and get it in marketable shape. Can the thick and candied honey be thinned to extract?

Nevada, Ohio, June 11, 1885.

WM. M. YOUNG.

It is a pretty hard matter to get candied honey out of combs. If it is not warm enough so the extractor will throw it out during some of our hottest summer days, I do not know how you can arrange it. If it was in your sized frames, I recommend it to rear brood. I am afraid the honey will not have a very good flavor any way you can manage it. See next page.

CALIFORNIA AT THE PRESENT DATE.

The meeting of the Central California Bee-Keepers' association came off in due course at Hanford, as advertised in GLEANINGS; but the beesmen all had long faces till after dinner, when they looked better. Bees are in a state of semi-starvation, getting barely enough to live on—the first time such a state of affairs has been known here. The reason is, no flowers. The grasshoppers are taking all the alfalfa bloom before it comes out; and our only chance for natural supplies for next winter seems to be what may come after the hoppers have died. There is good hope yet. My bees have gone from

42 to 50, but some of the new swarms have required a little help.

Mr. Wheeler showed his section-closing machine, which can easily be made to fit any section. It seemed to work very well, closing the section with one lever and throwing it out with another; simple and effectual.

Mr. Decker brought to the notice of the meeting a disease among his banded bees, not affecting the blacks. They become black and shiny, like old robbers, and the strong bees having nothing else to do seem to be wholly occupied in dragging out and finishing the sick ones. None of our bee-men can tell what it is. Can you enlighten us on the subject? [See A B C book, "Diseases of Bees."—ED.]

I notice that on pages 392 and 393 of last GLEANINGS Mr. J. P. Israel thinks he has the largest yield on record for his bees. If he refer to GLEANINGS for Nov. 15, 1883, page 712, he will find my report of 777½ lbs. per stand, spring count, and no account made of at least 50 lbs. to each hive in lower box, which I never interfered with; that over 20 hives to which the four had increased, I sold 2 and had 18 for 1884, which increased to 42, and gave only 3600 lbs., which I did not think worth reporting, so perhaps my bees are ahead of his for the blue ribbon he speaks of. GEORGE HOBLER.

Hanford, Cal., June 9, 1885.

GETTING POOR CANDIED HONEY OUT OF OLD COMBS.

Bees are doing finely; have commenced on alsike and white clover, and honey is coming in fast. My hives are all full of bees again, and I am selling queens and nuclei. All the black bees are gone—none but pure bees for miles around. Those wishing to get poor honey out from the combs can do so by uncapping and soaking the combs in water twenty-four hours, and then throw out with extractor. Mine will not come out without the soaking.

M. H. HUNT.

Bell Branch, Mich., June 15, 1885.

Friend Hunt, we are glad to know that your hives are filled up again, and that the bees are once more booming. Thank you for your suggestion in regard to getting out candied honey. I thought I was up to almost all such "tricks of the trade," but I must confess you were ahead of me there.

EXTRACTING DOES IT INJURE THE EGGS?

Last week I did my first extracting, something never seen before in this section. In two hives I found some frames in the upper tier that had about two-thirds of the cells with eggs in them. I extracted the honey from those frames, and replaced them in the hives, intending in a few days to use them for the brood-frames in dividing a very strong colony that showed indications of swarming. Imagine my surprise this morning, on examination to find that the bees are again filling the upper third of the cells, while the lower two-thirds still contain those same eggs, *unhatched* that they did six days ago; and there is no indication that they are going to store honey in those cells that contain the eggs. Those frames were out of their hive about thirty minutes. Do you think that keeping them out that long was the cause of their not hatching? Or is it possible that they may have become chilled some cool night, by the bees all leaving the upper story and clustering in the brood-nest? I find nothing of the kind mentioned in my A B C. Will not the bees

appropriate those cells containing the *dead* eggs this season at all? One thing more: In every one of the frames from which I extracted the honey, there was a single row of cells near one end, extending from top to bottom, out of which the honey would not come. It did look strange to see this single row of cells appear in every frame, while every other cell in the frame would be empty. It is something that I could not account for, any more than the dormant eggs already mentioned.

I want to ask you if cockroaches are an enemy to bees. I scarcely ever lift the cover off from a hive but that I see three or four of them hustling around on the enamel sheet, sometimes dropping down among the bees, without, however, causing any perceptible disturbance. L. HALL.

Sparta, Miss., May 26, 1885.

Friend H., I do not think the extracting had any thing to do with the eggs mentioned. Keeping eggs out of a hive half a day will not injure them at all, unless the weather is quite cool—much cooler than it probably was when you did the extracting.—The row of cells you speak of, from which the honey would not come, I presume came opposite one of the tin bars on the extractor-frame.—We do not have any cockroaches here, but they have been several times mentioned. If I am correct, they do no particular harm.

BEES THAT WORK ON RED CLOVER, AND BEES THAT WON'T DIE WINTERING.

Bees are doing nicely at this time—plenty of clover-bloom. I was out in the fields to-day, and saw them on all kinds of clover—alsike, white, and common red clover. Our bees work on the red clover from this time until frost, and many of them are only hybrids. I can not but smile when I see red-clover bees advertised as wintering without loss, since that class was originated, etc. Now, we have had them for over five years, and they die like other bees—sting us hard and as often as any.

We had a large swarm that came out and went directly to a hollow tree, without clustering; it was about a mile away. Fully three-fourths of the bees in this county died last winter. We left ours on summer stands without any protection, in single-walled hives, and lost over half.

LEE JOB.

Fillmore, Ind., June 15, 1885.

WHAT AILS THE BEES?

The bees in this part of the country wintered well—with the loss of hardly a single colony—if they had any protection. But since they commenced work this spring there has been a great fatality among them. At first we thought it was spring dwindling, but now we are half of the opinion that it must be poison of some kind. When the bee is first taken it rushes out, runs tumbling and rolling over the ground as if in great pain or trouble. After a minute or so it will settle down, commence rubbing its head with its fore-legs, then run out its tongue and wipe it off with its fore-legs, and then it will rub its hind-legs together, and so it will continue going, just from one of those motions to the other for a period of an hour or so, growing weaker and weaker, when it will die. Occasionally one will throw off its feces, fly away, and seem all right; but others do not. Their feces smell like sour honey. After the bee is dead its tongue is extruded, and the body drawn up rather than otherwise. In

your A B C book you mention that bees may be poisoned, but you do not state how they are affected. If you can tell us the cause of the trouble, or the remedy, if any, it may enable us to avoid more loss such as has already occurred. In some instances three swarms have been put into one; and in many, all of the bees have died.

C. D. WRIGHT.

Durango, Col., June 10, 1885.

Friend W., your bees are evidently poisoned by something they have gathered, or by some disease affecting them. Some of the symptoms you mention are strikingly like those of the nameless disease I have mentioned in the A B C book. I should try to find out what they are working on, to see, if possible, whether they have been gathering any thing that will account for it; also ascertain over how large a tract of country this malady extends. This may give you some clew to it.

THE WAY AN A B C SCHOLAR TRANSFERRED HIS BEES.

I will tell how I did it. I took a large piece of mosquito-bar, put it over a large hat, made arm-holes in it, tied it around my waist, put pants in top of boots, put on a pair of rubber gloves, and went to work. I pried off the side of a box hive. I had a good smoker, but didn't use it. I cut out the combs, and a friend of mine tied them in the frames. I think there was nearly 60 lbs. of honey in it, and somewhere near that of bees. There wasn't room to put your hands in for bees. My father said they would go to the woods next day, but they didn't. It took an hour and a half to do it. I filled seven frames of brood and honey, and there wasn't any room for more bees. These were transferred June 6, 1885. I looked at them Tuesday, the 9th, and cut off the strings; and they were doing finely. So much for a beginner.

Lockport, N. Y.

MYRON BAILEY.

Very well done, friend Myron; but if you did not use the smoker, you might have laid aside that big mosquito-bar veil also. The reason why you had so much honey and bees in the way was because you waited until June. If the operation had been performed in the time of fruit-bloom, as usually recommended, there would have been fewer bees and also less honey. However, you did pretty well as it was.

KEEPING BEES ON AN ISLAND; SOME SUGGESTIONS ABOUT WINTERING.

I am on an island of 600 acres and of course I have tried the bees here, and here is my experience, as short as I can give it. I came here in June, 1882; bought eleven full colonies; no surplus honey, no natural swarms; but fall found them in good shape to winter, and I did winter them without any loss—ten in Simplicity in cellar, one in chaff hive on summer stand (I Italianized all that year, 1882). June, 1883, found them in very good shape, ready for work. This year they made about 50 lbs. of surplus honey from five colonies; the other six I used for raising queens and dividing, selling some \$12 or \$15 worth. We had no fall flow of honey, and October found them almost destitute of stores, so I fed them up nicely until perfectly safe on this score, with sugar syrup, and placed them in cellar, nicely packed and ventilated (same number—11 colonies), Nov. 20, 1883. Now comes the point, and pride takes a fall. They all died but one, and that one was next to the

cellar-door; 8 died in March, 2 in April, and they died with their tongues right on the feed, and looking the same as in life, when standing sipping honey from a feeder—no disease of any kind that I could detect.

Now, what was the matter? Well, I am going to suggest, and see if you agree with me. I think the air was poisonous. I have now but two colonies. I shall try them on summer stands. I feel quite sure that I can not do much raising honey here, but I can raise queens, and good ones too, and have them purely mated. I am half a mile from "Maine" land; and I have noticed a great many times when I have been rowing across from the main land to the island when the wind was quite strong against the bees, they would fly heavily laden abreast of my boat, dropping lower and lower, until coming to the water, never to rise, so I feel that I lost thousands in this way.

L. S. SMITH.

West Gouldsboro, Me., Nov. 24, 1881.

Friend S., I should think, from what you say, that an island is not a very desirable place for keeping bees. In fact, there are times when a good many of them must be lost by falling into the water.—In regard to wintering, the fact that the one by the cellar-door lived, and the rest all died, seems to indicate, as you say, bad air, or not enough ventilation. Perhaps if you had a ventilator that would keep changing the air of the cellar, they would all have done as well as that one by the door.

HONEY-THIEVES.

I, like A. J. Kimmons, of Round Rock, Texas, am no specialist, although I take the greatest pleasure with my bees of any of the rest of my employments; i. e., general farming, and stock raising. In consequence of our excessive drought our bees scarcely made their own supplies. Last spring count, 44; increased to 74, and doubled back to 62, present number. I sold barely honey enough to buy a barrel of sugar, which I fed to the weak colonies.

A word now about thieves. I see by reading last GLEANINGS, that other localities are tormented by thieves as well as my own. I beg pardon; but while I should not like to kill a man (even a thief for stealing honey or any thing else), I still feel to demur from your only idea of education or evangelization; for we have a few (I am glad there are no more), that, according to Bible testimony, are "fools." They say in their hearts, "There is no God." Their only restraint is the fear of the law.

The two imported queens I got of you did good service; but the first one does much the better, and raises the best queens and bees. I shall want another in the spring.

ELIAS COLE.

Ashley, Ohio, Dec. 6, 1884.

Friend C., I think you misunderstood me. I would by no means do away with the law. I have never dreamed of advocating such a course. Send thieves to jail, by all means, as fast as we can get hold of them; but at the same time, do all in our power to prevent the necessity of law and jails, by education and evangelization. Almost every Sunday I meet with criminals in our county jail. I am sorry for the necessity of their being there; but yet I thank God every time I see one there, that we have been able to get hold of him and stop him in his folly. Only

yesterday afternoon at about this hour I was talking with a boy of eighteen years of age, who had been imprisoned a week under a charge of horse-stealing. The open saloon was at the bottom of it, as usual; and while I lamented that we could not have the saloon-keeper as well as the boy, I told him he ought to thank God for having thus brought him to a standstill in his folly. While intoxicated he took a horse he found by the side of the road—rode off six or eight miles, and traded it for another horse, getting \$35.00 to boot. The amount was just sufficient to send him to the penitentiary, for obtaining money under false pretenses, aside from the penitentiary crime of horse-stealing. He said he took the horse while under the influence of liquor; but after that influence wore off, he was afraid to take it back to the owner and ask his forgiveness; so he foolishly traded it off, and got arrested almost immediately. He was only eighteen years old, and the punishment seems terrible for the work of only a few hours. But this kind of horse-stealing has got to be so common that it would be dangerous if not wicked to let him go unpunished. We lament that we dare not take the risks of letting him off short of State's prison. But at the same time, the thought of that open saloon, all ready to send more boys after this one, should rouse every God-fearing man and woman to action.—It is often the case with queens as you state, friend C. In fact, we rarely find two of equal value in every respect.

A LITHOGRAPHIC LABEL THAT DOES NOT COST SO MUCH; ALSO SOMETHING IN REGARD TO LABELS AND CANS FOR EXTRACTED HONEY.

I struck a label last summer that is so handsome that I mail you one. It is the handsomest label suitable for honey that I have ever seen. I have not seen your extensive line of labels, and perhaps you may have some that surpass it. I obtained them from Gunn, Curtis & Co., color printers, 30 Hawley St., Boston, Mass. I bought 1000 for \$4.25, which seems to me to be very reasonable indeed. They are made to exactly cover a 1-qt. tin can, the same as the common tin fruit-cans. I put up honey in that shape, and retail cans at 50 cents each. I can buy the cans at a canning-factory at 3½ cts. each. After being soldered it makes the best package to sell to country customers that I know of. By cutting the label in two in the middle it makes a very fine one for 1 or 2 qt. cans, such as Mason's, or for pails or packages of any kind. A fine label will almost of itself sell any merchandise. I have taken much satisfaction in putting up honey in this neat way. If any of the bee-keeping friends would like to see one of the labels I will mail them one on receipt of a two-cent stamp.

As there has been a good deal of "spouting" lately as to how GLEANINGS should and should not be conducted, allow me to say that you furnish a good dollar's worth of "exclusive" bee business, and it is your privilege to give good measure and running over of that great spice of life—variety—if you desire to do so. JOHN F. WHITMORE.

Anita, Iowa, June 18, 1885.

Thanks for the sample you send us, friend W., and also for the offer to send one to beekeepers. The label is similar to the one we

sold largely before we got the Jones labels. I will explain to our readers that it is a beautifully colored lithographic label, made with proper blanks to be filled out so it will be suitable for either honey, syrup, or any other purpose; that is, the pictures on the labels have no direct reference to bee-keeping or any other special industry. The sample in question is filled out, evidently, at the label-factory; that is, the printing is put on before the varnish is put over the colors. This makes a very attractive label, and yet one that can not be soiled by honey or any thing else, for it can be washed off like oil cloth. A Jones label of similar size, printed to order, will cost \$6.50 per 1000. I suppose, from what you say, friend W., that you get these ready printed to order of the firm named, for only \$4.25 for a single thousand. If this is so, bee-keepers might afford to give them considerable trade. The prices you mention on tin cans are also low, our prices being for a one-quart can, \$3.75. I guess we shall have to make ours \$3.50, since you have told us we are above the market.

ANTS—A CAUTION.

I received the queen that you sent, in good order, and I was well pleased with her. It was the first Italian queen I ever saw. I was so afraid the bees would kill her I got three hatching combs (as you directed in the A B C book), and put them in a hive, and put her in with them, but I did not let her out of the cage until next morning, and I was glad I did not; for when I looked at them the next morning the combs were nearly covered with ants. I got them off and brought the bees into the house, and they are in here now. The ants killed all of them that hatched that night, so you see I nearly lost my queen. L. S. COCKE.

Ward's Mill, Ill., June 7, 1885.

Friend C., where combs or queens are taken away from the bees, and set down carelessly, ants are liable to do considerable damage. Many fine queens have been killed in this way.

FRIEND JACOB'S REPORT.

Here is my report for 1884, up to the present. I started with 11 swarms in box hives; increased to 19. I put all of my new swarms in frame hives. I got 127 lbs. of honey, for which I got 12¼c. I lost three swarms last winter. They were weak ones and should have been united. The rest of them are in good condition. I have one stand of Italians. It sent out a fine swarm the 24th day of May; the second swarm, the 5th of June. I have had only four swarms. Now I want to make bee-keeping pay. I love to work with them, but my pa and neighbors say I can't. They say that there are too many bees in this country now. I tell them that is why I think this to be a good bee-range. We have poplar, white clover, and sourwood, and lots of it too. It is true, that every farmer has bees, from one to ten stands, all in box hives.

Here I had to stop writing to hive my third swarm of Italians—two queens in this swarm. This is three swarms and three extra queens that I have got from this hive, besides one that was killed in the second swarm. JACOB W. MILLER.

Daysville, Ky., June 7, 1885.

DOOLITTLE'S WAY OF MAKING NUCLEI.

I tried friend Doolittle's way of making nuclei, and at first I made a failure of it, as they killed the queen, and nearly half the bees died. I made them fill themselves well with honey, but did not think of putting candy in, which did all the mischief. Next time I put candy in, and it worked all right, and I thank friend D. for bringing it up. Some of the bees will return, but not many. Of course, the 1-lb. package for sending away bees by the pound will do for a box to put them in. You presume friend D. puts his best queen in, but I am certain I would not do so.

SHIPPING BEES WITHOUT A QUEEN OR BROOD.

What is your experience in shipping bees by the pound, without a queen or brood? At a loss of five lbs., I do not think it is a good way of putting them up, and I am quite certain it is not good for them to be confined in those small packages without a queen, as they tear around till they are very nearly exhausted or worn out; but just put a queen or a frame of brood in, and they seem to enjoy the trip hugely; and, again, I think the 1-lb. packages as you make them are too small for a pound without a queen. Why not put them up as friend Foster, of Iowa does? C. WECKESSER.

Marshallville, O., June 12, 1885.

We often ship bees without queens, friend W., and I have not been able to discover that they did worse without a queen than with, although I may be mistaken. I know they sometimes tear around until they get themselves quite exhausted, and I presume kill themselves, many of them, by fright or worry; but I was not aware that they did this any worse when queenless, although I am aware that the presence of a queen or a little unsealed brood exercises a very marked influence in the way of pacifying bees when they get in an uproar.—In regard to the one-pound packages being too small, we have frequently sent 1½ lbs. in a package, and had them go safely, and it is only during the extremely hot weather that as much room is needed as we allow. Perhaps you measured a pound of bees when their bodies contained no honey. If so, a pound makes a good many. During the honey season, each bee contains more or less honey, and we can not very well put them up in any other condition. We do not remember that we ever heard how friend Foster does put up bees. Won't you tell us? I know he sells bees very low, and makes successful shipments.

A BEE-KEEPER IN TROUBLE AGAIN.

I have four swarms of bees out of eleven I had in the fall. I should like to sell three of them, but I don't know how I can get them to you. There are two double hives and one single one. I think they must be full of honey, as they have been getting it from the other hives where bees have frozen, and that, perhaps, is what makes them so cross and overbearing. Is not that the nature of some of the human kind—the more stores they heap up, the more unfeeling and quarrelsome they are?

But, about these bees. Can't you send an expert, or come yourself, and fix these bees in a shape so they can be handled or taken away out of my sight and hearing? I should like to see you walk up and conquer these savage little insects. I am at this writing smarting under their wounds. They take

me under my hat-rim on the back of my head, and I don't wish to have those bumps grow any more. If you can give me as much honey as you think there is in the combs, and pay for the bees, I shall be more than satisfied. Now, please come and get the bees; or if you can't do that, drop a card with some good advice. IRA BENNETT.

Windfall, Medina Co., O.

Friend B., it seems to me you have been handling your bees at unseasonable times again—possibly just during a gap between fruit-blossom and white clover. We should be glad to take your bees off your hands, because we need them now; but if you wait just a few days I think you will find they are peaceable and amiable again, even if they are hybrids. You want to learn to take bees as well as human beings on their best side; and when you find them spoiling for a fight, just wait until some other day, and then you will, in all probability, be able to get along without these unpleasant differences and bumps, where no more bumps are needed.

HOW FAR MUST THE OLD STOCK BE MOVED IN MAKING AN ARTIFICIAL COLONY? ETC.

Will you please tell me whether the bees would stay in a new hive where you had made an artificial swarm, and gave them a new queen, if I only move the parent stock to the opposite side of the bee-house? I had figwort and spider-plant seed sprout in less than a week, by making a small hot-bed and covering it with glass. The spider plants were large enough to set out in two weeks. My bees are in fine condition, and building up very fast. They are gathering honey very fast from locust.

FRED W. CRANSTON.

Woodstock, Ohio, June 5, 1885.

We do not understand your term "bee-house," friend C. If you mean honey apiary, moving your colony to the opposite side would do very nicely, I think.—If you had spider plants ready to transplant in two weeks from the seed, you certainly did well. We have had a great deal of trouble in transplanting the spider plants this past season, although it usually seems very hardy.

VALUE OF A COMB FILLED WITH POLLEN.

Will you please tell me which is worth the most to a swarm of bees—a nice card of comb which is three-fourths full of pollen, or a sheet of foundation? Will bees clean the pollen from combs, if hived on such? MRS. JENNIE COLLINS.

Romeo, Mich., June 6, 1885.

The answer to your query will depend on circumstances. If bees have their combs already full of pollen, a comb three-fourths filled with pollen would be no advantage, but, rather, a detriment. On the contrary, when they are short of pollen, as bees are here almost invariably in the spring, a comb of pollen would be a very great advantage to them.—I should say, that a comb of good pollen is worth a good deal more than a sheet of fdn., on an average. If the bees are hived on combs containing too much pollen, they will usually use it all up in brood-rearing. I can not tell, though, what they would do in case it were not needed for brood-rearing. Very old pollen they sometimes take from the cells and throw it out from the entrance.

AN OREGON BEE-TREE.

We clip the following from the *Portland News*:

TEN FEET OF PURE HONEY.

A short time ago Samuel, Asa, and Joe Holaday, of Scappoose, took a trip over to the Lewiston River, in order to look into the resources of that region. They found it a most beautiful country, and one that offers many inducements to settlers. The part visited lies off in the direction of Mount St. Helena, and is composed of both timber land and fine open tracts, which abound in game, large and small. While encamped on the river they discovered an object that was novel and interesting as it is beautiful and striking. In their rambles through the pine wood they suddenly came upon a fallen tree across the path, which, on inspection, they found to be hollow. Through a knot-hole they could see something white, and at once began to investigate. They sawed into the log, and were surprised to find that the whole interior of the log was filled solidly with honey. They at once brought from their camp some of their vessels to fill with this sweetest of all nature's productions. Their buckets and pans were soon filled. Then they sawed off another length of the log, and found it still solid with honey. This they repeated, and took from it honey until they opened up ten feet of pure, lovely honey, which yielded a comb that was in many places four inches thick. Of this find they carried away 180 pounds, which they declared was the finest they ever tasted, being far richer than the tame honey which they produce.

GOOD PROSPECT AHEAD FOR BASSWOOD.

Our prospects for a honey flow down in this section are not very promising, as about all the old clover crop of last year was frozen out the past winter, but with the favorable weather of the last two weeks the basswood, or linden, will keep them busy two or three weeks, as I have never seen as good a show for bloom since it has come under my notice. Our creek bottoms are covered with the trees in every direction; and as bees are so few there will be a good many trees untouched. I came out in the spring with 5 prime and 3 weak colonies; have had 4 good natural swarms. The first came off the 15th day of May; the last, about the 5th of June, and I have built up my weak stock strong enough to store in boxes. From one-half pint of bees to a chaff hive full is pretty fast building up. The yellowest and nicest queen I have does not raise as fine queens and workers as some very dark ones I have, as I get my best queens from the medium-dark queens.

Dennison, O., June 22, 1885.

C. J. HILL.

We are happy to report basswood-trees in our vicinity are also full of buds, ready to blossom in a few days.

A SUGGESTION FROM OUR GOOD FRIEND GEO. B. PETERS, AS TO THE CONTENTS OF GLEANINGS.

As there seems to be a disposition among the patrons of your excellent journal to *advise* you as to the subjects most proper to be treated in your issues, and as you seem to be feeling for the opinions of such patrons, I will, with diffidence, say that I think a bee-journal should treat of bees and their relations to other rural pursuits only, leaving to the professed divine to publish a newspaper on his theme proper, if one should be so disposed. I think the bee part of GLEANINGS is sought after with avidity by the apicultural patient, and the religious part read only by those who do not take a religious paper at all, or perhaps have no facilities for attending church. I think religion and politics should be eternally severed—also religion from the legal profession—that is, a mixing of the respective journalist, and I think bee-matters, and those things intended as a *salvo* for the ills of human nature,

should be sundered; believing that each one has importance enough to be dignified by its own special journal. Now I see you advance high authority on both sides of the question; and in your dilemma you invoke divine assistance to show you the course you are to pursue. Among your advisers is the name of Prof. Cook, advocating. Now, while I have great respect for friend Cook as bee-authority, I have none for his attempt to chalk out the course of a mixed-journal—that is, he is good authority on bees, but very poor on divine matters. Would it not be better to run two journals—one for apiculture and one especially for the faithful? In the present summing-up of testimony, I must side with friend Hutchinson and those of his opinion.

GEO. B. PETERS.

Council Bend, Ark., June 19, 1885.

Thank you, friend Peters, for your kind and frank letter; but I am sorry to see you for once with the small minority. I do not remember now of more than three individuals who have agreed with friend Hutchinson in his remarks. You are one of them, and the brother who first called the matter up, and friend Clarke, are the others; while those who have petitioned most vehemently for about the same variety in GLEANINGS it has been giving, are numbered by the hundreds. Perhaps I am at fault in letting it appear that I was in a "dilemma." I have been in no dilemma at all; for since I decided to seek first the kingdom of God and his righteousness, I have never, I may say, hardly *thought* of such a thing as turning back. I am asking God's blessing daily, not only in regard to what matter shall be used for GLEANINGS, but on our bee-keeping industry, and every thing pertaining to it. I do not mean to say by the above that I have always chosen just the wisest course between two extremes; for to err is but human, and I thank you for your kind letter, because it may help me to be more careful in some respects than I have been. I have thought of two journals; but one is all my strength will probably ever be able to compass; and if God gives me strength to do that one well, I shall be thankful.

RAISING FIGWORT AND SPIDER PLANTS BY COVERING THE SEEDS WITH MOSS.

I am one of your A B C scholars, and therefore I am somewhat interested in bee culture. Bees in this section of the country have wintered badly. Some have lost all; and what bees there are are mostly in log gums, except ours. We use your Simplicity hives. We had 15 stands last fall, but we have only 4 this spring—one strong and three weak ones. We purchased one ounce of figwort and spider-plant seeds from you this spring. We sowed some of the seeds in open ground, and some in boxes. About the first of May they were just coming up, when I saw the directions in GLEANINGS for covering with moss. I made a box 12 inches square and 4 inches deep. I filled it two-thirds full of dirt, and sowed the seeds thickly, and put an inch of moss over them, and put a pane of glass over the box. In just one week they were up. I think if the friends will do as I have done, they will have no more trouble about sowing the seeds.

This is a great country for white clover, and we have a few basswood-trees. The bees are gathering lots of honey from the locust-trees now. I think

you might tell us how to set out these figwort and spider plants—how far apart, and when, and all about it.

W. A. LOWER.

Maywood, Lewis Co., Mo., June 16, 1885.

Friend L., when the little plants come up very thickly, we take them up when they begin to have the second set of leaves, and plant them about an inch apart, in good soft ground in the greenhouse, or outdoors as soon as the weather will admit. Here they stand until they are three or four inches high, and then we plant them in the open ground about as far apart as hills of corn. The cultivation afterward is just about the same as for corn.

A CALIFORNIA BEE-KEEPER WITH 400 COLONIES.

I received the package of GLEANINGS a few days ago, and I was just delighted with them. The weather down here is awfully dry, but still my bees are working on very well. I have about 400 colonies in box hives, invented by Mr. J. S. Harbison, of San Diego, Cal. The section boxes used here by almost all the bee-men of this county are different from those in your catalogue. They contain about 2 lbs. of honey, and are put together eight in number, and fastened so that each one can be taken apart. We pack four such boxes in a case, or 32 sections, making in all about 70 lbs. to the case. I am glad to see that GLEANINGS comes out twice a month instead of once.

H. C. NORTH.

Engineer Springs, San Diego Co., Cal., June 15.

THE SEASON OF 1885.

Bees have done nothing but raise brood. Out of 44 good strong stocks, most of them *extra* strong, I have had two swarms; and they have on an average about 2 lbs. of honey to the hive, and no prospect that they will more than make a living for a few days, as clover is dried up on account of the drought. If we have rain soon we hope for a fall harvest, which generally commences about the 10th to the 15th of August. We had five days in fruit-bloom in which bees worked and gained several pounds per hive; since then two or three days they have gathered a little more than a living. With full honey selling in New York as low as 7 cts. per pound for box honey, it looks rather discouraging, and beginners should examine well before investing largely, as it is *very* difficult to sell out, without loss.

JOHN B. CASE.

Baptisttown, N. J., June 22, 1885.

Friend C., I do not believe that nice comb honey in one-pound sections has ever been sold at the price you mention in New York city. These discouraging reports, when sifted down, almost invariably prove to be the result of careless management.—We are surprised to hear that you have been troubled with drought. Here in Ohio, and, in fact, from most points where reports have come in, there has been almost a superabundance of rain—in fact, so much rain, that some complaint has been made that the honey was washed out of the clover before the bees had time to gather it.

WAS IT GOOD LUCK?

I bought 5 colonies of bees from D. L. Carpenter, of Seneca, Illinois, last May; three in your 2-story chaff hives, and two in what he called your Simplicity hives. The bees increased so that I went into winter quarters with 14 colonies; went through

the winter all right; lost one this spring by robbing, and two by dwindling; they have bred up well, and I think most of them are about ready to swarm. I had one swarm on Sunday. All but three were wintered in Simplicity hives packed with leaves. I think I had good luck, as three of my neighbors lost nearly all of theirs. One lost all, 25; another lost 13 out of 14; another 21 out of 22; and the oldest bee-keeper, about three miles from me, lost 50 out of 56; of 50 put in cellar, one saved six; six on summer stands lost all. Mine were all wintered on summer stands. Don't you think I had good luck with mine?

JESSE BRADY.

Little Rock, Ill., June 16, 1885.

HUMBAGES AND SWINDLES PERTAINING TO BEE CULTURE.

MRS. COTTON, AGAIN.

WE publish the following, just as it came to us.

Some time ago I got a paper from a voo-man by ze name of Lizzy Cotton, and she said would sell me a hive that bees would make two hundred pounds honey of; so I sent ze moneys; it was 3 dollers, and I paid one dollar and fifteen cents for ze expresman on it, and it was nodding boot a leetle hive, so big az 6 inches one way 24 inches de odder, ant she sent me a great big paber. I send him to you. Vat shall I do now? My moneys gon out, no hive but ze leedle bit of a hive, not so big as our coffy-mill. Mine nabor says you will make her sent it back to me, for I am poor, mit lots of leedle babies to eat honey. Mr. Root, tell us what to do, then I can read it in that leedle book mine nabor calls GLEANINGS, vat you sent out.

HERR CLABBERDEBOSH.

Aytalan, Wis., June 16, 1885.

My good friend, I am much obliged to your neighbor for his confidence in my ability to straighten up wrongs in bee culture; but Mrs. Cotton is a woman, and I can not do any thing with her, any more than to publish your letter as a warning to others who might be likely to send to her. Where a man is in business, and advertises implements in bee culture that do not give satisfaction, we can generally make him do the fair thing by telling him he will have to be published if he does not make his transactions satisfactory. But Mrs. Cotton evidently does not care whether her wares give satisfaction or not.

MRS. COTTON TAKES \$20.00 FROM A POOR WOMAN WITH BUT ONE ARM, AND THEN SENDS HER A PART OF A HIVE CONTAINING FEW BEES AND NO QUEEN.

Last week I was sent for by a lady acquaintance, who lives about half a mile from me, to "look at a colony of bees" that she had bought of Mrs. Cotton in one of Mrs. C.'s "Controllable" hives. The lady had received the bees ten days before, but had delayed having them examined till the expiration of that time, in accordance with Mrs. Cotton's instructions. An examination showed three frames with fair combs, two with inferior combs, mended and fastened in the frames with sticks, and one frame occupied with a sheet of foundation. I found bees enough for a small two-frame nucleus; no unsealed brood, and about as much sealed brood as would

occupy one side of a Langstroth frame. I also found four small queen-cells, sealed, and one uncapped, from which a queen had emerged, and one young queen about 12 hours old. I found the two side cases and a sample box each of the sizes Mrs. Cotton uses; and, of course, I found the wonderful Controllable Cotton hive without any cap, and my unfortunate lady-friend, who has but one arm, found twenty good dollars to pay Mrs. Cotton for all these "finds," and \$3.40 to pay express charges, and sixty cents to pay for cap for hive; and if that young queen gets lost, the lady will soon find that, without kind neighbors who can keep bees, but perhaps can not write books or invent wonderful hives, she will have, for her \$24 investment, little besides the wonderful Cotton hive and a few combs of no great value. If you think the above in relation to Mrs. Cotton's shameful treatment of this lady will be of service as a warning to others, you will please give it publication. JAMES KNOX.

Quincy, Ill., June 15, 1885.

The above verifies what several of our subscribers have before suggested, that Mrs. Cotton sends out a hive with nothing but queen-cells instead of a queen, and this, too, where she gets \$20.00 for what her advertisement would lead any one to suppose would be a full colony of Italian bees, and in a finished and complete hive.

NOTES AND QUERIES.

THE honey crop threatens to be the greatest failure ever known in this State. The ordinary white-clover season is nearly past, but our bees have found scarcely enough white clover to be self-sustaining. The poplar, or tulip, fortunately, yielded unusually, and enough is stored, I think, to insure successful wintering without feeding. S. W. MORRISON, M. D.

Oxford, Chester Co., Pa., June 20, 1885.

THE NEW CARP-BOOK.

Carp A B C received, and I went down to the carp-pond and witnessed the hatching of thousands of eggs. I shall soon have all the fish I can eat, and some for an occasional fish picnic.

Dresden, Texas, June 16, 1885. B. F. CARROLL.

RECIPE FOR HONEY-CAKE.

Will you allow me to make a little improvement on my recipe for honey-cake, as follows? Two cups of honey, one cup of sour cream, four eggs; flavor with ginger and cloves or allspice, as preferred. Warm the honey enough to make it thin; mix soft.

MRS. L. M. HARDISON.

Santa Paula, Cal., May 8, 1885.

NEW HONEY.

I am a young man 23 years old. I have commenced raising bees. I began this spring with three hives of bees. They were blacks. I have seven hives now. I have taken 215 lbs. of honey this year from the three hives I began with, all in comb, and one of them is filled again. I took the honey from them the 23d of May. I got 50 lbs. at that early date, and they have it all new and white again. I examined them yesterday, and found the new comb all sealed again. I find that there is profit in bee-keeping. J. W. TAYLOR.

Ozan, Ark., June 14, 1885.

HONEY-DEW IN 1885.

I will say that there is an abundance of honey-dew to be gathered here now in the woods; but for reasons best known to themselves the bees do not notice it yet, for which we are truly thankful, and hope they will continue to let it remain. Sweetness "wasted on the desert air." Bees strong, and prospects good for white clover. M. W. SHEPHERD.

Rochester, Lorain Co., O.

BROOD AND POLLEN IN THE SECTION BOXES.

Our bees are putting brood and pollen in the section boxes. What is the cause?

Lower Salem, O.

SYLVESTER BABSON.

[This matter has been very fully discussed in our back numbers, and also in the A B C book. Perforated zinc honey-boards, perforated wood honey-boards, slotted honey-boards like Heddon's, the use of separators, and a great many other devices are used to discourage the queen from going up into the sections. Considerable depends upon the construction of the hive, but I believe there is not much trouble of this kind.]

I bought one hive in the spring of 1884, and one in July; also one in November, and all lived through the winter. Two were in box hives, and I transferred them and gave them Italian queens, and I divided my strongest hive on the first of this month, and all are doing well. We have a grand honey-flow from the locust. Bees all died, or about all, in this part of the county this winter and spring.

CHARLES E. HARDESTY.

Conotton, Harrison Co., O., June 8, 1885.

As I have been pretty busy this spring I have not had much time to write. Well, I lost all of my bees (6 colonies) last winter and spring; four from dysentery, and two from spring dwindling, and now all together I have spent \$45.00, and have sold but \$5.00 worth of honey and wax. Now I have got on hand ten Simplicity hives and fixtures, besides 50 empty combs. I am not going to give up yet, just as I am beginning to get used to bee-keeping, and have got the fixtures. Our strawberries are getting ripe. We sold four bushels Friday last. C. W. BOND.

Jackson, Mich., June 22, 1885.

NEW SWARMS GOING INTO EMPTY HIVES.

Speaking about swarms going into empty hives that are standing around, a few years ago when Mr. George Haven kept bees he had two come out at about the same time, and alight separate. He carried a hive, and put it down near one swarm, and then went to live the other; and when he got back to his hive the bees had gone into it. I think he said the empty hive was a rod or more off. I had in fall, 70; spring, 40; have 56 good ones now, and increasing rapidly. JOHN CROOFOOT.

Bloomington, Mich., June 16, 1885.

Do bees go to sleep regularly?

[Bees do not go to sleep at all, friend H., that we know of, unless it is in the winter time. It is pretty certain that they do not sleep "regularly," if they sleep at all.]

Are black bees more likely to abscond to the forests than Italians?

[I do not believe the black bees are any more likely to go to the forests; but if any thing I should say it is the other way.]

Will packing chaff hives with rags be better for wintering? H. A. HYLE.

Redwood, N. Y., June 1, 1885.

[I do not believe I should like rags for packing as well as clean soft chaff.]

FRAMES OF BROOD WITH OR WITHOUT BEES, FOR BUILDING UP.

ALSO SOMETHING ABOUT BUYING UNTESTED QUEENS.

IN the A B C book you speak of building up colonies by taking frames of *bees* and brood from *different* hives, and putting them together, etc. Now, in my short experience with bees (this is my second year) if I wanted to build up a weak colony I would always shake off all the *bees*, and just carry the frame of brood to the weaker hive. I have always been afraid of making a rumpus, or starting a fight, by putting even a few strange bees in the hive. If I understand right, such care was not necessary, only, of course, I should not take my old queen along. Please make it a little plainer.

I have got untested queens of you twice this spring—the first in the beginning of May, with one-half pound of bees. I got them started all right, but the queen was no good. I helped them along with brood from other hives, and the queen laid some, then she got to laying, as Mr. Garwood tells in the June GLEANINGS, two or three in a cell—in the bottom, on one side, and near the bottom on the sides. I didn't understand, but left her alone, and about the 1st of June all at once she was gone. I do not know where, and they had started queen-cells, and have a young queen now. I think the old one was about played out when I received her—one you had got from the South, probably in the spring rush. The other queen which I received about the 25th of May, I think is first rate, but dark.

S. L. LOPAR, 9-6-0.

Indianola, Iowa, June 22, 1885.

Friend L., I think you will find that we describe how to employ both methods, in the A B C book. Where you want to strengthen a weak colony, get a comb containing *hatching* brood, and put it in your colony to be strengthened, without bees. The reason why you shake off the bees is, that they might kill the queen of the weak colony. The only difficulty in this plan is in finding the comb just right for your weak colonies. If it contains too much unsealed brood, the bees of the weak colony may not be able to nurse it well, and this will occasion loss. Or if it contains more sealed brood than the weak colony can cover and take care of during the cool weather, loss might ensue. What you want is a comb containing a moderate patch of brood, all of it sealed, and some of it hatching. Shake off all the bees, and you have got it exactly. The other plan is where you want a nucleus. Take the comb—brood, bees, and all—from say three or four different hives. Put them all in together in a new hive, or nucleus hive, and there will rarely be any disagreement; for none of them are at home, and they soon get mixed up so that they do not know which is which. As soon as they settle down peaceably together, and start queen-cells, you can usually introduce the queen without any shaking, or they will take nicely to a queen-cell.

Friend L., you bought two untested queens—one good and one poor one. The good one is worth all you paid for both of them; but as a rule I should say that nine out of ten prove to be good prolific queens. I think

your remark unkind and uncharitable, both to myself and the friends in the South, when you intimate that any of us sent you an old queen. I know it is very common for those who make a purchase, to declare the queen is old or unfertilized, if she happens to fail or die; and I am obliged to remind our customers very often, that queens are no exception to the rest of creation; and after a long trip through the mails, it ought not to be surprising that some should fail, or prove to be short-lived. We have but little opportunity for judging of the age of a queen-bee by her looks; therefore too many of us seem to jump at the conclusion that queens never die unless from old age, which is not true of any kind of animated nature. Perhaps, friend L., you intended what you said for pleasantry. None of our employes ever let a queen go to a customer until she is laying, and we have every reason to believe she is all right; and I have good reason to think that those in the South, from whom I purchased queens, are equally conscientious. Untested queens are, of course, sent without any guarantee; but for all that, the trade increases largely in them year after year. This season, I should say that 90 per cent of all our orders for queens are for untested, even though a few have turned out badly, like the one mentioned. Where the queen never lays at all, we have been in the habit of replacing her; but where she commences to lay, and soon fails, the purchaser has to take the same chances that we do in buying.

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

A. I. ROOT,

EDITOR AND PUBLISHER,
MEDINA, O.

TERMS: \$1.00 PER YEAR, POSTPAID.

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, JULY 1, 1885.

But God hath chosen the foolish things of the world to confound the wise; and God hath chosen the weak things of the world to confound the things which are mighty.—1. COR. 1:27.

We have to-day, June 27, 1885, 6404 sub. scribers.

REPORTS WANTED.

We should be glad to know how those having reversible frames like them thus far.

BUCKWHEAT WANTED.

If any of our friends have any of the common gray or silverhull for sale, will they please let us know how many bushels, and what they will take for it?

WATERBURY WATCHES.

WHILE still more important improvements have been made in these watches, the price is still lower. We can now send GLEANINGS for one year to every one who will purchase a watch at the regular price, \$3.50. Where you have recently paid us a dollar for

GLEANINGS, you may have the watch for \$2.50. Or if your time is nearly out, you can have GLEANINGS for another year for every \$3.50 you send us for a Waterbury watch. Where the purchaser does not want GLEANINGS at all, the price will be \$3.00; two watches, \$5.75, or five for \$12.50.

BEEWAX AND FOUNDATION.

For the present we can not offer over 20 cts. cash for wax, or 25 cts. in trade. The reason is, we have so large a stock on hand, and there is so little demand for foundation. We will also give a discount of 10 per cent from figures in our price list for all orders for foundation received after July 1.

MR. LANGSTROTH.

Our old friend is feeling so much better that we have the promise of something valuable from his pen for our next issue, no preventing providence. In a letter from him dated June 26, we find the following extract:

It will surprise many to learn that, more than a hundred years ago, some writers on bee culture attributed dysentery to the eating of pollen, while others thought it was caused by the want of sufficient pollen.

A LITTLE BOOK ON FOUL BROOD.

We have just received a little book entitled, "Foul Brood: Its Management and Cure," by D. A. Jones. In the book, friend Jones considers chilled brood, neglected brood, overheated brood, drowned brood, dead brood, dead larvae—all these as well as foul brood. We can furnish it from this office for 10 cts.; by mail, 11 cts. Although friend Jones does think that foul brood may sometimes be generated spontaneously, we think the little book is well worth the money.

ANOTHER JOB LOT OF WIRE CLOTH.

We are unable to get any more at the very low price of 1½ cts. per square foot, but we have secured a splendid lot of regular goods of the following widths: 24, 26, 28, 30, 32, 34, 36, 40, 42, and 46 inches, which is put up as follows:

12½ rolls of 200 s. f. each, 2 of 36, 1 each of 40, 120, 180 s. f.
24 4 rolls of 216 s. f. each, 1 each of 195, 87, 69 s. f.
28 16 rolls of 233 s. f. each, 1 each of 46, 116, 70, 240 s. f.
30 16 rolls of 250 s. f. each, 1 each of 158, 125, 30, 225, 2 of 60 s. f.
32 1 roll of 94 square feet.
34 5 rolls of 283 s. f. each, 1 each of 62, 113, 198 square feet.
36 11 rolls of 300 s. f. each, 3 of 75, 1 each of 60, 225, 120, 150, 210.
40 1 roll of 235 square feet.
42 1 roll of 350 square feet.
46 1 roll of 192 square feet.

The above we can sell at 1½ cts per square foot. The manufacturers have given us these remarkably low figures in consideration of the very large orders we have been giving them for a year past. I tell you, my friends, when the bee-keepers of the world unite together in purchasing a certain line of goods, it takes a pretty big factory to supply them.

QUEENS MISSING IN SHIPMENTS.

PROBABLY none of the friends who sell queens, bees, and nuclei, have been very long in the business before more or less complaints came that certain colonies or pounds of bees contained no queen. The question then arises, Did the shipper omit to put in the queens, or did the receivers let her get away by some accident after the package was received? It should be borne in mind, in deciding such questions, that no one is hardly ever safe in declaring there was no queen among the bees, simply because he could not find her. The best of us frequently look in vain for a queen, and sometimes in a comparatively small body of bees, and yet she is there all the while. The universally accepted and plain way of settling the matter beyond dispute is to look for queen-cells. With a nucleus

or a hive of bees, the matter is easily settled. If no queen was put in when the bees were started, queen-cells will always be found at the time they are received, and the purchaser should, of course, write back at once, "You either omitted to put a queen with my bees, or she was lost by some accident about the time of shipment, for queen-cells were built, and well along when the package was first opened." With a pound or half a pound of bees, the matter is not so easily settled; but as such packages of bees should always be let loose on a comb of sealed brood, the absence of the queen should be settled decisively within 24 hours: for if no queen is present they will start cells on the brood given them, in about that length of time. A good many of the friends who receive bees are inexperienced, and sometimes thoughtless, in writing back to the shipper that he did not send any queen, for the simple reason they looked and did not find her. Now, unless this matter of queen-cells is understood and plainly mentioned, I should say the purchaser is not entitled to another queen free of charge.

HOW THOSE STRAWBERRIES TURNED OUT.

WELL, my friends, they turned out magnificently, if that is the word for it. Our strawberry-patch was worth all it cost, just to see the whole family—Maude, Connie, Caddie, clear down to Huber, mamma included—and all as busy as they could be, gathering the ruddy treasures. There is one thing about this strawberry business that astonishes me; and that is, that people have been lazily sleeping over the matter, as it were, until almost clear up to this year of 1885, before they knew what a feast and what a "picnic" we could all of us have with so little exertion. Strawberries have sold in our market as low as five cents a quart, and loads and loads of them have been consumed. But it did not matter to us what price they were up street; we had them at home of our own raising, and they were ahead of any that could be bought in the market. Now, one more thing surprises me, and that is, that people do not with one accord give a great big vote of thanks to the man who first gave us the Sharpless strawberry. Why, on each side of our row of Sharpless plants, the ground is covered with great "chunks" of luscious fruit, as juicy and as delicious as one of the finest pears, and you do not need to wait until they are real ripe either. As soon as you can see one of these great berries colored, you may be sure it is good to eat, and without any sugar. I never ate any fruit in my life that I so thoroughly enjoyed as these great awkward chunks of berries—berries so large that you could take a great big bite, and then look at the beautiful, juicy, ruby flesh on the inside of a berry where you have bitten it. Huber finds it a hard matter to get some of them into his mouth, so he can get a good square bite. Perhaps the reason why our Sharpless berries have been superior to any of the other varieties is, that they occupied the double furrow in the center of our bed. You will remember, perhaps, what I told you about it last fall—the way we plowed and harrowed and subsoiled that piece of ground, and then covered it three inches deep with the best old well-decomposed stable manure we could find. Well, I tell you it was a paying investment. All the Sharpless berries we had to sell brought 15 cts. a quart, while the common varieties sold at from 5 to 8 cents. Our best day we picked 37 quarts.

THE A B C OF CARP CULTURE.

By a misunderstanding between the author and publisher, we fixed the price on our carp-book at 40 cts., when it should have been 50 cts., by mail postpaid. Hereafter please remember that the price is 50 cts., and it is a good large book (104 pages and full of pictures) even then, for the money. We think it will be an exceedingly difficult matter for any person to ask an intelligent question concerning carp culture, which is not fully answered in this book.

A FRIEND asks how to get a swarm of bees to go into a chaff hive. He says the entrance is so small that he has tried two swarms, and could not get either of them in. Our friend could have managed it very easily by shaking the swarm, or pouring them into the top of the hive. He would have to get them down to the brood-frames then, and use the enamel sheet or honey-board, or they would be very liable to commence their combs on the cover. We have never had any trouble by making them go in at the entrance, although of course it would take a little longer than if we could enlarge the entrance to any desired extent, as we can with the Simplicity hive.

IMPORTANCE OF SENDING QUEENS PROMPTLY.

We have been at times during the past month as much as a week behind on our orders for untested queens; but the orders have been so much more numerous than we ever knew them before, that we were not prepared for such a trade. It has hurt our business, I know; and I am resolved that, if possible, we will not have this happen next season. As an illustration of the trouble that delays make on this kind of merchandise, I make the following extract from a letter of complaint: "I paid — for three queens April 22, and walked fifty miles to the postoffice to receive them." Now, we hardly think that the above friend walked fifty miles expressly for the queens; but if he had to wait just 60 days, it may have been pretty near it. Do you see the point, brethren? The queen-breeder mentioned above would have to pay his customer five or ten dollars, perhaps, for the annoyance and bother he has caused.

LOTS OF THINGS TO BE THANKFUL FOR.

HERE at our house we are having sixteen long hours of daylight every day, sunshine in unlimited quantities, and a great abundance of rain just about as soon as somebody begins to talk about dry weather. On top of it all, your humble servant is enjoying perhaps the best health and spirits he has ever known. Do you want to know how he got it? Well, a good deal of it came from digging in the soft black dirt down by the carp-pond every morning, just a little before sunrise. That is where our cabbage-plants, sweet corn, Hubbard squashes, etc., are, and there are two coops of young Brahma chickens down there that help every morning by chasing bugs off the cabbages. You see, when I get off down there so early, the office is all left behind me—there is not even anybody around to ask questions; and there all alone with the chickens, plants, and God, is it any wonder that I get happy and *well*? When it comes breakfast time, I never need urging to eat; and what I eat gives me strength, so that I manage the duties of the day without much trouble or fatigue—especially if I can play with the cultivator and other farming tools about every alternate hour in the day.

KIND WORDS FROM OUR CUSTOMERS.

The 50 lbs. of comb fdn. came promptly, and it is very nice. Many thanks for promptness. Express charges were moderate enough. W. S. POWDER.
Groesbeck, Ohio.

Your last sections were nice, and also your section foundation. This is why I sent to you also this time. I can get my goods nearer home, but your fdn. was nicer than some years ago. H. M. MOYER.
Hill Church, Pa., May 30, 1885.

GOOD TIME ALL ROUND.

The untested queen you sent me the 21st was received the 22nd, introduced morning of 23d; liberated at evening, 24th; is laying this 25th. Many thanks for prompt shipment. C. A. RICKETSON.
Quincy, Mich., May 25, 1885.

OUR 75-CENT TELEPHONES.

The telephone received from you is put up; and as a proof that it gives satisfaction, you will please send me three more. JOS. LOGEROT.
Ledonia, Tex., May 19, 1885.

ONE REASON WHY FDN. MILLS DO NOT WORK SOMETIMES.

The mill works nicely. I find my trouble last year was entirely due to the impurity of the wax. You may remember what a nuisance I was to you. Fort Wayne, Ind., May 22, 1885. ROLAND HOLMES.

MOORE'S CRATE FOR THE SIMPLICITY HIVE.

I got the goods all right, and must return you and your clerks my thanks. I am well pleased with all. I like those Moore's crates for Simp. hives very much. I have some nearly full now. Bees are doing very well; I had one swarm, but don't think there will be many. I lost very few in winter. Shepherd, Ill., June 4, 1885. WM. ROUSE.

KIND WORDS FOR THE A B C BOOK.

I sent a few days since through Mr. Weaver, of this place, for your A B C book, and to say I am delighted hardly expresses it. I am amused and pleased, too, with the way—the common-sense way—in which you ———. I don't know but your book may work a great change in my pursuits ultimately. I like the spirit of your book. Rev. C. E. CLINE.

Emmetsburg, Iowa, June 18, 1885.

STRAIGHT MEN.

Your account is, I presume, all O. K. I never keep an account when I deal with *straight* men, and I feel assured that you are. W. VERMILLION.
Bradford, Ohio, May 13, 1885.

[Thanks for your kind words, friend V.; but I do not quite approve of your way of doing. I would much rather that everybody who deals with me should keep account, and look carefully to see that no mistakes are made.]

AN ENTHUSIASTIC BEE-HUNTER.

The smokers were received in tiptop order in due course of mail, and now we request you to send one Clark smoker to R. J. Israel, principal keeper of Point Loma Light-house, San Diego, Cal. He is a big bee-man. He has dug two swarms out of the hills. Point Loma is nine miles long and five miles wide, and he has made the whole peninsula a howling wilderness—to get these bees. Send him a smoker. ISRAEL & Co.

San Diego, Cal.

THE "MIX" IN GLEANINGS.

I think as long as you print so much of interest about bees and honey as you do, we ought to be satisfied. Honey is good, but we could not very well live on it; and in this place we can not make a living by producing it. If I never own another bee, I shall take GLEANINGS for the other matter in it, aside from bees and honey. The Home talks are worth the price to me. So as long as I can get the means, I shall take GLEANINGS.

Mitchell, Mich., June 8, 1885. Mrs. F. L. CHURCH.

A KIND WORD WITH A MORAL TO IT.

I received the duplicate package of bees on the 13th inst., all in fine condition. They are now doing their level best, cleaning house and carrying in pollen. I wish you could know with what satisfaction I received them—not for the value of the bees, but for the pleasure it gives me to have another name to add to my list of business men who think more of their word than of their pocket; for I believe if Providence has any special favors to bestow it will be for the man who regards his word. Thanks, friend Root. W. H. PELTON.

Lanesboro, Pa., June 15, 1885.

THE WAY PROMPTNESS IN BUSINESS WINS CUSTOMERS AND KIND WORDS.

The goods ordered by wire came all right in three days to my home, seven miles from the depot. I really did not know of living in such a fast age. I am deeply in love with you and all your clerks, the packers and shippers included, for your perfect business way of doing things. I want your corresponding clerk to know I highly esteem her punctual, carefully written, and Christianly directed letters. I do not wonder at your success. It's perfectly natural. J. L. CALDWELL.

Mart, Tex.

GLEANINGS AS AN ADVERTISING MEDIUM.

We did a little advertising with you one year ago, and have had a large order this spring.

Fabius, N. Y., June 1, 1885. KNAPP BROS.

In consequence of advertising in GLEANINGS, we are receiving "many more" orders for queens than we expected, and, in fact, more than we had queens to fill them with; but will be in good shape in 3 or 4 days. Will you be good enough to suggest to readers of GLEANINGS to be sure to write their name and address very plain when ordering goods? Almost every one writes the main body of their letter plain enough; but when they come to their name and address they simply make "crow-tracks." We have received one order already that we can not tell where it came from.

Clarksville, N. Y., June 8, 1885. SNYDER & THIPP.

GLEANINGS is a good advertising medium. Our advertisement in it has brought us a large trade. We haven't written you a word yet about the hive machinery we got from you. It works like a charm. RIP-SAWS VS. CUT-OFF SAWS FOR MAKING DIAGONAL CUTS.

Here let us mention one thing. In your A B C book you say, on page 117, to cut out the miter across the end, have your cut-off saw keen and sharp. We wish you would sharpen an 8-inch rip-saw and try it, instead of the cut-off. We saw out that strip all the time with a rip-saw. You may think, because it is across the grain, that a rip-saw won't cut; but it will; we make it a success, and can cut 100 with a rip-saw while we would cut 50 with a cut-off. DIXON & DILLON.

Parrish, Ill., June 9, 1885.

[Friends D. & D. it depends on the kind of lumber you have, somewhat, as to which of the two saws should be used. For nicely seasoned clear lumber, a rip-saw keen and sharp works just about as you mention. Thanks for the kind words.]

"HIS LOVE CONSTRAINETH US."

Was it not a little unkind in you to so hurriedly intimate that I had not acted honestly with you? I love Christ, and his "love constraineth us." Christians will nearly always do as they agree to, at least as nearly as they can. I have had the money saved on purpose for you ever since I said "make out your bill and I will remit." But it is all right, Bro. Root; I am a stranger to you, and I have no doubt you sometimes get deceived as to your man.

Valley Spring, Tex.

O. P. STARK.

[May God bless you for your kind way of putting it, friend S. Please forgive me, if I was a little hasty. The way it came about is, that our book-keepers have instructions to note carefully whatever promise is made when a man is trusted; and whenever a man fails to keep that promise, they are instructed to notify him promptly. You see, we have to work here by general rules, for the magnitude of our business is now away beyond my constant oversight.]

QUEENS NOW READY.

DARK LEATHER-COLORED.

OR LIGHT ITALIANS.

TESTED, \$2.00; UNTESTED, \$1.00 EACH, OR 6 FOR \$5.00.

Address all orders to

E. PETERMAN, WALDO, WISCONSIN.

13-17db L. HEINE, BELLMORE, QUEENS CO., N. Y.

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they want to dispose of, we will insert notices free of charge, as below. We do this because there is hardly value enough to these queens to pay for buying them up and keeping them in stock; and yet it is oftentimes quite an accommodation to those who can not afford higher-priced ones.

I have about one dozen black queens. Price 20c; 25 hybrids at 40c. Hybrids are Italians mated with black drones. Untested Italians, \$1.00. Safe arrival guaranteed.

G. D. BLACK, Brandon, Buchanan Co., Iowa.

I have about one-half dozen hybrid queens (good ones) to sell at 40 cts. each by mail.

O. H. TOWNSEND, Alamo, Kal. Co., Mich.

QUEENS FOR SALE.—8 black queens at 30 cts., and 5 hybrids at 60 cts. All queens under 2 years old. Ready to mail at any time. Safe arrival guaranteed. Make money orders payable at Greensburg, Ind. H. F. SHANNON, Spring Hill, Decatur Co., Ind.

Hybrid queens, 25c each, postpaid. Blacks, 15c.
A. B. SURBER, Center Point, Kerr Co., Texas.

I have two choice hybrid queens which I will sell for 50c each.
J. L. HYDE, Pomfret Landing, Windham Co., Ct.

I have 25 hybrid queens to sell. Ninety per cent of the bees from these queens are three-banded. I will take 50c apiece.
C. A. DEARBORN, (P. O. Box 267), Baraboo, Sauk Co., Wis.

Hybrid queens, 25c each, from cells taken from hybrid colonies in swarming.

L. T. HOPKINS, Conway, Franklin Co., Mass.

I have four or five good prolific hybrid queens, which I will sell at 40c each.
R. J. FOX, Natick, Middlesex Co., Mass.

I have 8 hybrid queens, which I will dispose of after July 15. Price 50 cts. Safe arrival guaranteed.
J. H. WEIDMAN, Riverside, Burlington Co., N. J.

I will sell hybrid and black queens, in July and August, at 35 cts. each, or 3 for one dollar.
W. A. SANDERS, Oak Bowler, Hart Co., Ga.

Five Italian queens, mated, hybrids so called; will sell them for 50 cents each.
J. A. GUNN & CO., Casky, Christian Co., Ky.

I have 13 hybrid queens and 6 black; will take 50 and 25c each.
J. J. HURLBERT, Lyndon, Ill.

I have 4 mated Italian queens that I will sell at 50 cents each, and two hybrids that I will sell at 25 cents each, ready now. Send in your orders to
D. O. WAKEFIELD, Waverly, Lancaster Co., Neb.

Try the Arkansas Brown Germans. I have 13 brown German queens for sale through July, for 50 cts. apiece. Tested queens. Guarantee safe arrival, if anybody wants them.

G. R. HIGHTOWER, Eureka Springs, Ark.

The best Queens out.

I will furnish queens from July 1 to September 1 for one dollar; warranted tested, \$2.00; after then the price will be the same as in A. I. Root's list. Queens all bred from an imported mother.

G. F. SMITH,
13d Bald Mt., Lackawanna Co., Pa.

Foundation-Mills Lower.

Until further notice, prices will be as follows: 4-inch mill, \$10.00; 6-inch mill, \$13.50; 10-in. mill, \$20.00; 12-inch mill, \$30.00; 14-inch mill, \$40.00.

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they want to dispose of, we will put notices free of charge, as below. We do this because there is hardly value enough to these queens to pay for buying them up and keeping them in stock, and yet it is often times quite an accommodation to those who can not afford higher-priced ones.

I have about forty black queens to sell at 25 cents each; and a few misnamed Italians at 50 cts.

A. H. HAMM, Kingston, Caldwell Co., Mo.

We have a lot of choice fine hybrid queens at 60c, and a few pounds of bees to go with them, if wanted, at \$1.00 per lb. Cash with order.

J. C. & D. H. TWEDDY, Smithfield, Jeff. Co., O.

Send for queens, blacks, 25c; hybrids, 35c; and untested Italians, 75c each.

G. W. ALBRECHT, Dundas, Calumet Co., Wis.

Three hybrid queens for sale at forty cents each.

M. ISBELL, Norwich, Chenango Co., N. Y.

I have a few hybrid queens at 50 cts. each. Those rather dark, 40c.

J. S. HOFFMAN,

263 Hepburn St., Williamsport, Pa.

I have about 20 black and a few first-class hybrid queens that I will sell at 25c for blacks and 50c for hybrids, and guarantee safe arrival.

J. RAYMOND BALL, Knowlton, Quebec, Can.

I still have a number of choice hybrid queens that I will take 40 cts. each for, safe arrival guaranteed. Some of them are raised from pure mothers, but misnamed.

G. S. FOX, Mitchellville, Iowa.

I have 30 hybrid queens that I wish to dispose of. Price 40c each by mail.

J. G. COBB, Mt. Cobb, Lack'a Co., Pa.

One black queen for 2 Peet cages and one 2-cent stamp each, or 10 queens for 20 cages and ten 2-cent stamps.

A. L. LIGHT, Pastoria, Ark.

I have some 12 or 15 hybrid queens to dispose of between this and Sept. 1, which I will send postpaid for 35c each; also 2 blacks at 20 cents.

RUSSEL KILBOURNE, Jr., Clinton, Oneida Co., N. Y.

A few tested queens, whose progeny show 2-bands, for 75 cts. each. Also a few dark Italians for 50 cts. each, from pure mothers.

THOMAS HOKIN, Box 691, Sherburne, N. Y.

Bees and Queens

AT REDUCED PRICES.

I will sell two-frame nuclei, full of bees, brood, and honey, with warranted Italian queen, for \$3.00; also untested Italian queens for \$1.00. Give me a trial order, and you will get the worth of your money.

HONEY COLUMN.

CITY MARKETS.

ST. LOUIS.—*Honey*.—Our market continues very dull. In fact, no demand for any kind of honey. Some new in bbls. and cans received this week. Southern extracted, nominal. In bbls., 40c; kegs and cans, Northern, 70¢ to 1.00, by single package. Comb Honey.—One shipment of new received. No demand, weather being so very warm; old, 80¢ to 1.20, nominal. New, held at 15c. *Beeswax*.—Very dull. About 25c, the very best price obtainable—stock large.

W. T. ANDERSON & Co.,

July 9, 1885.

101 N. Third St., St. Louis, Mo.

KANSAS CITY.—*Honey*.—Small lots of new honey are beginning to arrive. Prices about the same as last report. Choice 1-lb. sections, 15¢ to 16¢; 1-lb., 13¢ to 14¢; 2-lb., 10¢ to 12¢. Fancy new comb brings a slight advance on these figures. Extracted, new Southern, 5½¢ to 6¢. Cal., 7c. New white clover, 8c.

Beeswax.—Weak at 25¢ to 30c. We are now making a specialty of beeswax, and will pay highest market price for all we can get, and will furnish beesmen crude or refined wax at a slight advance on cost.

July 2, 1885.

CLEMONS, CLOON & Co.,

Cor. Fourth & Walnut Sts., Kansas City, Mo.

CHICAGO.—*Honey*.—There is very little doing in honey in this market. Not much offered, and fruit of all kinds is cheap, which perhaps retards the sale of honey. Comb, 12¢ to 15¢ for best. Extracted, 5¢ to 7¢.

Beeswax, 20¢ to 22¢.

July 11, 1885.

R. A. BURNETT,

161 So. Water St., Chicago, Ill.

DETROIT.—*Honey*.—The honey market is still dull, though not stagnant. Price is quoted at 10¢ to 12 cts.

July 11, 1885.

A. B. WEED,

Detroit, Mich.

FOR SALE.—2000 lbs. of extracted honey, white clover and lime. Honey is ripe, and of the best quality.

J. B. MURRAY, Ada, Hardin Co., O.

KIND WORDS FROM OUR CUSTOMERS.

Goods came all O. K. I don't wonder that you are overrun with work. Yours was one of the nicest lot of goods I ever received.

S. S. LAWING,

Henderson, Mo., May 14, 1885.

I regret very much that I ever let my subscription run out. I think Mr. Doolittle's article in May No. is worth the price of the book for three years.

La Grange, O.

C. D. MANVILLE.

A FRAME OF BROOD, A POUND OF BEES, AND AN UNTESTED QUEEN, AND HOW THEY PLEASED.

I suppose you are anxious to learn how the bees are getting along which you shipped to me July 7. Well, the little fellows came all right, Wed., the 8th, at night. We got them Thursday morning, and had them in one of your hives by ten o'clock. They had a good fly, and went right to work. Yesterday they looked as though they were swarming, there were so many young bees flying. I feel as if I must thank you for your promptness, and for the nice way in which you sent them. Last fall I had eleven swarms, and I lost every one. I should have sent to you before July for them, but I was so discouraged. I at last obtained one swarm, from which I have another; and with one from you now makes me three. I shall now use your hives, and next fall put them into the chaff hives, and I hope to succeed better with them. I feel I can not give them up entirely yet, for I do love them so, and I love to watch them and study them; and I hope, with God's help, to realize something from them yet.

JULIA M. FREEMAN.

Perry, N. Y., July 12, 1885.

UNTESTED ITALIAN QUEENS,

Raised from imported and best home-bred queens, 90c each; six for \$5.00. Tested, \$1.50 each. Three L. frame nucleus and queen, \$3.00.

● CELLARS VS. CHAFF PACKING.

CELLAR WINTERING, CHAFF PACKING, ETC.

LIVING about six miles from here is an old man who has no bee-book, and reads no bee-paper, but who has for the past eight years successfully wintered his bees in an apartment of his cellar. He buys his hives of bee-keepers who have given up the business in disgust, never paying more than twenty-five cents apiece for them. He has never raised very much honey for sale, very seldom opens a hive, but sells bees in the spring to bee-keepers who are good hands at raising honey, but poor ones at wintering their bees. We visited him a few weeks ago, stayed to dinner, had a good long chat, and bought five colonies of bees. In one corner of his cellar is a room about ten feet square. The floor is cement, the walls and ceiling are plastered. It has two outside windows, which are closed and protected in the winter. Upon the approach of cold weather he carries his bees into the cellar, and simply stacks the hives up as we would so many boxes. He takes them out again "when the snow is gone." He has never lost a colony, except some late swarms that starved. He has tried once or twice leaving one or two colonies out of doors, but has lost them every time. We noticed that the fronts of some of the hives were considerably soiled, and asked if they were in that condition when he bought them.

"Oh, no!" said he; "almost all of them get that way in the winter. They look pretty bad when we bring them out, but the rain soon washes it off. Whenever we go into the room in the winter we find bees out running around upon the front of the hives; they empty themselves, and go back into the hives."

We asked him how warm he kept the room, but he "didn't know." He knew it never froze in the cellar. Whenever we find a hive daubed up like this in the cellar, we mentally write "dead" upon its side. We have known of this man's success for some time, and have attributed it to locality. To test it we have often thought of taking a load of bees over there the latter part of the summer, and getting him to put them into the cellar upon the approach of winter. Last fall a son-in-law of his brought eight colonies there—brought them after cold weather had set in, and put them into the cellar without even giving them a flight, and last spring came and carted them home again, alive and all O. K. All this was rather "upsetting;" but there was no dodging it, *because they had the bees to show*. So much for cellar wintering. Now let us talk of

CHAFF PACKING.

"There is no great loss without some small gain;" if we lose our bees every winter we have the pleasure in the spring of a trip to the home and apiary of Cyula Linswik and her sister. Last spring was no exception, as we again brought home in triumph thirty-one of their best colonies. Although their bees are what would be called light Italians, we have no hesitation in saying that, taking every thing into consideration, they are as good Italians as we have ever had. They are very peaceable, but also very energetic workers. In accordance with our request, one colony had been left packed so that we could see "just how it was done." The hive stood upon a board platform, about three feet square, said platform being raised three or four inches from the ground. A box nearly as large as this platform, but without top or bottom, was set down over the hive, the top reaching four or five

inches above the top of the hive when its cap is removed. A bridge, or tube, about four inches square, led in from the front of the box to the entrance of the hive. When preparing the bees for winter, one comb is removed and the remaining combs spread apart. Little sticks laid across the tops of the frames allow the bees to pass from comb to comb. Over these sticks is laid a woolen cloth, and in the surplus apartments at the sides of the brood-nest are placed chaff cushions.

The large box is filled with chaff, and a cover put on, in the center of which there is a hole a trifle larger than the top of the hive. The ordinary cap to the hive is removed, and another cap substituted that just fills the hole left in the cover to the large box, and sets down over or outside the upper edge of the hive. This cap is filled with chaff, the chaff being kept in place by a cloth tacked to the lower edge of the cap. In the top of the cap is cut a hole nearly a foot square, which is covered with wire cloth to keep out mice. This opening allows the moisture to escape, which is considered of much importance. In one or two instances this upward ventilation was omitted when the entrances became closed with ice. Over the whole is placed a roof of rough boards. The packing is done *early*, so that there need be no disturbance after cool weather sets in. When it is time for snows to come, a board is leaned up in front of the entrance, to keep out the snow. The little bridge leading to the entrance is not allowed to become filled with snow. If any snow blows in it is *very carefully* brushed out with a wing. The packing is allowed to remain until all danger of even cool weather is past. It was May 18th when we were there, and the unpacking had been finished the previous day. We were never more favorably impressed with the importance of *spring* packing. In the colony that was packed great masses of bees were hanging out in the surplus apartments at the sides of the brood-nest; while other colonies that were unpacked, that were, we were informed, no stronger, showed little if any disposition to hang out. The hand thrust down into the chaff outside of the hive showed it to be *quite* warm. Even though inclined to adopt cellar wintering, we think it will be found profitable to pack the bees in the spring, after taking them from the cellar. The fine, strong, booming colonies found at "Our Clearing" have stimulated our ambition wonderfully to winter our bees in a like successful manner, and, feeling that "what man hath done man can do," we shall put forth extra exertions to winter our bees another winter. Now don't joke us, friend Root, and say it was a *woman* who has so successfully wintered her bees. If you do, we shall tell you that Dr. Southard, of Kalamazoo, Mich., wintered his entire apiary of 100 colonies, and they were packed out of doors. Cyula and her sister jokingly offered to winter some of our bees if we would send them up there, and we are more than half inclined to send half a dozen colonies, just for the fun of the thing, and to see how it will turn out. It is, perhaps, but fair to say that two or three colonies in the "Linswik Apiary" did not winter so perfectly as the others, and were considerably weaker, and that the proprietors could not tell the reason why.

A FEW WORDS IN DEFENSE OF G. W. GATES.

Mr. Gates may not feel like defending himself, so please allow me to say that I know one of his little boys was very sick, and that Mrs. G., who usually

helped Mr. G. in packing bees for shipment, had to stay in the house and care for the sick child. Then Mr. Gates' man caught his hand in a horse power, and he was left short of help. Bees were swarming, every thing full of honey, and no time to extract; queens hatching, and tearing down cells because they could not be attended to. Then another child was taken sick, and friend G. certainly had his hands full. All this time orders were fairly *pouring* in. Had Mrs. Chaddock known all this, probably she would have been more charitable. It was of friend Gates that I bought the bees by the pound, as mentioned in the July GLEANINGS, and I have found him the very soul of honor.

S.—W. Z. HUTCHINSON, 75—100.

Rogersville, Mich., July 8, 1885.

SPIDERS AND BEES.

Spiders are one of the Bee-Keepers' best friends to preserve empty Combs from the Ravages of the Bee-Moth.

BY REV. L. L. LANGSTROTH.

NEVER, since the introduction of movable frames, has there been in our country a greater mortality among bees than during the last winter and spring. Before the use of these frames, to most bee-keepers such losses were irreparable. How often, by natural swarming, did the old-fashioned bee-keeper, when a few good seasons came in succession, make such a success in the business as convinced him that a given sum of money invested in bees paid better than any thing else? But sooner or later comes the bad year—when most and perhaps all of his colonies are lost—his golden dreams vanish, and in most cases he abandons the pursuit in disgust, having nothing to show for his investment but some empty hives (extra nice for kindling-wood), and some combs, of value only for their wax. Was he one of the kind who have little use in their vocabulary for the word failure? Being able to make but little if any use of his old combs, he painfully waited upon the seasons; and unless he had in him the making of another Quinby or Grimm, he could hope to build up his apiary again only if favored by a succession of favored seasons.

We have had some very calamitous seasons since movable frames began to be extensively used; but by those who know their business, how quickly are such losses repaired! Although not very often referred to, this power of speedy recuperation is one of the greatest benefits which come from the control of the combs. Nearly every empty comb can be utilized for the bees, especially since the era of sending queens by mail and purchasing bees by the pound; and even if he has lost all his colonies, no one need call himself a bankrupt bee-keeper, but in a single favorable season may hear again the cheerful hum of industry in hives no longer desolate and silent. The change so speedily effected seems almost like a resurrection of the dead!

But it takes *time*, even with the best management, to secure such results, and just here comes a new element which *must* be taken into account. Nothing is so acceptable to the bee-moth as combs with no bees to protect them; the older the combs, and the better in all respects for the bees, the better, too, for the moth; and the great question is, how with the least trouble can these empty combs be

saved? Hang them up in some light and dry place, carefully separated so that they nowhere touch each other, and sulphur them from time to time. Most of you know by heart this old, old story, and many of you only to neglect what requires so much care, and time never waits upon any procrastinator. You need not be told that eternal vigilance is the price which *must* be paid if we would save empty combs for the bees.

Columella said, nearly two thousand years ago: "This business [bee-keeping] demands *maximam fidelitatem* [the greatest fidelity], which, since it is the rarest of qualities," etc. It is just as hard to find it now as then, but we never needed it more, and I proceed to tell those who are conscious that they are weak in this matter, how "without money and without price" they may secure it. The facts which I shall now give are recorded in my private journal, and have been often told to bee keepers, some of whom will, no doubt, remember them as given by me many years ago. Within a year or two my methods have been given in part to bee-keepers by some German apiarist—and how much do we owe to our German friends, among whom Dzierzon stands first!

I extract now, word for word, from my Journal, Vol. I., under date of July 8, 1864:

"*Spiders* I count as friends. Last season I put away small frames of comb under a box, and the spiders kept them free from moths: this year I had a number of hives with combs, but no bees, and they have guarded them *well*! Where a spider has her web, there it will be safe to keep empty combs."

I will now explain more fully how I came to find the spider's value to the bee-keeper. A nucleus with a choice imported Italian queen was placed on an empty box hive laid on its side upon the ground, with its cavity facing the north, to protect its contents from the sun. In this cavity I put quite a number of frames with choice combs to be given from time to time to the nucleus, when frames of brood for queen-rearing were taken from it. I expected that some, at least, of these combs would be visited by the bee-moth; but examining each comb as I took it from the old box, I found no signs that they had hurt them. This surprised me much, until I saw, when I came to the further end of the box, a *spider's web* with its occupant, and many proofs of the kind of work that had been done (all unknown to me) in the shape of skeletons of bee-moth and other insects suspended in that web.

It was not until next year that I reaped any great benefit from seeing the handiwork of this spider. Dec. 30, 1863, the weather at Oxford, Ohio, was quite mild for a winter day, the mercury ranging at about 42°, the day being misty and threatening rain. At 5:30 p. m. my thermometer was 42°. The wind began to rise, and at 6:30 p. m., the record was 32°; 7:30 p. m., 22°; 10:30 p. m., 8°. Jan. 1, 1864, 7 a. m., 16° below zero, with a gale of wind. What soldier who camped out that day will ever forget it? In our apiary were many weak colonies, wintered only because we could then sell every tested queen we could spare in the spring for from \$10 to \$20. Nearly every one of these weak colonies was dead when I examined them after nearly two weeks of unusually cold weather. The hives with their empty combs were piled up against the north side of the barn, and shut up only enough to exclude mice. It was quite late in the spring before my health allowed me to give them any attention, and my son was absent in the army. But I was able to use

every comb in my various operations. The spiders had taken possession of them, and the bee-moth had no chance. Had I closed the hives so tightly that the moth could not have got in them, I should in all probability have lost most of the empty combs. The odor of such hives attracts the moth; and if she can not enter them she will lay her eggs in the most convenient cracks and crevices for her progeny to get access to their proper food. It is much easier for a spider to entrap the moth than it is for her to catch her larvæ when once they have burrowed into the combs. I prefer, therefore, to give the moth the freest possible admission, consistent with excluding mice, to all hives with empty combs.

Solomon says: "The spider taketh hold with her hands, and is in kings' palaces." And she is very fond of making her hunting grounds in the combs of our queens' palaces when no longer under the protection of the bees! But we need trust nothing, even to her alacrity, to *volunteer* in our service. In our barns and woodsheds can always be found in autumn and early spring a supply of those white bags in which the provident mother so nicely tucks up, as in the softest silken cradles, her eggs to be developed in due time by the increasing warmth of the season. Put a single one of these so-called "spider bags" into each hive with empty combs, and be no more anxious about them—you have got "without money and without price" that vigilant fidelity so indispensable in this matter. The spider is now your very good friend. She mounts guard over your combs, and will protect them from the moth until the last one has found its proper place with your bees.

I regret that this information was not given long ago to the bee-keeping world. It was intended to appear years ago in the revision which I hoped to make of my work on the "Hive and Honey-Bee." I specially regret that I could not give it last spring when it would have been of so much greater service. But it is only within a very short time that I have recovered sufficiently from my old head trouble to take any interest in bees, or to write on any thing connected with them. With gratitude to our heavenly Father, "who forgiveth all our iniquities and healeth all our diseases," and with hearty good will to all bee-keepers at home and abroad, I sign myself their friend.

Oxford, Ohio, July 1, 1885. L. L. LANGSTROTH.

N. B.—July 7, 1885. I have just taken from a loft over my woodshed some old combs of the kind that the moth loves, and that have lain there in an open nucleus box since 1874! They have not been molested, and the spider-webs adhering to them tell in short the whole of this long story. L. L. L.

Friend L., the suggestion you make is new to me. I have often seen combs covered with spider-webs, but it did not occur to me, until I had read the above, that such combs are usually found free from the moth. In fact, after thinking the matter over I remember to have seen many times the combs entirely free from moth, but I never knew just how it was before. Now, this is quite an item, and I don't know but quite an invention, if any thing can be called an invention that was not invented, or that invented itself. But for all that, I have been so much accustomed to regarding spider-webs as an indication of slovenly habits, that I feel al-

most as though I would as soon have my combs destroyed by moth as to be covered with spider-webs. This would not be a very rational conclusion, however, after all, for a brush-broom would remove the spider-webs in a moment, and ungainly holes in the combs by moths can not well be remedied. Is it true, that any sort of spider is a protection in this way, and that these spiders' cocoons we find would, any of them, do the business? Very likely it is; but the matter is all entirely new to me, and doubtless we shall be able to take advantage of it.—I have often thought of it, friend L., even if I have not talked much about it, and it is wonderful how bee-keepers build up after disastrous losses; for, in fact, if a bee-keeper has every thing else in good trim, even if his bees are all dead he is not so very badly off. For a small amount, comparatively, expended in buying bees in the fore part of the season may put him almost where he was, before the close of basswood bloom.

THE MANGROVE HONEY OF FLORIDA.

ALSO SOMETHING ABOUT THE "STAYING" QUALITIES OF THE CELEBRATED CALIFORNIA HONEY, COMPARED WITH WHITE CLOVER, ETC.

IN my late article on Florida, page 450, in the last line on the page is an omission, either of my own or of the type-setter. The sentence should read, "The Florida yellow pine makes excellent lumber for hives, but is quite heavy, and for that reason, etc."

You ask about the staying qualities of mangrove honey, as compared with California sage honey. While the color, body, and peculiar aromatic flavor of the sage honey is undoubtedly very fine, a single glance at the market reports will show that it lacks much of standing as high in general estimation as it did when first introduced. For the past few months, at least, California honey has invariably been quoted in our leading markets at from one to four cents less per pound than white-clover honey. Our good friend Mr. Muth told me, some four or five years ago, that he at one time made a determined, persistent effort to introduce California honey to his trade, but utterly failed, his customers preferring clover honey, even at a higher price. He has also handled the Florida honey more largely than any other dealer, during the past three or four years; and if you could secure a statement from him as to its quality, you would very much oblige myself as well as others who are interested in this matter.

This honey has been on our markets only a short time, and in very limited quantities at that; and the fact is, that none of us, unless it may be Mr. Muth, knows any thing about its staying qualities compared with our Northern honey.

I think the rule is, that none of our higher-flavored kinds of honey, such as basswood, California sage, etc., is as generally liked as is the more mild-flavored kinds. If I am correct in this opinion, then mangrove honey will probably prove valuable for its staying qualities, as it is of an exceptionally mild flavor, as stated in my first article. For my own eating, I prefer it to white-clover honey; but the likes or dislikes of one person prove little.

We have a little home down there at Hawk's

Park; and when we get to living there, as we hope to some time, just step in some morning and test our honey for yourself; and perhaps, if we happen to be a little extra generous at the time, we may allow you to sample an orange or two also.

O. O. POPPLETON.

Williamstown, Iowa, July 10, 1885.

MRS. CHADDOCK TALKS TO US ABOUT MARKET GARDENING AND BEES.

SHE ALSO HAS SOMETHING TO SAY IN REGARD TO PROMPTNESS AND ACCURACY IN BUSINESS.

EVERY time that you print an article of mine, and then put one of those inimitable foot-notes after it, I feel as if I wanted to "answer back."

I do not have the least doubt but that Mr. Gates is a good man. I was not anxious to get the money back; but I was suffering for some bees—or, rather, the combs were getting moths in them, and I was nervously anxious to put some bees on them, and I wanted him to send me some "right away;" and if he could not do it, then I wanted him to say so *instantly*, so that I could send somewhere else. I beg Mr. Gates' pardon if I have done him an injury. In fact, I supposed that if Mr. Gates was all right you would put my communication in the waste-basket.

You say that you suppose I have built up a large business in the market-gardening trade. I have not. In fact, I do not do any thing in the business, worth mentioning. Why? When I began raising vegetables for market we had just bought this farm, and had gone in debt for it. We paid \$8000 for it, and all but thirteen hundred dollars was borrowed money. We had no way of making money but by farming. I was young and ambitious, and I thought I could help along by raising things to sell. Mr. Chaddock was never willing for me to do it. He was willing for me to bind rye all day, or husk corn day after day for weeks, but he thought peddling produce was "small business." He said we lived too far from market (and we do), and that he could not spare the horses in the working season. His arguments were all good, and I felt the weight of them; but we were so scarce of clothes and dishes, and every thing, that I begged him to let me try it. At that time the Rockford & Rock Island Railroad was being built through Vermont, and the influx of the railroad hands made a good time for the taverns and boarding-houses, and that meant a good time for the produce-raiser. After the railroad was built, and the hands left, there was not so good a market; and as we had reduced our indebtedness from near seven thousand to three thousand, and were paying seven per cent interest, instead of ten, I got inflated, and felt above the peddling business. About that time I began keeping bees, and writing for pay, and I thought I had too much to do. Last year I was sick; I never touched a hoe the season through, and we never had a whole mess of lima beans, nor a single green bean to eat, the whole season.

When Mrs. L. Harrison visited us in August, she was very much worried because there was nothing to sell. We took her to Vermont to the train; and before we left her we bought a watermelon. After she went home she wrote me, "I can not help thinking of that buggy going to town with nothing under the seat to buy the 'gude mon' a watermelon." I

answered her, that if I were able I would go right to cutting cordwood, so as to be sure to have something to sell the next time she came to see me. I expect her to visit me again this fall, and all this spring I have been planning to give her pleasure. I have planted a lot of squashes; and when we go out riding next time, I intend to take out the buggy seats and pile the bed full of big squashes; and when we go to get in I will invite her to a seat on a mammoth squash, and, seating myself on another, we will ride gaily along. Mrs. H.'s head is level, and so is her heart, and I like to joke with her.

Now as you do not seem to like compliments very well, I will give you a taste of the wormwood; and I say at the start, that I don't want any more bees in the place of them, or to make it right; for it is all right now; that is, all but the *remainder* of it. I *reconsider* why the half-pound packages of bees that I got of you do not build up like those that Bro. Phillips got of Dixon & Dillon, of Parish, Ill. I got mine first, and I put a comb full of brood (in all stages) in each of mine. One of them now has two full frames, and a little in two more; the other has three full ones, and two partly filled, while Bro. Phillips' are rushing and roaring, and in need of the section boxes. He put his on empty combs where the bees died, and they ate sour honey, too, but he did not give them any brood; they had to do it all. It can not be in the management, for I helped him, and I did just as I did with my own, with the exception of the brood given to mine.

MORE SLOWNESS.

When my combs were standing empty so long, I went to a neighbor's, and told them I wanted to buy a swarm of bees, and would give two dollars for one, put into my hive. There was no one at home but a young woman of sixteen. She promised to ask her father if I could have them, and send word to school by her sister, who would tell Jessie, and she would tell me. Every day for ten days I asked for news of those bees. Then I borrowed two dollars and sent for two pounds of German brown bees, and the very next day this neighbor's family "roused itself," and the mother came over to tell me that I could have as many swarms as I wanted, and they would take strawberries for pay. There it was; they had more bees than they wanted, and I had more strawberries than I wanted, but the girl "forgot to tell her pa" until I had sent my two dollars away, and then they had to pay the money for the berries. Now, I do not believe that one of my children would "forget" to tell me, if any one wanted to buy any thing of me; even little Harry has more business principle than that.

Vermont, Ill.

MAHALA B. CHADDOCK.

Mrs. C., I am very glad of the turn your letter has taken, because it helps to solve this great problem of what to do—a problem that is so intensely interesting to those who have farms with mortgages on them, just as you and your good man had when you started. And now when bee-keeping seems a little dull, and the price of honey low, many bee-keepers are wanting to know what else they can do. They all have ground, more or less of it; and if they have learned to sell and produce honey, they will very quickly learn how to produce garden stuff. I did not really suppose that you had built up a big business, but I knew you would have done so, if you had kept on. In trying to

find something for our boys and girls to do here, we have done a little something at this kind of work; but it is not much use to try, unless you can find boys and girls who love plants, and who love to work with them. On a single bit of earth, covered by a glass sash 3 by 6 feet, we have this season produced vegetables that would have sold for a couple of dollars or more, had we been inclined to sell them; and on a piece of ground, perhaps not more than 15 feet square, we have, without the aid of any sash, raised and sold over ten dollars' worth of cabbage-plants. The only expense put on the ground was perhaps 50 cents' worth of stable manure, and may be one day's work, all together. Our cabbage-plants, celery-plants, and plants of every kind, in fact, have all been sold at good prices, and we could have sold a good many more.—In regard to the wormwood, by all means give it to us when we need it, and it will likely do us good; but I do not quite get at the point, why our half-pound packages of bees do not build up like those you got from Dixon & Dillon. Do they give bigger half-pounds? or are their bees younger and smarter? or did it just happen so? I have observed this, that some half-pounds of bees with a queen will often go away ahead of some other half-pounds with a queen; but I have never seen a case where I had not good reason to believe a frame of brood was a very great help.—Your experience with little girls is just about what I should have expected of the average little girl. And it is not the little girls only; but that little girls and little boys, both of them, grow up big and stay just that way. It does vex me beyond any thing I can think of, to intrust some important commission to some persons, and when they discover they have caused much trouble and much loss of property by their forgetfulness, to have them say nothing, and go on without even thinking to make any sort of an apology. When anybody has wronged me by accident or heedlessness, if he will show his regret by a real genuine apology, and offer to take out his pocket-book and make good the damage, why, of course, I always feel like letting it pass, and calling it square. But I do like to see people wake up once in a while, and show that they have some regard or care for what is going on in this world of ours.—So you still raise strawberries, Mrs. C., even if you have let the garden "sass" go.

THE OHIO STATE BEE-KEEPERS' ASSOCIATION.

SOMETHING IN REGARD TO THE MATTER.

I WANT to make an apology to our Ohio brethren; but before doing so I will give place to the following kind letter:

Friend Root:

You will see that you are not forgotten, even if you were not present at our convention, as they have elected you president of the Ohio State Bee-Keepers' Association. They suspended the rules, and elected you by acclamation unanimously, which I hope you will accept as cheerfully as it was tendered you. J. T. Martin, of Tiffin, was

elected vice-president, and your humble servant treasurer and secretary. C. M. KINGSBURY.

Mt. Vernon, Ohio, Feb. 18, 1885.

You will notice, that in the above letter no mention is made of the time when this association meets again, and I have been "waiting and watching" ever since I got back from New Orleans, for something in regard to the matter. As the convention usually meets at the time of the Ohio State Fair, I presume there will be such a meeting this year; but I am ashamed to confess, that at present I have not been able to find out when or where I am expected to officiate as president; however, I will take immediate steps to find out, and will try to be on hand, and do all in my power to make the convention a success. It has sometimes been quite hard for me to do much mental work unless I do it an hour or so at a time, with a good many recesses thrown in. On this account I have to depend a good deal upon our good friend Martin, vice-president, and friend Kingsbury, who writes the above kind letter. Ernest will go with me as private secretary, and perhaps he can help some.

RECENT DEVELOPMENTS,

And Suggestions and Queries Particularly Pertaining to the Season.

CARNIOLAN BEES.

WILL you please tell us in the next issue of GLEANINGS what your experience has been with the Carniolan bees, and does it agree with friend Benton's? Ask those that have tried them to report. We are greatly interested in them, and wish to know more.

Mt. Vernon, Ill.

W. W. ADDISON.

Friend A., we have never yet seen a Carniolan bee. We told Benton nearly a year ago to send us a couple at once. He wrote that it was too late in the season, but that they would come early this spring. They have not yet come, and he has not as yet given any explanation, yet we notice he has been sending them to others. I wonder if he is afraid to have them subjected to the test and scrutiny they will likely meet with at the "Home of the Honey-Bees."

A REPORT FROM THE ALLEY DRONE-EXCLUDER.

In using the Alley drone-excluder I find that the drones thus excluded sometimes go to other hives. In using the drone-trap, several young queens going out for mating could not or would not pass through the zinc, but passed up the cone and there remained until liberated by drawing the slide. On returning they could not get in till the trap was removed.

D. F. SAVAGE.

Casky, Ky., June 30, 1885.

MRS. COTTON.

Friend Root:—For years it has been apparent that Mrs. Cotton, of West Gorham, Maine, has been imposing upon the public, and the matter has been referred to the Maine Association, and we wish to obtain what information we can in regard to the matter. Will you please give me what information you have in your possession? Do not refer me to GLEANINGS, for I have cut out and sent to publish-

ers of papers, in order to stop her frauds, all or nearly all that has appeared, and so I have not the complaints on hand now. Should you think it just and right to do so, I would ask that you request, through GLEANINGS, that all who have for the last ten years been defrauded by Mrs. Cotton send a plain short statement of it to JAMES B. MASON, Mechanic Falls, Maine, President of Maine Bee-Keepers' Association.

DRY FECES.

I notice in GLEANINGS for June 1st that Professor Cook would confine the controversy on dry feces to the droppings found on the bottom-board. The defenders of that theory do not purpose being so limited. Dry feces we understand to be such as have so small a percentage of moisture as to retain their form, no matter when or where voided. While some such may be found in the debris underneath the cluster, the far greater part will be voided after the bees are set out. We are glad to learn, through the *Canadian Bee-Journal*, that S. Corneil, who has no superior in America as a scientific writer on apiculture, has commenced the investigation of this subject. When he gets through we shall have something that all can depend upon. P. H. ELWOOD.

Starkville, N. Y., June 24, 1885.

DRONES FROM WORKER EGGS, ONCE MORE.

I wrote you last year that I believed drones could be had any time the queen was laying. I have demonstrated the fact, and several others that I told of it. Take the queen out and I guarantee drones. Sometimes only two or three will be raised. If no drone comb is in or near the brood-nest, they will build out worker-cells, and raise them there. Mr. Hofensteter, of Louisville, deserves more credit for the discovery than myself. He put me on the track of it by saying on a card to me that the queen laid all one kind of eggs. I am confident he was right, but I stick to the theory that the bees feed the queen something besides honey to bring her into laying condition. If she lives on honey only it looks reasonable that her condition would always be the same. M. L. WILLIAMS.

Maysville, Ky.

REPORTS ENCOURAGING.

WE are having a good honey season so far. The yield from apple-blossom was the best I ever knew. The bees filled up the brood-combs so that I had to extract to give the queen room to lay. I took about 100 lbs. of extracted honey from eight or ten stocks, besides a little comb honey, all from apple-blossom.

Naugatuck, Ct., July 2, 1885.

R. DOWNS.

Bees are doing splendidly on alsike clover, and swarming furiously, with basswood about two weeks ahead. Our bees have never been in so fine condition at this season since 1880.

Wyoming, N. Y.

G. W. STANLEY & BRO.

I have 140 colonies of bees; wintered all right; doing pretty well now.

FRANK GENTRY.

Riverton, Miss., June 8, 1885.

My bees are doing nicely. I have 28 in Simplicity hives, 12 in Langstroth hives, and 47 in cross-sticks. I sold 1200 lbs. of comb honey last year.

W. S. FESSENDEN.

Kerrville, Texas, June 12, 1885.

THE BEES AND SHEEP CONTROVERSY.

FRIEND MILLER ALSO HAS HIS SAY IN REGARD TO THE CONTENTS OF GLEANINGS.

A BONA-FIDE suit has been commenced against a Wisconsin bee-keeper, Mr. S. I. Freeborn, by an owner of sheep, on the ground that the visits of the bees to the pasture ground are detrimental to the sheep. If I am not mistaken, there has been some loss of life among the sheep, and they have not been doing well, and for this damage the bee-keeper is expected to pay. It hardly seems possible that any one could be so absurdly unreasonable, in this enlightened age, as to really commence suit on such grounds, for there is no danger of any harm to the sheep from bees, and the bees working on the clover-blossoms will insure a better crop of clover for the future. Furthermore, if a neighbor of mine were sure that bees on his pasture were killing his sheep, how could he prove they were *my* bees? I doubt if I could identify a single bee as my property, if it were working half a mile or even half a rod from the apiary. However we may laugh at the thing as unreasonable, the course of the law is so uncertain that it would not be beyond the range of possibilities for Mr. Freeborn to find the suit go against him, in which case a precedent would be established by which any bee-keeper might find himself subject to blackmail levied upon him by the owner of any flock of sheep within three miles of his apiary. A plan has been started in the *A. B. J.* for a "National Union," for defense in such cases. Either this or some other plan should be adopted, for we are all interested, and I doubt not there will be enough to help bear the expense so that Mr. Freeborn can afford to continue the suit to a rightful issue.

WHAT GLEANINGS SHOULD CONTAIN.

As the subject seems more or less under discussion, I suppose I have the right to say. I can not at all agree with the editor, that by putting the motto on the title-page, "Peace on earth," etc., he thereby acquires the right to fill the pages of GLEANINGS with matter at all different from what it should be without the motto. If my grocer had this motto over his door, and should send me a dollar's worth of prayer-books when I sent for sugar, I should not like it. The motto is a good one, but does not give the right to talk about potatoes and strawberries; and if that right exists it must be on other grounds. The matter looks to me like this: There was something like a contract, that the publisher of GLEANINGS was to furnish me so much reading-matter about bee-keeping. In the course of time some of the space was taken up with religious matter; and although I believe in religion most heartily, I thought this a violation of the contract, and thought I had the right to enter a protest. Then extra pages were added, so that there was no deduction from the space for bee-lore, and, of course, I could make no objection. Gradually other matters were introduced—potatoes, carp, strawberries, etc.; but as the pages were increased in number many times more than enough to occupy the extraneous matter, I received more instead of less bee-literature, consequently I had no right to complain. Bro. Hutchinson, isn't that about the way the matter stands? Don't you get all you bargained for, with the extra matter thrown in? New subscribers certainly can not complain, for they knew be-

forehand what they are to have—a journal filled in the main with bee-matters; the editor, however, reserving the right to switch off upon any topic that he thinks interesting or useful; and if they do not like the dish, they are under no compulsion to buy and pay for it. Of course, we all know better than the editor just how to run matters, and any of us could edit a better paper; but on the whole I should sorely miss the visit of GLEANINGS every other week; and if one little matter can be remedied, I will consent not to ruin Mr. Root's business by ordering my paper stopped. I allude to having matters mixed up so that I must read articles that I do not care for all through, for fear I may miss some information about bees. If I send for five pounds of rice, and my grocer sends me also a quarter of a pound of mustard seed without charging for the latter, I thank him for it; but if he mixes it all up with the rice, the trouble of picking out makes it worth less than if I got the rice alone. If I am very busy, and about to start out to put on supers, and GLEANINGS comes, I want to sit right down and read it through before I put on the supers, in hopes to find a better way. But I don't want to take time just then, however much I might like it when at leisure, to read how a correspondent manages to school children or plant strawberries. Now, Mr. Editor, I am not at all exacting; you needn't change the numbers of GLEANINGS you send to the others at all; but please print separately the one you send me, and label one department, "This is nice reading, but there isn't a word about bees in it." If you will do this, I will continue to pay the high price I have been paying, and not stop my paper.

MATTHEW, 2 III.

C. C. MILLER, 179.

Friend M., you make a good point on the bees and sheep controversy. At the time I had the trouble with the cider-mill man, there was talk of prosecution. "But," said I, "my friend, if you commence the suit against me you will also have to commence one against all other bee-keepers within range;" and I convinced him by showing him bees flying in other directions as well as toward my apiary. At other times, when the bees meddled with the preserving and canning business, and the men talked of recompense for their losses, I suggested that every man who kept bees should pay his proportion of the losses. They, however, urged that, as I kept by far the largest number, I ought to pay the greater part of the damages; and may be our friend Freeborn, of Wisconsin, keeps more bees than anybody else in that vicinity.—In regard to having things mixed up in GLEANINGS, I believe we use more small-capital headings than any other journal published, in order to enable our friends to find out what a paragraph is about before they read it; and if GLEANINGS were divided we should have to divide the articles almost into sentences; and a part of your own communication, friend M., would have to go into one department and part in another. In regard to printing a different one for you, I am *really* afraid you will have to wait until we get ahead with our work a little. Then another thing: Some of your neighbors might see it and then *they* would want one printed "expressly to order" too. We have already got the children fenced off in a place by themselves;

but I am expecting every day as they grow bigger some of them will get out and be found around among the old folks; and then if one of the old folks should get in among the children, what trouble they would make! Never mind; we are going to keep trying.

REVERSIBLE FRAMES.

FRIEND HEDDON'S REPORT AFTER USING THEM A SECOND SEASON.

IN response to your request for reports regarding "reversible frames," I will say that we now have about 350 colonies in two apiaries, with an average of about 14 frames per colony, as most of them have two sets of eight each. Something over half of these 5000 frames are our style of reversible frames, which have been described, and I believe illustrated, in GLEANINGS, within the last year.

I have to report not only practical success in their manipulation (the second year of their use), not only as far as gluing, etc., is concerned, but the generally conceived advantages of reversing are more than realized. The comfort of frames solid full of comb, and that comb nearly solid full of brood, is pleasing to the eye of the apiarist. I find the three-fourths space between the lower half of the end of the frame and the hive a great advantage. A few hives that were overlooked, and became clogged with honey, crowding out the queen, had to have their brood-combs extracted. Before replacing them with the bees we reversed them, giving plenty of surplus room above, and this reversing prevented any further clogging of the brood-frames. I am pleased beyond expectation, and never expect to use else but reversible frames for either comb or extracted honey production. We are practicing

MODERN TRANSFERRING

with over 50 colonies, and it seems like changing the railroad train for the ox-cart, to think of going back to the old method of transferring bees.

OUR METHOD OF PREVENTING AFTER-SWARMS, as given on page 414, is working perfectly in several places in our yard. I do not remember of a single failure in my experience.

Before closing, I wish to say a word in regard to our

HONEY MARKETS.

There will be many locations throughout our United States, where not nearly enough honey will be produced to supply the local demand. Many of those who have become discouraged, and given up, will (now that the wintering problem is under control), soon go to bee-keeping again. It will be a fatal mistake to allow the taste for honey to die out in their locality. They should see to it that the supply is equal to the demand, by purchasing honey at wholesale and retailing it at such prices as will pay them for the trouble, and can be afforded by the consumer. This is more particularly an important matter with extracted honey. It is not only important for the individual, but for the whole fraternity. Keep your market always well supplied.

JAMES HEDDON.

Dowagiac, Mich., July 6, 1885.

I am very glad indeed to hear that you still like reversible frames.—In regard to "modern transferring," I suppose many of the readers, like myself, have forgotten just

what you mean by this term. Will you please briefly describe it again, or refer us to where your former description may be found? If I recollect aright, it is in using frames filled with foundation mainly, in place of the old irregular combs to be found in most box hives.—I would emphasize most strongly your concluding remarks. Every bee-keeper should let it be known that honey can always be had by going to his residence; and let packages of all sizes from half a pound up be always in readiness to pick up and take off at a moment's notice. There is a steady demand for good honey, and the demand is not very likely to decrease, providing the honey can always be found by going after it.

REPORT FROM ARKANSAS.

MAKING A BUZZ-SAW TABLE OUT OF A GIN-STAND.

AS no reports have appeared in GLEANINGS from this portion of the State, here are a few jottings. Bees wintered well. I do not know of a single stock that has died. My bees at fruit-blooming had from 10 to 25 lbs. of honey. I transferred five stocks at the beginning of fruit-bloom, and was compelled to take most of their honey, on account of weight. We had nearly one week of fine weather at this time, and bees did finely; but cool cloudy weather set in, so they could do but little, and lasted until fruit-bloom was gone.

Our next show was blackberries, and I am not quite sure that they got any honey from this; but the weather still stayed cool up to the last three days. I fed all I was able to, and yet my bees that were transferred are still short of stores, as well as my new swarms, of which I have had three more than any one that I know of in this part of the country.

Our next show is persimmon. It will soon be in bloom. It yields more and better honey than any thing in this country. Then comes in horsemint, goldenrod, sumac, all of which yield honey. Then comes in the Spanish needle and partridge pea. I forgot to say, that we have but little white clover, and its blooming is over. I have not seen a bee on a head this spring. Our prospects are indeed gloomy—more so to one like me who has put his all into the business. Bad health induced me to hurry up my inclination to go into the business. I heard from friend W. D. Scott one week ago. He is an enterprising apiarist of this county, but his bees are doing badly for want of forage. We have several men in this county who are extensively engaged in the business; to wit, Scott, Clinton, Blackwell, Thomson, Potillar, Pledges, and others; but with what success, I do not know.

I would say to my Southern friends who contemplate going into hive-making, if you can get a Carver gin-stand, you have a saw-table made. Remove the saws from the shaft, leave the pulley on one end and the band wheel (that runs the brush) on the other; you will find a casting on the shaft inside of saws that you can easily build a band wheel on; bolt your cross-framing to cross-beam of stand for your saws, and you have one of the best saw-tables for horse or steam power in market. You have two band wheels on one shaft—one for cut off, and the other for rip. I advanced my cut

off 2 feet from rip, so I can cut the widest board without touching the rip. I have one in my shop that I have made 30 Simplicity 8-frame hives from this spring, with frames and separators and section boxes, and I would not exchange it for the best table in market.

5—E. SUGG, 10—13.

Box Spring, +o Yell Co., Ark., May 25, 1885.

Friend S., we thank you for your suggestion in regard to extemporizing a buzz-saw table from a gin-stand; but as these things are not familiar to us Northern folks, we shall have to confess that we do not quite understand it, but I presume our Southern readers will know all about it.—Are you sure, friend S., that you fully utilized all the honey that has been gathered in your vicinity?

WINTERING BEES.

How Friend Hurd Wintered His Bees When Others Failed.

ALSO SOME FACTS ON TOP VENTILATION FOR CURING DYSENTERY.

I STARTED two years ago this fall with 35 colonies, all black; lost two in wintering. My excess was 54 last year, making me 87 colonies. I bought 5 Italian queens a year ago of J. S. Harvey, for which I paid him \$11.00. I reared 25 nice queens last year from them, and had the old ones left, making me 30 in all, pure Italian queens. I went into winter quarters with my bees in fine condition, as I thought, and I guess they were. I got through the winter with 50 colonies, all on their winter stands. My hives are made of oak, $\frac{1}{4}$ of an inch thick, and I used no wind-break, no cushion, nor any thing of the kind, and my bees went through the winter better than any others through this country. Nearly all the bees through this section are dead. How is this, that mine went through in these light hives without protection? I will tell you. At one time during the winter I found that my bees had dysentery, and I immediately made top ventilation in my hive so the air could pass through the hive from the bottom to the top and pass out; the bees were all right in a few days. Mr. Edward Young, a bee-man, was here when I was fixing the ventilator, and he said it was a grand idea, and fixed his bees the same way, and he came through all right. Mr. Root, I should like to have your opinion on this ventilation at the top, so the fresh air can pass through the hive, in case of dysentery, to carry the filthy smell away. Don't you think it a good thing? It saved my bees this winter, I am satisfied.

ROUSSEAU HURD.

Mt. Erie, Ill., June 18, 1885.

Friend H., it is a fact, as a great many reports scattered through our journals for years past will show, that abundant ventilation through a hive will save them where other stocks not so ventilated die. Hives split open, tipped over, or left by accident so the wind whistles right through them, will winter during a disastrous season, when all the others die. This has been proven over and over again; and our directions for wintering, as given in the A B C book, are all based on this point; viz., leaving the entrance wide open, and filling the upper story with loose chaff in a sack of coarse bagging.

DOOLITTLE'S NEW MODE OF FORMING NUCLEI.

Doolittle now, the world must say,
Is truly an honest man;
But in all his dealings with the bees,
Has a most laborious plan.

But when I want to fool about
A lion's secret lair,
I always make a point to know
The lion is not there.

Just how it is, or comes about,
I do not wish to say;
But the lion and I are always there
At a different time of day.

So I'll say nothing about him now,
But leave till another day
The funny things I'll show you—
(When the lion's away).

But I can make a side remark,
And have just time to say
(While the lion is otherwise engaged
And looking another way).

That I went to work to make a swarm
As Doolittle told us to do;
And I took a box and wire screens,
And I took a funnel too.

So I shook the bees into the box,
And got the queen in her cage,
And so I was "armed, all cap-a-pie,"
As directed by the sage.

And here he says to jar them well—
To knock them up and down
(May be I've got it a little mixed),
And kick them round the town.

Then roll them down your cellar stairs,
For they need a little rest;
And dark and cold let the cellar be,—
Twill suit the bees the best.

And when three hours have passed away,
As three hours sometimes will,
Why, jerk them out and jar them more,
Or roll them down the hill.

Now you must open your little door,
And let the queen run in;
And now to roll about and jar,
In earnest you begin.

I had no cellar that was dark and cold,
But I had a mountain-side,
And I thought I would jar them all at once,
And thus much labor save.

So I climbed with them the mountain-side,
When every thing was still;
And, hoping they would reach the cave,
I dashed them down the hill.

From rock to rock they bounded on
From brake to bush they ran;
Such a jarring, no bees ever got
Since this wicked world began.

I bounded down the mountain-side,
I shouted out with glee,—
"This is the way to make a swarm—
Doolittle's the boy for me!"

When I got down by the creek and cave,
There was neither of them there;
For I saw naught but a rushing cloud,
And a roaring in the air.

But a thousand spears dashed in my face,
And into my arms to boot;
Oh how I yearned, just then, to see
Doolittle or Amos Root!

Why didn't you warn us, once for all,
O sage of the hive and pen,
Not to take them up on a mountain high,
And dash them down again?

When you wish to make a colony,
And thus increase your stands,
Don't fool with boxes and wire screens,
Funnels, and old tin pans.

But take two combs of brood and bees,
Or you may take but one.
And a larva-comb, not three days old,
And your job is nearly done.

So now you can go to other hives,
And take three combs or more,
And carry them to your nucleus hive,
And shake them at the door.

The baby-bees will all run in;
They have no wish to roam.
While the others that are old and gray
May scatter and break for home.

You may give them now a virgin queen,
Or give them but a cell,
Or a laying queen you may give to them
The next day very well.

Why didn't you warn us, once for all,
O sage of the hive and pen,
Not to take them up on a mountain high,
And dash them down again?

San Dieguito, Cal.

J. P. ISRAEL.

THE GALL-MITES THAT INFEST PLUM-TREES.

ALSO SOMETHING ABOUT MITES IN GENERAL.

A FEW days since I received some plum leaves covered with galls on the under surface. They came from F. A. Snell, of Milledgeville, Ill., who writes that they are very abundant on some wild plum-trees in his yard. He asks whether there is any danger of their attacking the leaves of his tame plum-trees. I at once recognized these galls as the excrescences formed by the gall-mite, a species of *Phytoptus*. These are injurious to the trees which they infest; and as the wild and cultivated plum are so closely related there must be danger that any insect which attacks one will also attack the other if in the vicinity.

The galls are on the upper side of the leaves, and are hairy, teat-like processes, often so crowded as to be in clusters of five or six in a place. They are yellowish or brown in color, though the color may have changed somewhat, as the leaves were considerably dried up. The leaves appear as seen in

FIG. 1.

Fig. 1. These galls are often on the under side of the leaves, so that the mites can leave the galls and pass out to a new place on the leaf, where by irritation a new gall is formed. The mites which, for these galls, are so minute that they are hardly visible to the unaided vision (they are oblong, Fig. 2), have four feet and four pairs of hairs on the body. These mites lay eggs in the galls, which produce other mites, and thus the galls become very numerous during the season.

It is of more interest to bee-keepers to know that our maples and basswoods suffer from species of *Phytoptus*. *Phytoptus abnormis*, Garman, attacks the basswood. *P. quadripes*, Shimer, the soft maple, and *P. acricola*, Garman, the sugar maple. A soft maple in our college apiary is badly attacked by these mites.

FIG. 2.

These mites, as will be seen above, have only four legs, while all other mites (mites are the lowest order of the sub-class *Arachnoids*) have eight legs. There are many mites of interest to us. The sugar and cheese mites work on the articles of food which gave the names. The itch mite causes the pustules on the hands, usually between the fingers of persons suffering from that disgusting disease.

The red spider is a species of mite, which is often very injurious to house-plants when kept in very dry rooms, and to evergreens, and other plants and trees in very dry seasons. Frequent and copious drenchings with pure water will usually destroy these red spiders.

The remedies for the *Phytopti* are sprinkling with sulphur, and picking and burning affected leaves, or burning the entire plants and tree. Picking the leaves is the best plan, if commenced as soon as the galls are seen.

A. J. COOK.

Agricultural College, Mich., June 13, 1885.

FALSE STATEMENTS IN REGARD TO THE HONEY BUSINESS OF OUR COUNTRY.

As a protection to our bee-keeping population, we propose in this department to publish the names of newspapers that persist in publishing false statements in regard to the purity of honey which we as beekeepers put on the market. When any paper will correct the matter publicly, with suitable apology, the name will be dropped. Any of this article will be mailed to the editor of any paper giving place to such statements, with a written protest, before the name of the paper is given. After the lapse of a small time, if the matter is not corrected we will keep a standing notice to warn the people at large that said paper does not scruple to give publicity to this class of falsehoods.

IN an article published in the *Republican*, of Westfield, Chautauqua Co., N. Y., we find the following. The article is on bee-keeping. It is signed A. M. Williams, and is credited to the *Examiner*, of New York. After telling how to keep bees, Mr. Williams winds up as follows:

Bees will carry into the hive almost any kind of sweet, and in this way glucose can be and is introduced into the hive and sold as cap honey. This is one kind of fraud not easy to detect. The greatest amount of this adulteration is in the honey that is sold in liquid form, and probably the largest part of such honey the bee has never seen.

Now, then, I should like to ask Mr. Williams, why that last clause? By his using the word "probably," we should infer he really does not know much about it. The article he writes shows he does not know much about bees. Well, if he does not know much about the honey in the markets, why should he guess that the largest part of it was never seen by honey-bees? Does he judge by the way he manages his own business, or by the way the people usually do with whom he is personally acquainted? Has it got to be so that a reporter can not expect to have his articles read unless he puts in a strong sprinkling every now and then to the effect that all men are frauds, cheats, and liars? I have personally examined the honey offered for sale in our cities, towns, and villages; and as a rule I have found it honest, and of fair quality. The only adulterated stuff I ever got hold of was in some tumblers from C. O. Perrine, and that was a good many years ago. Of course, there were all grades of honey shabbily put up; but even this has always been, so far as I could find, the product of the bees, and nothing else. Thurber's comb honey in glass jars, of course, has been put upon the market to some extent, with corn syrup surrounding the comb, to prevent granulation; but I believe this has had small sale, comparatively, and the price charged for it has always been more than is usually asked for pure honey.

AUTOMATIC SWARMING.

A REPORT OF SOMETHING ALMOST A SUCCESS.

GLEANINGS is at hand. Many thanks. I think it is a great medium between bee-keepers, as they all get each other's ideas through its columns, thereby rendering great assistance to one another. I notice on p. 380, June 1, 1885, Mr. W. J. Farriss speaks of a swarm of bees hiving itself. Well, that is not strange to us bee-men in this part of the country, for a man here has invented a plan that causes the swarms to hive themselves in almost every instance. Nearly every bee-keeper has been very successful with it here. Some have not failed in a single instance. Some failures have been reported, where the queen was not able to fly from the old hive to the new one. I know many will doubt this, as they did here until it was proven to them beyond a doubt.

Your smokers are wonders to the people here, and they please all who see them. I think there will be a good many bought here next spring.

F. C. MORROW.

Wallaceburg, Hempstead Co., Ark., June 26.

Friend M., this matter has been discussed for a good many years, but nobody has ever yet accomplished any thing of sufficient importance to have it retained, in the way of inducing bees to swarm and hive themselves. We should be glad indeed of further particulars in regard to your neighbor's invention. If the man manufactures the hive or the device for doing it, let us hear from him; but if it is something for which he sells "rights," I do not believe it will pay us to follow him further.

NATIONAL BEE-KEEPERS' UNION.

ARE BEE-KEEPERS AND WOOL-GROWERS ANTAGONISTIC?

PERHAPS the simplest way of introducing this matter will be to give the following extracts from the *American Bee Journal*:

IS THE LAW AGAINST BEE-KEEPING?

I am defendant in a case which is causing me some trouble and annoyance. For the last four years I have kept a lot of bees some two miles or more from my home lot. They are one-half mile back from the main road, where lives a man who has kept 100 or more of blooded sheep. He has sued me in the Circuit Court, having his damages at \$500; alleging, in his complaint, that his pasture is mostly white clover, and that the bees came in countless hordes, and drove his sheep from the pasture, and that they grew thin, and, in consequence, he has lost many during the winter. He asks that he be given \$500 and I pay the costs of the suit. He has engaged two smart lawyers to prosecute the case.

This, no doubt, will appear to many childish and absurd; but to one that has a costly suit to defend, coupled with poor health and plenty of cares without it, it is no laughing-matter. My excuse for stating the matter is, that it is of general interest. Our county papers have made mention of it, and it is already widely copied in other papers as a novel case, and it will be a "test case" also. Should the case go adversely, through ignorance or prejudice, it will open the door for more suits of the kind, and soon every bee-keeper would be at the mercy of any one owning a one-half-acre of clover, though he might own acres of his own.

My opponents claim that they have a precedent in a sheep and bee suit somewhere in the State. Of course, we do not acknowledge that our bees have ever injured the sheep in the least, and we feel that experiment, science, and common sense will bear us out in this assertion; yet this case, like every other one, has its adherents *pro* and *con*.

The simple fact there is a case on trial makes some believe that there is something in it.

In relation to this suit between my neighbor, Mr. A. J. Powers, the plaintiff, and myself, the defendant, I will say that I have had no quarrel with him, except in this matter, and I have got shy of this suit, and told him that I did not wish to waste any money on it. I offered to leave it to referees, telling him that we might get some disinterested parties and let them investigate and decide for us. But he would not; he said that he wanted it decided whether I or he owned the farm on which he lives. If I owned it he would move off and let me take possession; if he owned it he wanted the use of it. This is no new thing as far as theory or threats are concerned; it has been threatened for years, and more suits of the same nature are talked of, if this one goes to please the plaintiff.

I do not want the readers of the bee-journals to infer from the foregoing that I am poor, friendless, or forlorn, and in a heathen land; for we have good people here, and a fair share of intelligence. I have many friends, and can give as reference many of the best men in our county. If any one wishes for confirmation of what I have written, I am not afraid to have them write to Mr. Powers himself, asking him whether I am a man of peace and truth.

In conclusion I will say that I have supposed that Mr. Powers has had some instigators, and was encouraged to commence this suit. His lawyers have told him that bees are stock, and that we would be obliged to restrain them as such. They know full well that if we are obliged to do this, it will be the death-blow to bee-keeping. I had resolved to fight this matter to the best of my ability, and I told my opponents that they could rest assured that it would be well contested through the courts of the State, if necessary. I feel that it is a case that every bee-keeper in America is interested in, and I think it is not begging to ask them to assist in the defense, as Mr. Heddon suggests in his plan, which meets my entire approbation, and would, had I no suit of the kind on hand.

S. I. FREEBORN.

Ithaca, Wisconsin.

The following is a copy of the Constitution:

CONSTITUTION OF

THE NATIONAL BEE-KEEPERS' UNION.

ARTICLE I.—This organization shall be known as the "National Bee-keepers' Union," and shall meet annually, or as often as necessarily may require.

ARTICLE II.—Its object shall be to protect the interests of beekeepers, and to defend their rights.

ARTICLE III.—The officers of this Union shall consist of a President, five Vice Presidents, and a General Manager, who shall also be the Secretary and Treasurer, whose duties shall be those usually performed by such officers. They shall be elected by ballot, and hold their several offices for one year, or until their successors are elected and installed. Blank ballots for this purpose to be mailed to every member by the General Manager.

ARTICLE IV.—The officers shall constitute an Advisory Board, which shall determine what action shall be taken by this Union, upon the application of any bee-keepers for defense, and cause such extra assessments to be made upon all the members as may become necessary for their defense.

ARTICLE V.—Any person may become a member by paying to the General Manager the entrance fee of one dollar to the Defense Fund, and an annual fee of 50 cents, for which he shall receive a printed receipt making him a member of this Union, entitled to all its rights and benefits. The annual fee shall be due on the first day of July in each year, and must be paid within 30 days in order to retain membership in this Union.

ARTICLE VI.—Donations of any amount may be made at any time to the Defense Fund, in addition to the entrance and membership fees, and the regular assessments made upon the members by the Advisory Board.

ARTICLE VII.—The Defense Fund shall be kept for no other purpose than to defend and protect bee-keepers in their rights, and in such cases as are approved by the Advisory Board, and shall only be subjected to drafts regularly made in writing by the Advisory Board.

ARTICLE VIII.—The annual fees paid by the members shall become a general fund, from which shall be paid the legitimate expenses of this Union, such as printing, postage, clerk hire, etc.

ARTICLE IX.—Meetings of this Union shall be held at such times and places as shall be designated by the Advisory Board, or upon the written requisition of ten members.

ARTICLE X.—This constitution may be amended by a majority vote of all the members at any time.

It will be seen from the above, that the object of this union, in the words of the Constitution, is to protect the interests of bee-keepers, and to defend their rights. For a copy of the Constitution, voting-blanks, etc., send to the editor of the *A. B. J.*, the

general manager, 925 W. Madison St., Chicago, Ill. Every loyal bee-keeper interested in the cause should have a copy and enroll himself as a member of the Union.

Our readers will further see, that if our friend Freeborn loses the case the bee-keepers may have a troublesome decision on record with which to deal hereafter. Let there be no half-hearted work about it.

NOT READY FOR BLASTED HOPES.

SOME WORDS OF CAUTION IN REGARD TO ROBBING, AND OTHER MATTERS.

I AM not ready to go into Blasted Hopes yet; but, on the contrary, I am more hopeful than ever before, and feel more determined to be faithful over the few things intrusted to my care, having just passed through one of the most trying winters; and when I read of the great loss sustained by many (and some of them veteran bee-keepers too), I realize that I have reasons to be thankful. Although last season's honey-crop was short, yet the 600 lbs. which was all the surplus we got from 33 colonies (spring count) was of excellent quality, being gathered exclusively from the white clover. We increased our stock to 49 colonies; lost one by robbing (by the way, friend Root, I consider robbing the most disagreeable feature in bee-keeping); we went into winter quarters with 48 colonies on summer stands; lost three in wintering; doubled back to 43, all in fair condition at present.

I am glad to see an increase of interest being manifested among bee-keepers in this vicinity, as we are being plied continually with questions regarding our way of managing bees, what hive is best, etc. You may be sure I am glad to be able to help all such as will profit by the advice given; that is, by taking a bee-journal or some good reliable bee-book, and post up by studying the matter for themselves. Yet there are many people who think the expense too great, and go blundering along in an uncertain manner, losing more each year by not keeping posted than the books would cost, besides losing the pleasure of knowing just how to go to work to achieve the most satisfactory results.

The subject of who should keep bees has been discussed at length in the journals in time past. Well, from the past season's observation I have almost come to the conclusion that no man should be allowed to keep bees unless he will post up sufficiently to enable him to handle them in a rational and intelligent manner. During the past season I was aware of two instances of persons being so badly stung as to endanger their life, and to render the assistance of a physician necessary—one, a boy about 14 years of age, was stung while assisting a man in hiving a swarm for a widowed lady. I was with him in a few minutes after the occurrence, and it was truly horrible to witness his suffering, being almost a mass of stings from head to foot. Any intelligent bee-keeper knows there is no occasion for trouble of this kind, in hiving a swarm of bees when settled on the limb of an apple-tree within 8 or 10 feet of the ground, which was the case in this instance. The other was that of a man who was stung in trying to take honey from a box hive during the drought, when robbing was the order of the day.

SARAH E. DUNCAN.

Lineville, Iowa, June 8, 1891.

MRS. CHADDOCK TALKS ABOUT WINTERING, ETC.

BEING BORN LUCKY.

I HAVE read all the articles in the bee-journals on wintering bees, and I have inquired into the losses around me, and I have come to the conclusion that neither hibernation, pollen, honey-dew, dead-air, nor chaff, have any thing to do with it. It is fate, or the star you were born under. There is no other way of accounting for the contradictory reports and opposite results.

I have kept bees for fifteen years, and I never lost a full colony till this winter. I put chaff cushions over my bees this winter, just as I always have done, and one-half my bees died. "Honey-dew?" Yes, of course, but one-half mile from me a man had six colonies last fall; he did not pay any attention to them (they are in American hives), and they had the same pasture that my bees had, and they all lived. So it was *not* honey-dew. A mile away lives an old bee-keeper. He has had bees for forty years, and he has them in old box hives; he doesn't care about keeping bees; is too old to climb into the apple-trees to get the swarms down; doesn't think there is much money in bees any way; women are afraid of them, etc. Well, now, do you suppose he lost all his bees last winter? No; he has eight or ten left. He had the honey-dew too. So it is not contracting the brood-nest, and packing, and all that, that make bees winter well. It is wishing them dead that keeps them warm.

All writers say there must be no honey left around the hives when there is no honey coming in, as it will start the bees to robbing. Mrs. L. Harrison told me that several of her colonies died in the winter of 1882, and that in the spring she was sick, and she let the other bees clean out the honey where the bees had died, and that after it was gone she put scraps and refuse honey in the empty hives, and let them eat that, and she had no robbing. Now, why did not her bees go to fighting? Simply because Mrs. L. H. was born under Jupiter or Saturn, or whatever star it is, that it is good luck to be born under.

HEDDON'S PLAN OF PREVENTING AFTER-SWARMS, AND HOW IT TURNED OUT.

I have tried Heddon's method of preventing after-swarms, and failed. My old colony faced to the east. When the swarm came out I caught the queen, turned the old hive around so that it stood at an angle of 45 degrees, and put the new hive full of foundation in the old one's place. In a few minutes the swarm came back, and I let the queen run in with them. Two days later I turned the old hive back so both of them faced to the east; four days later, six days after they swarmed, we carried the old hive to a new location, and on the eighth day they sent out an after-swarm. They alighted on a young elm, and I opened the hive and found one young queen and about a dozen queen-cells. One of them was just ready to come out; in fact, the door was partly open. I introduced to a queenless colony, and cut out all the other cells. Then I took the swarm down in a basket (tied it on a bean-pole), and they all went in. It was a large swarm, as large as many first swarms. It is my belief that, as a general thing, it will work all right, but this colony was an extra strong one, and so many young bees coming out made them feel strong and independent.

HOW I MADE BEESWAX, AND WHY I AM OUT OF THE BUSINESS.

If your "fool-killer" is at home, please send him around this way. Ahem! I had a good many old combs; and when the bees "went dead" I rendered the combs up and thought I could exchange it for foundation. I put it in a sack made of gunny, and *boiled it* and dipped off the wax that rose to the surface. After it got cold I *boiled it* again, and set the wash-boiler off and let it cool slowly. Then I took it out and scraped the propolis (or something) off the bottom, and *boiled it* up and let it cool, seven times. I thought as long as that stuff was in it, it ought to be *boiled* some more. I *boiled it* in the wash-boiler, and once a week I cleaned up the boiler so that we could use it for washing purposes. Once it boiled over and took fire, and might have burned the house down if no one had been there to put it out. Well, the more I *boiled* that wax the worse it looked, till I began to think that it was all a humbug—never had been beeswax at all, but just propolis and dirt. Finally I sent to Messrs. Dadant and asked them to send me foundation for it. Yesterday I had a card from them saying, "Your wax has been spoiled by *boiling*. You should never bring it to more than a *quiet boil*" (I *boiled* mine furiously), "and melt it only as much as needed to clear the dirt away. There will be about one-third waste in this way. When you cool it, let it cool *slowly*." I sent the wax by express, because they ordered me to; but at the time, I thought it looked as if a freight passage was good enough for it. I have written to Messrs. Dadant to know how much they had to pay on it, and I shall pay it, and next time I will send—no, I won't, there will never be any "next time" for me to render beeswax, if I can find fires anywhere near to throw it in.

Now, you need not any of you send me circulars telling the good qualities of your wax-extractors. I won't buy any of them; I am not in the beeswax business any more. There will never be any more beeswax cooked in my wash-boiler, nor on my stove, nor anywhere on this farm; not if I know it. Ahem.

Vermont, Ill.

MAHALA B. CHADDOCK.

REPORT FROM AN A B C SCHOLAR.

AND SOMETHING ABOUT THE NUMBER OF YEARS IT TOOK HIM TO GET SO HE COULD KEEP BEES SUCCESSFULLY.

IN 1871 or '72 I had a colony of bees given me that were in an old box hive, which I thought as good as any. We were much pleased with them, and thought we should soon be feasting on honey, so we fixed a honey-box on top, and waited patiently. But no honey reached it, and of course we were disappointed, and concluded it was a poor season for honey. The next spring found us without bees or honey. Supposing that the worms had destroyed them, and thinking there was no way to prevent, we concluded it was not worth while to waste time with bees. In a year or two after, we saw GLEANINGS advertised, and so, through curiosity, we sent for a sample copy, which induced us to subscribe for one year; and the information gained caused us to procure a new swarm of black bees in a Langstroth hive, which was in 1878. They filled the lower story, that season, but nothing more. In 1879 I received parts 1st and second of the A B C book; and by its instructions

we divided our colony, and being very busy on the farm, did not give them further attention, so no surplus but plenty to winter on. In 1880 we increased to four colonies, which were put in Langstroth hives, and this season gave us no surplus honey, but plenty to winter on. They were left to winter without any extra protection, and the result was, the spring of 1881 found us without any bees. By the use of movable frames I knew it was not worms this time. Some said it was the cold weather; but my bees were dying rapidly before cold weather commenced. I then purchased an A B C book complete, and read it carefully, and began to feel more interest in bees, and that it would be a pleasure to manage them according to the improved methods. In June I received three frames of brood and bees, with a fine Italian queen, from your apiary. As it set in very dry they did not do much until buckwheat bloomed, from which they filled the brood-chamber with bees and honey. The description of the chaff hive gave me a desire to test their good qualities. I received one from your factory, placed my bees in it, and a chaff cushion over them. As it was the only chaff hive in this country, I felt that I was a little ahead. They came out in the spring of 1882 in fine condition, and did well. The following season I received several pounds of surplus honey, and increased to four good colonies by fall, which were all put in chaff hives, and the spring of 1883 found them all in good condition. As this was an extra season we had plenty of honey which we enjoyed, and some to sell. By fall we had ten strong colonies and five nuclei, from which we had been learning to raise queens. We sold a few, and introduced four into our own colonies that had hybrid queens. They all raised nicely marked bees but one. We find our strain of Italians so quiet to handle that we are trying hard to keep them pure, which is a task, as there are blacks and hybrids near us on three sides.

In the fall of 1883 we placed 14 in chaff hives, as instructed by the A B C book. Four of them were three and four frame nuclei we had raised queens from. They were all left on their summer stands, as an experiment. One of three frames in a Langstroth hive with division-boards and cushion, and cushion over them, was carried into the cellar when the mercury neared zero, and returned when it moderated, which caused several trips; frequent examinations through the winter found them in good condition, and the first of April, 1884, they were all doing well. The colony that was carried to and from the cellar had the most dead bees.

Last season was not very good for honey. White clover was worked on but a short time, and but very little basswood bloom in this section. We received only about 500 lbs. of honey—half comb and half extracted—and increased from 15 to 21. In the fall of 1884 we put them in shape for winter, as follows: 14 in chaff hives, prepared as winter before; two in Langstroth hives on six frames, with chaff division-board on each side, and cushion above; five of four frames, in L hives, prepared as last two. All left on summer stands came through all right until the middle of March, when I discovered one of the weak colonies dying very fast, and in one week were all dead. The others came through safe, and made a fine start on sugar maple, fruit-bloom, and black locust. The white clover is not furnishing much honey yet, although there is plenty in bloom.

A REPORT ON CARP CULTURE AS WELL AS BEES.

My carp are doing finely. We have a quantity of young fish about one inch in length. Those that are one year old make a fine showing when fed, which are from 8 to 12 inches long. We seined our pond in April; caught 19 old ones that weighed 6 to 7 lbs. apiece; sold six of them and 125 small ones 6 to 10 inches. The old ones were 20 to 24 inches in length. We put 7 large ones in a pond built last fall, where our small ones are.

Springboro, Ohio.

W. H. CARPENTER.

Our friends will notice from the above the length of time it took an average farmer to get properly hold of the subject of bees so he could make it a safe and paying investment. It also illustrates pretty well the reason why our ventures in these industries sometimes pay and why they do not pay. You see, it all depends upon getting acquainted with our business, and managing understandingly. Another point comes in right here. If a man has learned to succeed with bees, he will be pretty sure to succeed with other things—carp, strawberries, or whatever he may take a notion to go into; because the same fundamental rules that give success in the one case are pretty likely to give success in another.

SWARMS WITH CLIPPED QUEENS.

FRIEND DOOLITTLE TELLS US HOW TO MANAGE THEM.

SOME apiarists seem to think that a colony having a clipped queen causes much trouble when swarming, and I note an expression in a late number of GLEANINGS which looks as if the editor of that paper held the same views. This seems strange to me, for I would rather care for three swarms whose queens are clipped, than for one where the queen is not clipped. Believing that all can not understand the best plan of managing such swarms (else the above idea would not obtain), I will give my plans, with a view of helping the many who practice natural swarming.

I first get a light strong pole, from 10 to 18 ft. long, according to the height of the trees near the apiary, and to the top of this pole I wire some mullein-tops of last season's growth. These should be left open, and should reach up and down the pole eighteen inches, so the bees can get a good foot-hold, in order that they need not keep dropping off when clustering upon it.

We next want a round wire-cloth cage, about two inches in diameter and eight inches long, with a permanent plug in one end, and a movable one in the other. Having attached a wire to one end of the cage, we are ready for the swarm. Seeing one issuing I step to one side of the front of the hive, and stand about five feet away, so I can take a view of the whole front of the hive, and two or three feet of the ground in front of the entrance, at a glance, when, if the queen is out, I almost instantly see her; and if not out I see her as soon as she issues. I used to get close to the entrance to look for her, and often looked a long time before I found her, owing to the short range of vision which contracted the breadth of the field seen at one time. When the queen is seen, put the open end of the wire-cloth cage down so she can crawl into it, which she will at once do, when she is secured by putting in the mov-

able stopper. By means of the wire, attach the cage to the mullein-tops, and hold the top of the pole in the midst of the bees; for by so doing they do not scatter over a large field, as does a swarm not having a queen with them, and they will often alight on the pole besides. If they begin to alight on a tree instead of the pole, place the bunch of mullein-tops close up under them, when they will at once begin to cluster on it. After a part are clustered on the pole, push the pole up and out of the limbs, so that no leafy twigs hit it, and leave it until they are all clustered, when you can carry the swarm and hive it wherever you choose. If the place of hiving is within four rods of the alighting-place I wait for only a few bees to get clustered on the pole when I take it to the hive and start those I have to running in, when the whole swarm will come. In this case it is well to cover up the old hive with a sheet, or close the entrance to it for a short time, as a part of the bees may go to the old hive before they hear the call of "A new home is found!"

As the season advances I use the Heddon plan (as given in GLEANINGS for June 15), of working the hives to prevent after swarms; and here especially is a clipped queen a decided improvement over those that are not, Heddon to the contrary notwithstanding. Proceed to catch the queen as before; and as soon as you have her, get your new hive and bring it to the old stand. Now wheel the old hive half way round so it faces in the opposite direction, and place the new hive just where the old one stood, when I place the cage, with the queen in it, endwise to the entrance, one end being within an inch of the center of the entrance. The bees from the field which have, during this process of changing hives, been hovering around, now find the queen, when they set up a hum and fan their wings, which soon attracts the swarm, that comes pouring into the new hive by the thousand. I now take the cage, giving it a little jerk to shake the bees off from it, when I remove the stopper; and as the queen runs to the open end, hold it down to the entrance, when in she walks as nice as you please. If two or more swarms get out at once I always let them alight on the pole as first given, when I can carry and divide them as I please in hiving.

When I am away from home, Mrs. D. or some one else watches the apiary, simply noting the hives which swarm, so as to tell me which they are when I get home. If the queen does not get back, a look about and near the hives always reveals her in a little ball of bees, from the size of a butternut to that of a goose-egg. In short, the clipping of our queens' wings is one of the improvements of the age, second to none of the advancements made within the last twenty-five years, in the opinion of—

Borodino, N. Y.

G. M. DOOLITTLE.

I am quite familiar with all you mention above, friend D.; but when we worked entirely with clipped queens, a great many times we did not find them at all; and at other times, as you may remember, the swarm would unite with some other swarm having perhaps a virgin queen, and then they would all go off together. We have also practiced putting the queen in a cage and tying her on a pole, with different kinds of arrangements on the pole to induce them to cluster; but while some swarms clustered around their queen almost immediately, as nice as could be, a good many would persist in clustering almost anywhere *except* near that caged queen.

He that is faithful in that which is least, is faithful also in much. LUKE 16 10.

MYSELF AND MY NEIGHBORS.

Discretion shall preserve thee, understanding shall keep thee.—PROV. 2: 11.

YOU will remember, little friends, I did not get through with my talk about discretion last month. We often speak about children arriving at the age of discretion; but I showed you by some plain examples that even an old hen has some degree of discretion. She decides what is best to do under certain circumstances, and decides with quite a little wisdom. Well, if I am right about it, children also show discretion and wisdom, and a sort of judgment, at a very tender age, though often it requires some special circumstance to bring out their wisdom and judgment; for as a rule, parents and friends take the responsibilities from their children.

A few days ago Huber slipped while going out of doors, while somebody was holding his hand, in such a way as to sprain his wrist; and it was a pretty bad sprain too. I suppose, for he cried a long while, and almost screamed when anybody attempted to examine the wrist. He finally almost set up his authority, and decided it should not be touched—not even by mamma. At this crisis the matter was carried to papa, and his superior (?) judgment was called upon to decide. I decided with Huber to let the wrist alone, and I also decided we did not want any doctor. This last decision almost created a war in the camp. It brought on a pretty hot discussion, any way, and papa gave his reasons as follows: His

arm is not broken, because the bones of a baby do not break; they are too soft. The shoulder is not out of joint, because he does not say a word against having his shoulder handled. Neither is there any thing the matter with his elbow, for the same reason. The difficulty is, therefore, necessarily located in the wrist; but it is not a very serious one, for he can move his fingers. The bones of the wrist are not out of place, because Ernest felt of them when the accident first happened, and satisfied himself that the injured wrist was exactly like the other wrist. If one of the eight bones was out of place, Ernest would have discovered it; for he is a boy of pretty good judgment and discretion. He has been at college, you know. Maud insisted that this was too serious a matter to jest about; and if Huber grew up crippled for life in one of his hands, we should all of us repent most bitterly that a doctor was not called for at once. A doctor would have given him great pain by going over exactly what Ernest had done, and the wrist was now swollen, and so sensitive that he almost screamed if it were touched even by mamma. He just lay in his crib all day, and kept still; and when he slept he slept without turning over and "raising Ned" as he usually does. He had decided with what baby sense he had, that the proper thing was to keep still, and let it get well. I told him that God made the little wrist and little hand, and that God would fix it in a few days, if he knew he were real careful and keep still. God knew how, for God made the thunder, and furthermore,

God loves Huber. These words seemed to give him comfort, and he would sometimes vary the question by saying interrogatively to me, "God loves baby?"

"Yes," I assented, "and God will make the little hand all well."

Twenty-four hours passed, and no change for the better. In fact, it was *more* painful. The women-folks clamored for a doctor again. I recommended waiting another twenty-four hours. By this time, with the aid of the sling which mamma fixed, he was able to get up and walk around; but that sprained wrist was his property. No one had any right to touch it; in fact, he preferred not to talk about it. I asked him in the morning if it was better. He replied with two short words, "No! worse." This aroused a big laugh among the members of the household, and even brought a smile to the corners of Huber's mouth. On the third day he used it enough to hold a piece of bread in his fingers, keeping it still in the sling, and after about four days he announced in the morning with much rejoicing, "Paddy all well; oh goody! goody!" He came to me to tell me about it; and after saying that God had made it well, just as I said, he kept repeating, "Nice God; made baby's paddy all well." His mamma rather objected to his familiar way of expressing his praise to God; but I told her it was all right. It was the best way that he knew of for giving thanks, and it was surely acceptable to Him who fashioned these little household treasures. The wrist is perfectly well now.

Perhaps I might remark here, that such a sprain is more painful than a broken bone. Had we sent for a doctor, the doctor would have had the credit; or if we had put on some patent liniment, *that* would have had the credit. Huber's mother did try to put on some arnica, but he objected; and I suggested that arnica was probably just as good as warm water, and no better. Then we had a discussion in regard to this and that medicine. I replied that they would have to excuse me for having but little faith in arnica or camphor, and every thing of the sort, because I could not understand how anybody discovered the virtue of arnica, even if it had virtues. There are thousands upon thousands of herbs and roots in the fields and woods; there are also a great multitude of diseases. If there were only one disease afflicting the human family, it might be possible to try all these things one by one, in the treatment of said disease; but when it comes to trying all the herbs and roots, to say nothing of minerals, on all diseases, the number of tests to be made would be like the sand on the seashore. And then on top of it all, people usually get well where you do not do any thing. How, then, are we *reasonably* to decide that it was arnica or camphor that performed the cure? God gives us reason, judgment, wisdom, discretion, or whatever we may call it. Are we using that good judgment which he gave us, or are we trusting to what we have heard folks say, and to superstitions handed down?

Let me use an illustration. If you take a dozen cards and tear each one in two in the

middle, then shake up the 24 pieces, you might, after a little trying, pick out two pieces that would match; that is, you could find a pair of pieces that would fit together just as they were before being torn. If you do not know how long it will take, try it. Now, instead of a dozen pieces, suppose we take a hundred. It might take you half a day to match even one card; but suppose instead of a hundred you make it a thousand, or even ten thousand; instead of putting the pieces in a heap, scatter them over the fields. Is it at all likely that you would ever get two pieces that would fit as they were originally? How, then, did anybody ever find out that *arnica* is good for a *sprain*? Our stenographer suggests, that as arnica is a poison it probably has some effect one way or the other on the flesh. But plenty of things are recommended as remedies that are not poisonous at all. Take the remedies for bee-stings, for instance. Enough are recommended to fill a book; and yet I think I can prove conclusively to anybody who will use his good judgment and reason, that not one of these remedies that has ever been recommended has any effect on the sting, one way or the other.

□ Now, it may be, little friends, that Uncle Amos is a little extreme in his views, and may be you will exercise your judgment and good sense in not accepting all his teachings, and that is just what I want you to do. Use the discretion and wisdom and understanding that God has implanted in your little hearts, exactly as Huber used his discretion and understanding when he insisted that nobody should touch his sprained wrist.

A TRIP TO THE HOT SPRINGS OF CALIFORNIA.

Also quite a little about Bees.

FROM AUNT KATIE HILTON.

DEAR CHILDREN:—Do you want to take a trip with me to the Montecito Hot Springs? If so, come along, for I am going. Here comes the four-horse stage. Hurry up, for we have sixty miles to go to-day. There, now we are all fixed, and off we go. Isn't it delightful? The easy rocking of the stage, the nice cushions at our back and on the seat, soften all jolts, and the balmy air of the morning, with the occasional glances of the grand hills, make us feel happy, even if we have been on the sick list, and still feel weak.

"Why, where are we going?" says one, as the stage seems to be standing almost perpendicularly. Soon the splash of the horses' feet in the water tells us we are crossing the Santa Ynez River. The chicks look out and catch glimpses of trout in the rapid stream. Many brooks come from the mountains, and the trout come down with the water. This delightful ride after an early breakfast makes us hungry, and we partake of the lunch put up by thoughtful friends; and, refreshed by a drink from the first brook we come to, we bound along until eleven o'clock, when we stop for dinner. It is pretty early, but it is now or never, so we pile into the little "building and rest and eat until we see the fresh horses being put on to the stage. We climb into our seats, and away we go. Now we are

going up the mountain. The horses can go only on a walk; so we peep out of the door, first on this side and that, trying to see all the wonderful sights we have heard existed along the road—deep cañons, so near the road that it seemed only marvelous that any one could drive four spirited horses along without tipping over the stage, and many other startling things greet our sight; but, up we go, and soon we hear a sweet sound breaking upon the stillness that we had all fallen into within the stage. It proved to be the voice of an outside passenger singing, "Jesus, lover of my soul." Soon the deep bass of the driver chimes in, and the music charms us all until even the baby catches the spirit, and he calls for more. When the hymn is ended, so the mountain-side echoes with song, and as the air gets lighter the nearer the top we get, even the weak-lunged ones try their voices.

Oh! what is that? Well, I declare, if here isn't an apiary away up here on this mountain. One, two, three, four. Oh! I can't count them. I wonder how many hives there are. "I should judge about 50," says one; and see! there is a man looking up, kind o' wishful. I wonder what he wants.

"Mail!" sings out the driver, and three papers whiz through the air, landing on the grass by the man, who waves his hand for thanks, and we disappear from his view around a sharp bend. What lovely flowers! I never saw anything like them before; did you? They grow only in high latitudes.

Here we are at the next station. Out we all tumble, to get a drink from the stream which is pouring from a spout which comes from the mountain-side. How fresh and good it tastes! A man comes along with a frame of comb in his hand, and, looking in the direction from which he came, we catch a glimpse of some hives between the brush that lines the road.

"Do bees do well up here?" we ask the man.

"Yes, very well generally, but we are afraid it will be too dry this year."

"But I suppose you, like many others in California, made enough last year to pay for two years' labor, did you not?"

"We did pretty well," was the cautious answer.

"How near are we to the top, driver?"

"Oh, about a mile."

"Then we shall see Santa Barbara," says one devotee; "and the sea," says another; "and a lovely picture of both," says mamma; and, sure enough, when we do get to the top, what a picture the valley and ocean do make? But we could only just take one glance, for on we go, bounding over the rocky road, which is steeper on this side than the other, and quite rocky. In one place the rock is so smooth that places have been cut for the horses' feet, so they would not slip down.

Now we have got to the bottom, and are bowling smoothly along between orchards and grain-fields, and then we chatter into an air so laden with the perfume of honeysuckle and roses that we crane out of the door, thinking we surely are in Santa Barbara; but we are still a mile away. But, here we are now. Why! see those three rows of roses and fan-palms right in the street. Yes, the proprietor of the Arlington Hotel put them out, and has them kept in order. And, see! there is the hotel, with its lovely green lawn dotted over with strange trees and lovely flowers. Yes, and see that deer. "I see two," shouts a little voice. Sure enough, there are some deer among the trees, looking as

contented as you please. We stop at the postoffice, where the driver throws out five large sacks of mail, and then on to the Morris House, where we are treated so well that we feel quite at home. Even the little ones are charmed, and go trooping up the stairs, laughing and talking so excitedly that we have to admonish them to be more quiet, because they might disturb some one. How we did enjoy our supper that night!

"Why, mamma, here is a swarm of bees," shouts Ernest, pointing up to the corner of one of the wings. Sure enough, we could see myriads of the little rogues coming out from the cornice of that great building, right in the heart of the city; and a few days after they swarmed, and went into an empty box in the yard, so Mr. Morris has to be a bee-keeper, whether he wants to or not. It seemed symbolical—a hotel is much like a hive of bees; but the proprietor is something of a king instead of a queen, but is quite as indispensable, and it depends as much upon him as to whether the hotel is a success as it does to the success of the hive, with the kind of queen that is within.

Well, how are we to get to the hot spring? Tomorrow is the regular day for the stage; but we do not want to wait, so we get an express wagon to take us up. The people of the city have made a law that bees shall not be kept in the city; but the bees do not read the papers, and they have not heard about the law, so they keep trying to be owned all through the place, and I do not blame them; for if I were a bee I should want to live there too.

Just as we were getting ready to start we heard a commotion on the main street, and, looking out, we saw a swarm of bees alighting upon the tongue of a great dray-wagon. Such a scrambling as there was to find a man who could hive them! They managed to get the horses unhitched before they all alighted, and then a man came with a box and brushed them into it, and the wagon was pushed by hand until quite away from the bees. No one was stung; but what might have happened if any naughty bees had settled on those horses, none can tell.

Here we go, past fields of pampas grass, walnut-trees, and fruit-orchards of all kinds—past the city of the dead on one side, and the orchard and buildings of the poor-farm on the other. Then up, up we go, till it seems as though the horses can not possibly climb any more; but they are allowed to rest awhile, then on we go up the steep rocky road. The driver stops his horses, and jumps out to get some wild blackberries that he saw, and we also get out and partake of the feast that Nature gives us. Then on again up worse and worse roads, till finally we espy a house that seems to hang upon the steep hill-side, like a canary-cage on the side of a wall. The panting horses are wet all over with sweat, and we are glad for their sake that we have arrived.

There are two large springs coming from the side of the mountain, and bath-houses have been erected. The one at the upper spring is generally used by the ladies, and the lower by the gentlemen. We were soon ready for a bath, and felt well repaid for the trouble of getting here; but we felt a slight headache, from the altitude, we thought, but hoped it would soon pass away, as we had made arrangements to stay a week; but we had to go back next day, for our head got to aching harder, and we were so dizzy that we did not dare to walk along the road that winds like a gray thread among the

bushes of the mountain-side. The water is so hot that it is uncomfortable for a few moments; but one soon gets used to it; and as it is soft, one can use soap and not feel the stickiness that is left by some of the mineral springs. Some enjoy the rareness of the air, but I was told that a great many came who had to leave sooner than they desired, on account of headache.

There are quite a number of apiaries along the foot-hills between the mountains and the Montecito, but they expect to be driven away soon, as the orchards keep creeping up the hill-sides. Fruit does so well there that every one puts out trees as soon as they get the land ready for them. Every one concedes that bees will not injure the fruit until broken; but the yellow-jackets start it for them, and then they are declared a nuisance, and so they have to go. I have got home safe.

Los Alamos, Cal.

KATIE HILTON.

Why, bless my stars, Mrs. H., how your letter does make me want to go and visit my brother in California! And do you really find bees everywhere? I should think it would be a grand place to go. I shouldn't have the headache, you may be sure; and those hot springs—what a grand place to raise carp! You know they revel in warm water. Our "stenog" says that it is too hot; but, bless you, don't they have cold water somewhere around that could be mixed with it? and then wouldn't that hot water be grand for conservatories and tropical plants? Before I read your letter I thought I was perfectly happy with what was to be found on my own 18 acres; but now I am in quite a fever for a hot spring.

SUNDAY SCHOOLS AND BEE-KEEPING.

AN OLD FRIEND IN A QUANDARY.

A FRIEND stopped by the side of my buggy, where I sat waiting, a few evenings since, for the mail to be distributed.

"Next Sunday, you remember, we organize a Sunday-school in our own church. We may depend upon you for one of the teachers?"

"Oh! not as a regular teacher," I replied; "I will do as I have done in the past,—take the place of any absent teacher, if need be, when I am there. But, you know the bees."

"Yes," she returned, with a little smile, "I was afraid they might stand in the way. But is it quite right? Should they keep you from all good things—church services, the Sunday-school, the aid society?"

"You are no bee-keeper," said I, "and so I could never convince you that there is any right about it."

"Take a class in the Sunday-school," persisted my friend, "and just trust that the bees will do us well without as with you. You will be with us next Sunday, of course?"

"Yes," I returned, "if—if it be too cold or rainy for the bees to swarm."

And my friend passed on, shaking her head in disapproval.

Just then little Harry C. came whistling by, pausing a moment to unpucker his rosy lips, and wish me a smiling good-evening. I smiled in return, but I sighed as he passed on, for Harry is one of those bright boys one had rather talk to of a Sun-

day afternoon than interview the gentlest of Italians. I never see him but I am reminded of one Sunday when, in the absence of their teacher, I had taken the class of which he was a member.

"Harry," said I suddenly, as I saw his mischievous fingers creeping into the neck of the boy who sat next to him, and then reading from a verse in the lesson, "Be strong in the Lord. What does that mean?"

And Harry threw back his sturdy little shoulders, and clinched his small hands, and with proud eagerness exclaimed, "It means—it means to have muscle!"

But from thoughts of the Sunday-school I am suddenly turned by a thought of the blessed bees.

"Trust that they will do as well without as with you," says my friend. She little knows what inveterate Sabbath-breakers they are.

More than one brother bee-keeper has written upon this subject, and now will not some of the sisters, those who keep bees for profit more than pleasure, who number their colonies by tens instead of units, will they not please tell me how they care for them, or if they care for them at all, on the Sabbath? Only do not suggest dividing, or the use of a non-swarmers, these methods having been considered and rejected.

After all, I fear this is a question each one must answer for herself. And yet if any sister has a word of advice for one who loves her bees, and yet would fain leave them to themselves one day in seven, will she not kindly speak?

NELLIE LINSWICK.

My good friend Nellie, I am real glad to hear from you again, even though your letter does not tell us much about how you are succeeding with the bees during this year of 1885. It rejoices our hearts, however, to hear that you are striving after righteousness, and that you love the Sabbath-school as well as the bees.

TOBACCO COLUMN.

DEAFNESS CURED BY LEAVING OFF TOBACCO.

WHICH is the worse—tobacco, or not enough poison? I have been using tobacco for the last 25 years, so one day I all at once got the notion that I would quit using it; but, friend Root, you would not believe the success that I had after I quit using it. For the last five years I have been getting deaf. I did not know what to do. My doctor told me that I was not going to get better, and so I was alarmed at the report. I did not know what to do. An old friend of mine, William Kohn, told me that I would have to quit the use of tobacco before I could get well. I quit April 12, 1885, and to-day, June 12, I am in perfect health. Last night I happened to read in GLEANINGS that you will send a smoker to any man who will abandon the use of tobacco. Every man whom I meet on the street I will stop and tell him of my success. William Kohn says if you will send me a smoker he would also subscribe for GLEANINGS, for he says that he likes to deal with men who try to abandon the use of tobacco. I think I have carried a smoker, then, if that is the case.

MATHIAS SCHNEIDER, SR.

Alabaster, Mich., June 12, 1885.

Every boy or girl, under 15 years of age, who writes a letter for this department, CONTAINING SOME VALUABLE FACT, NOT GENERALLY KNOWN, ON BEES OR OTHER MATTERS, will receive one of David Cook's excellent five-cent Sunday-school books. Many of these books contain the same matter that you find in Sunday-school books costing from \$1.00 to \$1.50. If you have had one or more books, give us the names that we may not send the same twice. We have now in stock six different books, as follows, viz: *Sheep Off, The Giant-Killer, The Roby Family, Rescued from Egypt, and Ten Nights in a Bar-Room*. We have also *Our Homes, Part I*, and photograph of our old home-plant, taken a great many years ago. It is a picture of myself, Blue Eyes, and Caddy, and a glimpse of Ernest. We have also some pretty little colored pictures of birds, fruits, flowers, etc., suitable for trading. You can have your choice of any one of the above pictures or books for every letter that gives us some valuable piece of information.

'A chiel's amang ye takin' notes;
An' faith, he'll prent it.'

LITTLE friends, did you ever hear anybody tell about being as uneasy as a fish out of water? I suppose of course you have; and the saying has become so proverbial that no doubt you all—in fact, the world in general—will be greatly surprised when I tell you I have seen fishes out of water, and they were not uneasy either. Yes, great big fishes, almost as big as the cod fish your father brings home from the store. Do you want to know about it? Well, yesterday, when I got tired, and my brains felt sort o' muddled up, I got away outdoors. I went down through the apiary where 400 hives of bees were rolling in the clover honey. Then I went through the peas to see if they were large enough to pick. Then I helped the lima beans climb up their poles where they could not quite reach them. Then I pulled up some lettuce. We have a great lot of it, and it will not sell now, on account of strawberries being five cents a quart; so I gave some of it to the Jersey cow. She seemed to think it very good, and would probably have eaten the whole of it if Mr. Somers did not give her so many other nice things to eat every day. Well, the carp-pond is right near the Jersey cow, and this same carp-pond always rests me better than almost any thing else. Mr. Somers had mowed the grass nicely along the steep bank on the north side, so it was pleasant and cool down there, and I stepped along very carefully to see if I could not catch the carp at some of their tricks, without their hearing me.

Pretty soon I heard an awful splashing. It sounded as if a small pig were rooting around, making the water splash. You may be sure I dropped down close to the ground, and crawled up on my hands and feet; and I was rewarded by seeing a great whopping fish out of the water, and not un-

easy either. He was up among the roots of grass, nosing and rooting about like a pig. His tail was partly in the water some of the time; but as he squirmed around a good part of the time he could be said to be, truthfully, to all intents and purposes, out of the water. Pretty soon he, with a dextrous flop of his tail, slid back into the pond again, and then went prowling along with his great fins sticking clear above the surface. Pretty soon he backed up and shot forward with such force that he came clear up on the grass in another place. After digging around in the grass roots as before, making quite a chanking and blowing, he flopped back in again. This he repeated clear around the north edge of the pond, coming up every three or four feet.

The grass and water-plants along this edge are growing very luxuriantly, for it is a sort of sandy loam, and these succulent roots seem to be what the fish are fond of. Before he got around, a smaller fish attempted to do the same thing, but he could not manage it so well. The sight was so wonderful and astonishing to me that it almost made my hair stand on end. The beauty of the sight, as his gorgeous scales glistened in the sunbeams, showing different colors as he twisted about, was beyond any thing I can describe, and his motions seemed natural and graceful—quite different from that of frightened fish when we pull them out on the grass. I wonder if the rest of you enjoy such sights of nature as these as I do. Why, it seems as if these humble creatures, studied when they are not aware that any eye is upon them, were almost enough to give us glimpses beyond the veil that separates us from the unrevealed world beyond. It seems to me as though I were catching glimpses of the great Father, by studying his creatures. Sometimes these great fish came up and gazed back at me, as if they, too, wondered what we were for and where we were tending.

As I started back to the office to take up my work again, my heart was filled with praise and thanksgiving—yes, thanks for the fish as well as for the bees. Now, then, what have you to tell me this month in your little letters?

CARP AND BEES.

We have a carp-pond that covers 1½ acres of ground; we have 500 large carp in it, and 170 small carp. Pa paid \$4.00 a hundred for them. We lost 15 swarms of bees last winter, and we have 8 left now, 6 very weak.

MARY E. COOK.

Manfield, Ohio, May 12, 1885.

HOW TO MAKE A CHEAP OIL, TO BURN IN A LANTERN.

To make signal oil. Take two qts. of lard oil and add one quart of coal oil. Signal oil is used to burn in lanterns. If this is worth a book, send me *Our Homes*, part second.

JOHN CRAIG, age 13.

Armstrong, Kan.

I suppose the above would do for some kinds of lanterns, John; but as most of the lanterns nowadays are made to burn coal oil, or kerosene, I should think so much lard oil wouldn't work very well. Besides, lard oil is quite expensive.

A STRING OF LETTERS FROM THE LINK CHILDREN, AGED 12, 10, 8, AND 6 YEARS RESPECTIVELY.

CARRIE'S LETTER.

My pa keeps bees. We had four months of day school, and I am going to Sabbath-school. We got one of your extractors, and a bee-brush and a honey-knife. We like them very much. We take GLEANINGS, and I like to read the little letters. I like honey very much, but I don't like to get stung by the bees. My pa makes his own hives.

Preston, Minn., Mar. 6, 1885. CARRIE LINK, age 12.

BARBARA'S LETTER.

My pa keeps bees; he has 37 stands in the cellar now. We extracted about 180 pounds. I like honey. I have four sisters and two brothers. My ma hives the bees sometimes when pa is not at home. The bees sting me sometimes. I go to Sunday-school. I read in the Third Reader. We have the hives standing in the garden, under the apple-trees; the apples fall on the hives, and the bees fly out and get mad.

BARBARA LINK, age 10.

HENRY'S LETTER.

I saw the other little boys and girls writing letters to you so I thought I would. I go to day school and to Sabbath-school. I read in the Third Reader. We have about 400 lbs. of box honey.

HENRY W. LINK, age 8.

SARAH'S LETTER.

I like honey, but I don't like to be stung. I go to day school. I read in the First Reader, and I go to Sunday-school. We did not get much honey last year. We got only 165 boxes from 65 hives.

SARAH LINK, age 6.

FREDDIE'S LETTER.

My papa has bees. I like honey. Papa takes GLEANINGS. I like to have papa read the little letters. I go to school, and when I come home I bring the cows for my papa. I like to see my brother work with the bees; he looks so funny with his hat and veil on. I should like to see your fish-pond.

Stottville, N. Y. FREDDIE W. ENGEL, age 7.

LENNIE'S LETTER.

My papa has 10 swarms of bees, and they are doing well. Mr. Root, I am a cold-water boy. Do you think I write well enough to have Ten Nights in a Bar-Room?

LENNIE F. GREEN, age 10.

North Newburg, Mich.

Yes, Lennie, you write a very nice hand. The letters are all very plain, and the words are all properly spelled.

HOW CAREY'S FOLKS MADE A BOAT.

Our bees are doing well. We have three hives of Italians. We like GLEANINGS very much. We have a boat. We got a pine log and cut it out, then pitched it. We have much fun riding in it. We are thinking about making a carp-pond. The way we hive bees is to get a light box with a lid, and put it under them, and take an ax, if the limb is low, and shake them off.

CAREY TAPLEY.

Columbus, Miss., Feb. 28, 1885.

41 IN THE FALL, AND 40 IN THE SPRING.

My brother keeps bees. Last fall he put 41 colonies into the cellar, and came out in the spring with 40, although the temperature often went down to 24 degrees below zero. Our bees are mostly Italians. In the spring of 1884 we had 20 colonies, and increased to 41 and got about a ton of extracted and comb honey. The most of our honey comes from alsike

clover and basswood. Last fall the bees gathered a lot of honey-dew. We had to take this from them and give them syrup instead. We use the Simplicity hive.

HERB. SHIPMAN, age 13.

Cannington, Ont., Can., June 24, 1885.

ADELE'S REPORT.

I will tell you about pa's bees. He had three stands last spring, 7 in the fall, which he had to feed, except two, and did not get much honey. Now they are all dead except one. He took the black queens from three, and put in Italian swarms; but one would not stay with the black ones. One died, and one he has yet. The hive is nearly full yet.

ADELE SIEFKER, age 8.

Campbellton, Mo.

WHAT THEY HAVE GOT NEW AT LEE'S HOUSE, JUST AS HE WROTE IT.

WE HAVE GOT A LITTLE CALF AND SIX PIGS. WE ARE WELL. I AM SIX YEARS OLD.

BROOKSTON, TEX.

LEE FITZGERLED.

There, now, Lee, we have got a little new calf at our house too. It belongs to the Jersey bossy, and I tell you but it is a nice one. I told my wife, that just taking a good look into that calf's eyes, when I was tired of reading letters, was worth more to me than a doctor's prescription. But, is not our Jersey cow proud of her calf, though? You are ahead of us on pigs, Lee; but we have got four little rabbits, and, oh my! but aren't they cute and funny? They have got big enough now so that their mamma goes off a long way and leaves them to keep house all alone.

HOW TO GROW A CALADIUM ESCULENTUM.

Mother keeps bees. She has 18 colonies, all booming except two. I am writing under a shade tree and watching the bees. I will tell you how mother grows the *Caladium esculentum*. She makes a place about 2½ feet across and one foot deep, fills it up with good rich earth, and manure from the cow-yard; gives it plenty of water all the time except when it is raining. She gets her plants and bulbs from James Vick, of Rochester, N. Y. When the caladium is well supplied with water, little drops of water as clear as crystal drop from the point of the leaf. If this is of any value, please send a picture of the house apiary.

MARY F. PIERSON.

Kellerville, Ill., June 24, 1885.

To be sure, your letter is worth a book, my little friend Mary. If the plant you mention is the one that always has water dripping from its leaves, it is the plant I want just now. I have hunted over my catalogues to find out more about it, and I want one right off this season, if it is not too late. I will write to Mr. Vick to-day.

AN APIARY OF 250 HIVES.

Papa has 250 stands of bees. They are mostly Italians. I have two stands. I help work. Papa has some Holy-Land bees. I like the Italians the best. Papa has one stand of bees where he put a cell in a cage, and the cage in the hive. He forgot it, and left it there 20 days, and when he went back the queen looked as nice as any queen. He turned her loose, and the next time he went back the combs were laid full.

MINA WOLFE, age 11.

Lathrop, Cal., June 7, 1885.

Friend Mina, you have given us quite an important fact. Of course, we do not know

when the queen hatched out: but she might have been in the cell, say five days: but even then she was 15 days old when your father let her out, and I know that queens do sometimes commence to lay after they are between two and three weeks old, though ours usually lay at about ten days.

PHARES' LETTER.

My pa keeps bees. They commence working about February on the water-elm and willow. By the first of May the whole prairie for miles is covered with flowers. There is a kind of blue flower we call buffalo clover that the bees work on, and old maid, and horsemint, by the acres, all over the prairie. My brother and I go to school. I plowed this year for the first time in my life. I have a cow and a calf, and a shoat. My cow is only two years old. That is all the property that I have.

PHARES A. ROBERTS.

Brandon, Texas, June 28, 1885.

Friend Phares, do you mean that you have a flower that grows on the prairie, called "old maid"? If so, I do not think it is a very genteel name, and I would suggest that you have a better name for it. The term is a term of disrespect, a good deal out of date, and I think it would be a good thing to drop it for ever.

JOHNNIE ELBERT, HENRY AUGUSTUS, AND THE REST OF THEM.

I live on Wallace Prairie. We moved here about two years ago. We do not live far from the creek, and sometimes I go a fishing, but catch nothing but minnies, so I do not go often. My brother is taking GLEANINGS. He has 16 colonies of bees, and my sister has two colonies. I have two sisters and three big brothers and a pair of twin brothers that will be two years old Christmas day. Their names are Johnnie Elbert and Harry Augustus. Sometimes they go out where the bees are, and throw sticks at the hives and they get stung. Yesterday Johnnie E. and Henry A. were playing in the yard, and a bee stung Johnnie E. on the lip, and it was swollen so big last night that he could see out of but one eye. One day I went out where the bees were and saw both babies in the bee-house. There is a log hive with a hole in the side, and the comb was sticking out of the hive, and the babies were trying to pull the comb off, but the bees did not sting them before I got there.

I have not many flowers this year. I milk every morning but Sunday morning, and then I cook breakfast.

ROSALIE SOMERFORD, age 11.

Navasota, Texas.

LILLIAN'S LETTER.

I thought I would write you a few lines, and tell you about the bees. There is a honey-bee making a nest at the side of our door. One of grandpa Stephens' hives of bees swarmed on Sunday, and I got stung five times. The queen was killed, and the bees were awful cross. Well, I must close. If you think this letter is worth a picture, please send me one of a bird.

LILLIAN M. STEPHENS.

Blairsville, Pa., June 28, 1885.

Yes, Lillian, your letter is worth a picture; but will you excuse me for telling you and the rest of the little folks that you have two sentences in your letter that occupy space and do not tell us any thing we did not know before? The first sentence is the one

you start out with. Instead of saying you thought you would write a letter, just go on and write it, for we all know, without being told, that you must have thought of it or you never could have written it. The other is that sentence at the end, where you say, "I must close." If you had just closed without saying it, we should have known it all the same. I have crossed out such expressions in a great part of the letters that come, and should have crossed that out in your letter, had it not occurred to me to give you a word of caution about it, for your letter contains two of these sentences, as you see.

ARTIFICIAL HONEY.

Take soft water, 4 lbs.; white and brown sugar, moist, 20 lbs.; pure bees' honey, 3 lbs.; cream tartar, 80 grains, essence of roses, 24 drops. Mix the above in a brass kettle, boil over a charcoal fire five minutes, take it off, add the white of two well-beaten eggs. When almost cold, add 2 lbs. more of bees' honey. A pint of the decoction of slippery-elm bark, of the consistency of cream, will improve the honey, if it be added by cooling. The above will make 35 lbs. of pure honey, equal in every respect to bees', and at about one-third of the cost. If made for family use, only a small quantity need be made at a time. Keep it in a cool place.

JOHN ELLIS, age 10.

Armstrong, Kan., June 29, 1885.

I suppose, John, you copied your recipe out of a book, and very likely it is good, although I have never tried it. If I am correct, it is the very same recipe that our friend H. H. Lake, of Lavansville, Pa., used to sell for two dollars; and at the same time he was selling it for two dollars, it was published in Dr. Chase's recipe-book. Slippery-elm will do very well for present use; but if you try to keep it, it will induce fermentation in hot weather. John, do you mean to say it is equal in every respect to the honey made by the bees because you have tried it, and used it at home, or because the book said so out of which you copied it? Our little friends should be very careful to give credit when they copy any thing—that is, do not copy any thing from print and let it pass as your own. Among book-men and newspaper-men this kind of work is considered a pretty serious charge.

JOHN'S REPORT.

I will let you know about the bees. They can gather much honey. The linn-trees are full of blossoms, and the buckwheat is ready to get blossoms from, and there is much clover where they can get much honey. We had three swarms, and lost one. We have not taken any honey yet, but we shall some day this week. We got them double boxes, and pretty full of honey. We have two pretty good queens.

A swarm of bees in May is worth a load of hay;

A swarm in June is worth a silver spoon;

A swarm in July is not worth a fly.

JOHN J. SCHWARTZ, age 13.

Berne, Ind., June 29, 1885.

Why, John, you don't mean the linn-trees and the buckwheat are in blossom at about the same time out where you live, do you? We don't have buckwheat in bloom here until the linn is past and gone a long while.

The little verse at the end of your letter is rather behind the times. We think a swarm of bees in July is worth more than a silver spoon, and sometimes as much as half a load of hay, any way.

SAMUEL'S REPORT FROM RATTLESNAKE APIARY.

I am 12 years old, and have helped my pa with his bees for four years. I have requested my pa many times to write to you our experience with bees, but he will not write except on business. In the spring of 1881 we had 5 colonies of bees in box hives. With the help and instructions of a good neighbor (Mr. Fox) we transferred to Root Simplicity. The spring of 1882 found us in Blasted Hopes. We had but two weak colonies left, and not more than a pint of bees in each one. The year 1882 proved to be a good honey year. From early spring until November our bees were on a constant boom. We found two bee-trees, caught a swarm, bought two swarms, and went into winter quarters with 16 colonies—two weak ones.

The year 1883 was a very poor year. From 16 we increased to 34, and had some honey for home consumption. Last year, 1884, was a very poor honey year. We increased by natural swarming from 34 to 71, and got about 3000 lbs. nice comb honey in supers. In wintering we lost four colonies by carelessness; sold four for \$5.00 each; have increased this spring to 93; bees still swarming, and bringing in honey fast from horsemint.

Pa received the Novice extractor you expressed to him a few days ago. Express charges, \$3.10. Cost of extractor, \$10.20.

With your permission, Uncle Amos (if you will allow me to call you uncle), I will write again and tell the juveniles of our Rattlesnake Apiary, located eight miles west of here, in a rich prairie-valley-bottom black-land country, a natural flower-garden. Pa sends respects and many thanks.

Jones Prairie, Tex.

SAM'L H. TERRAL.

Thank you, Samuel, for writing when your papa was so busy and wouldn't. We shall be very glad to hear from Rattlesnake Apiary; but I presume some of the other children besides myself might like to know why "*Rattlesnake* apiary."—Your natural-flower garden I should think would be just the place for the bees.

THE MISHAP THAT CHARLIE'S FATHER MET IN TAKING DOWN A SWARM OF BEES.

My pa does not keep bees, but his little boy does. He has 70 colonies. He lost 25 this spring; had 45 packed in chaff; lost only one of those. Pa's boy thinks he will not get much clover honey this year, because there are hardly any blossoms. Last year he had a big lot of it. I like honey, and bees too, when they don't sting. One time there was a great big flock of them alighted away up in the top of a big apple-tree. There was as much as a painful of 'em. He got a great long ladder and stood on the top of it, and had to stretch himself away up to reach them. The limb on which they were broke, and the bees came down all over him. They crawled into his hair and stung him on the face and neck, as many as five hundred or more. Sister said you could not put the point of a pin down (may be she meant head instead of point) without hitting a sting. Any way, I guess they were about as close as they could be and be healthy. It did not swell much, but his head and neck were sore for two or

three days. I think foundation in comb honey is nice, because you can have a lot of wax to chew as gum. I think if Mr. Hutchinson were here with his honey he would have to ship it to more than *one* fair and back home before it would become soft and mellow enough for the people to buy.

CHAS. OLIVER, age 13.

Springboro, Pa., June 23, 1885.

LIZZIE'S HEN'S-NEST DIVISION-BOARD.

I see you are interested in the poultry business as well as the bee business. Well, so am I. I am partner in the poultry business with mamma, and the bees with papa. I have had a good laugh at your expense. This is where the laugh comes in: I see in your juvenile department about those two old hens on one nest. I will now tell you the way mamma and I do when two hens want to sit on the same nest. We just simply put a division-board between them, no matter if it is only high enough to keep them from mixing their eggs. I have concluded that, if you had been as well posted in the hen-sitting business as you are in the bee business, you would not have forgotten that division-board. You have heard the old saying, that two women can never agree in the same house.

Now about those nasty, dirty eggs. That poor old hen might just as well have had a nice lot of little downy chicks as not, if you had just taken a basin of warm water and washed those eggs and put some clean straw in the nest. That is the way we do. I should like to have you try these plans and report. Now about the bees.

There have been heavy losses about here, but we went into winter quarters with 12 stands of bees and honey; lost one colony, and the rest came out in good condition. We have had four new swarms this spring. Papa wants to know what you would do with two swarms in the air at once. This is what he did: He just flew or run around and got both swarms into their new home with very little trouble. He says that is thanks to clipped queens. He says when both those swarms came out it made him feel like the man who said, when his bees run away, that five dollars in the hand was forty dollars in the air.

This is my last letter before I am 15, so I should like to have that picture of your old apiary.

Pada, Ill., June 22, 1885.

LIZZIE BARNES.

Well, I declare, Lizzie, I have heard of division-boards for bee-hives, lots and lots of times; but I do not believe I ever heard before of a hen's nest with a division-board in it. Since you mention it, it seems to me the idea is just good common sense, but I never thought of it at all. Only last week two hens wanted to sit on the same nest again, and I will tell you how I fixed them. I just "swarmed" them "artificially." You see, they were both in a barrel. Well, I took one hen off the nest; then I just handed the barrel over the fence to Ernest, and set another barrel just like it in the place occupied by the old barrel. The hen that had her nest in the old barrel stuck right to it, of course, and t'other hen just walked right into the new barrel, of course.—Two or three of the juveniles have told about washing the eggs off; but, dear me! I have too little time to wash off many hens' eggs. I guess I will get Blue Eyes to boss the poultry-yard. No doubt she would beat me all to pieces.

OUR HOMES.

Whatsoever ye do, do all to the glory of God.—
I. Cor. 10: 31.

MR. ROOT:—My dealing with you, although small, is a surprise to me and to others, my neighbors. If a man can hardly trust his friends, how can he trust strangers?

It is a study to me to know whether you are by nature an honest man, or has religion made you so? or is it policy, or all? According to my experience, people belonging to the church will bear watching. You have won my confidence, any way. I believe nature made you an honest man, and I wish there were more like you. MARION BROWN.

Sebewa, Ionia Co., Mich.

No doubt many of the friends will think it a little singular that I have chosen such a letter as the above to start *Our Homes* with; and, in fact, many may think it singular that I should publish the letter at all, as it plainly was not intended for publication. I have taken the liberty to print it, however, because it so plainly strikes at the point I wish to talk about; viz., why are you honest? or, if you choose, why do you try to be honest? Why does anybody try to be honest? I thank the writer for his very kind words, and for his good opinion of us here, and his kind compliment to our business methods; and I only hope he may have charity sufficient to overlook our faults and failings, which he will be sure to find, should he continue to have dealings with us. It is quite evident that he has seen something in our business methods that attracted him and pleased him. Perhaps it is our custom of notifying all our patrons promptly and repeatedly, if need be, of any little balance there may be belonging to them on our books. It does not matter very much, any way, only I believe he is right thus far, that he has found us just as anxious to pay over any little balance remaining as we would be to get any little balance remaining that was due us; at least, I have tried for years to throw out self in all our business managements; but I know I have failed sadly many times, for I have looked back afterward and seen the effects of selfishness.

Now, then, the question, Does religion make a man more honest? or, if you choose, *ought* religion to make a man more honest? What good comes of being honest? Even the juveniles might say that honesty is the best policy. Everybody repeats this little maxim, and everybody believes it in the abstract; still very few of us believe it in practical life, else why are we not more honest than we are? Our faith is evidently a narrow and contracted faith. We mean in the abstract to be right, fair, and honest; yet at the same time self-interest warps our faith in the belief that honesty is always the best policy. Well, suppose you should be thoroughly convinced that honesty is the most profitable, would the motive be a very commendable one? A sharper proposes to be honest when he is clearly satisfied that it will be the best policy to be so; and yet nobody admires or respects a sharper. Our friend says that he believes nature made me

an honest man. I hope it is true, that God implanted in my heart a love for fairness and fair dealing; and I know, too, that my father and mother taught me carefully to be honest and true. But, granting this, have there been any struggles, any conflicts, as you might say, in my heart in regard to this matter? Was I born with such a love for honesty and fair dealing that, together with the teachings of my parents, it became easier and pleasanter for me to be honest than to be dishonest? In one sense I might say yes, and in another *no*—*emphatically no*.

Before I go any further I want to say that our friend has taken myself for an *illustration*, and there are some reasons why I prefer to use *myself* as an illustration. I know the workings of my own heart, but do not know the inner life of any other human heart. Furthermore, I do not for a minute believe that I average better than the common run of humanity. If I did, it would be a rather sad, sad world. God has implanted in the hearts of every one of us a love for truth; but without encouraging this love, without careful training, and the benefit of Christian friends, I very much doubt if any human being would be honest and true. A very bad boy might be made a good man, by careful training and teaching. I think most of you will assent to this. A good boy can also become a very wicked man, under the influence of bad surroundings. I think you will all assent to this. It follows, then, that the natural disposition has not very much to do with it; at least, I do not think it has *very* much. I have watched the matter for a great part of my life; and the more I observed, the more I felt satisfied that a human being becomes good or bad, at least very largely, under the influences of his surroundings. Plenty of money, nothing to do, evil associates, and where is the boy that will be good and true in spite of them?

I have often looked back to my childhood, as far as I can by the light of memory, to see if I could discover when bad impulses came in. When I was quite a small child I had quite a reputation for truthfulness; but for all that, I had not very much conscience. I was free from many of the vices of other children, because there was no inclination that way. I believe I always liked work, so there is no particular credit due me because I was industrious, and worked hard to earn what money I wanted. That is, I respected the rights of others pretty well until a temptation sufficiently strong came before me.

The first glaring piece of dishonesty that I can remember was when I was a juvenile, keeping poultry. A kind miller near by said if I would sweep out the mill I might have the sweepings of the floor. He evidently considered me honest, or he would not have made such a proposition. I was expected to sweep the mill all over, and so went away up in the third story, where the miller seldom came. Now, in sweeping, many times I came pretty near heaps of grain as well as heaps of ground feed, and different kinds of stuff. I was all alone; and if some of this feed were mixed up with the dust of the floor no one would know it.

I was very anxious to make my poultry venture a success. I was raking and scraping every thing to feed my "biddies." I am sorry to say that I got into a way of letting my broom brush into the edge of the feed in a way that I would not have *thought of doing* had the miller's eyes been upon me. I had got the poultry fever, and was full of enthusiasm, and I listened to the voice of the tempter under circumstances when I would not have done it otherwise. It pains me to speak of this; but the question my friend propounds some way seems to make it necessary, to bring it out. I can not remember that I was ever discovered in this little bit of theft. It amounted to only a few cents, it is true; but it was a start in dishonesty.

Not long after, I wanted to buy some corn of my father to carry my poultry through the winter. Of course, my father let me go to the corn-crib and measure it out myself. He was away from home, and I had charge of every thing, and of course no one knew what sort of measure I gave myself. Well, I got into a habit of measuring up a bigger bushel of ears of corn than I ought to have done; bigger, in fact, than they would have been had my father been around where he might have seen my heaped-up bushels. You may say this was only a small matter; that my father should have given me what corn I wanted for my poultry. Even if this were true, it was dishonest in me to take more than a *fair, just* bushel. I can remember distinctly how these experiences hurt and crippled me.

Not long after, I took my younger brother to the mill one day, that I might please him by a sight of the great wheels going around. I wanted to show him the great water-wheel; but to do so a little door had to be opened. I did not know whether I ought to open it without asking leave or not, but I took the chances. One of the hinges was broken; and when I unhooked the door it fell down so as to drag on the water-wheel. I slipped away; and when the miller came around, I either pretended or told him outright I did not touch it. You see how easily one sin follows after another. I did remember that my younger brother was a witness to my untruthfulness, and it troubled me some. At this very time I was learning verses from the Bible, in the Sunday-school. My mother talked to me over and over again in regard to the practical application of these Scripture texts. She told me that God saw, even if nobody else did. She did not know about the sweepings in the mill, nor the heaped-up bushels; but I did, and it did not take me long to connect the two. If there *was* a God—an *all-seeing* God, as she and the Bible taught—he looked on, even if the miller and my father did not. Then the question arises, Is there truly a God, and does he look down and see all these things, or is this only all a myth?

We lived in a community composed largely of infidels and skeptics. The teachings of these infidel men would be, that it was all a myth, and that I did not need to trouble or worry myself about these trifling dishonest tricks I have mentioned. My friend, where do *you* think safety lay—with my mother

and the Sunday-school, or with these men that talked "modern science" and *no* personal God? Of course I can not say positively that other children are influenced in their actions as I was by these teachings; but all along those years, and clear up through my teens, I was vacillating between the God of my fathers and the teachings of modern skepticism. At times I accepted my mother's teachings, and I used to have a little prayer to say at night before I went to sleep. The little prayer is the same one that we furnish free of charge on the little printed cards we give away. When I went through the day striving to do right, it was a pleasure to me to repeat this prayer before going to sleep. When in my zeal to make my poultry or something else prosper, I yielded to temptation, and was dishonest, I felt like skipping my little prayer, and I either said it mechanically, without either thinking or caring what the words meant, or I omitted it entirely. Sometimes for long months the prayer was dropped and forgotten; but again, when I felt bad, or got into trouble, I would go back to my little prayer, and may be stick to it for weeks or even months. If it is indeed true, that children are influenced by little things like these, how very important is it that they be watched and looked after! Can any thing atone for a parent's neglect? Fathers and mothers whose eyes are on these pages, do you not know that it is not only possible but highly probable that your boy or your girl is even now subject to temptations, such as I have mentioned? May be a little talk about God the Father, and a few Scripture texts reminding them of that all-seeing Eye, may strike just in time to save from a wrong act, and, may be, save a soul as well.

Well, I went on through life until I was about 35 years old, in much after the fashion I have narrated. Sometimes I accepted Christ as the Savior, and sometimes I did not. In using the word "accepted" I mean that I decided in my own mind that I accepted him as the Savior of the world, but did not make any public acknowledgment. During these 35 years of my life I reserved the privilege of accepting or rejecting, as circumstances might make it convenient; for if I said nothing to anybody about it, no one could call me inconsistent. Of course, I *myself* saw my own inconsistency; but as long as nobody else saw it, it was not much matter, *especially* if I decided it was all a myth any way. When I became a man, of course temptations of a different sort presented themselves; but it did not take me very long to decide, as perhaps the world at large decides—at least on general principles—that honesty is the best policy, so I always paid my debts, and as a rule kept my promises. I am ashamed to own it, but my life was in some sense like goods in the hand of an auctioneer—I was prepared to sell it to the highest bidder. If Satan had any thing in store sufficiently attractive, why, then I would accept Satan; if religion or any thing of that sort had something to present that I liked better than any of Satan's wares, why, common prudence would dictate that I should become a Christian. It was all self

and selfishness. I did not propose to give up self for anybody or any thing; nor did I propose to let go of any of my privileges. I wanted freedom—freedom to do right or freedom to do wrong; freedom to commit crime, to put it plainly, whenever it should become very much of an object for me to commit crime. You may think this is a hard way of talking. I admit it. You may say, too, "God have pity on such a specimen of a man as you used to be." I say amen to that too; and may God in his infinite mercy have pity on any who are in the toils of sin.

Now, then, dear friends, what effect did becoming a Christian have on my life? What effect *ought* a profession of Christianity to have on any man's life? Why, it had this effect on my life. I can express it better by a little text than by any words of my own, although at the time I decided to accept Christ and become a Christian. I had not noticed the text, which is this:

Thou shalt love the Lord thy God with all thy heart, and with all thy soul, and with all thy mind, and with all thy strength; and thy neighbor as thyself.

This I resolved to do before men, and I resolved to do it before God. Some of you may remember that it was while I was alone by myself—no human eye near. I just knelt down alone and told God what I had resolved to do, and asked his help, and received a promise of help there on the spot. Now, do not misunderstand me, and do not criticise me too severely, when I tell you that, from that moment to this, I have never once had a thought of turning back and rejecting God. I have met temptations, and sometimes sore ones. Sometimes I have given way to temptations, and acted in a very unchristianlike way—in a way that many would say, "A pretty specimen you are, for a Christian!" But at the time I had no deliberate purpose of letting go my religion, or of turning back from the resolution I have spoken of. Just one illustration: Sometimes when stirred up it seemed to me to be a Christian duty to give somebody a piece of my mind, and, of course, when I got started I said more and went further than I had intended to. I afterward saw my mistake, and asked God's forgiveness, and oftentimes asked forgiveness of the one I had spoken to with too much harshness. Instead of a deliberate sin it was a mistake, and God taught me to avoid such mistakes in future by resolving to wait an hour, or even twenty-four hours, if the case seemed to demand it, before administering the reproof that I knew it was my duty to administer. You see, I grew in the Christian graces, and every Christian ought to grow every year of his life.

In the above illustration you can see there was no deliberate purpose of disobeying God; but I committed a sin nevertheless, by acting hastily and without wisdom. Christians oftentimes commit sin by *dallying* with temptations. They sin because they do not turn resolutely and promptly away from evil. This is almost unavoidable because we are human. "He knoweth our frame, that we are but dust." Well, a Christian ought to learn to overcome selfishness in the same way he overcomes an evil temper—choke it

down at the outset; therefore he should improve in honesty.

Let us emphasize a little the importance of standing up before men when you decide to accept Christ. It seems to me it is not in the power of any human being to stand safe and sure without confessing Christ before men. The first thing to do is to tell God of your decision, and then straight afterward tell the world of this resolution. It does not amount to any thing unless you confess Christ publicly. The best way of doing this, as it seems to me, is to unite with any body of Christians near you. You know, Jesus told the lawyer that, after loving God with all his soul and strength, he must love his neighbor. You can not very well love your neighbor without his knowing it. God wants to be honored; and to love him with all your mind and strength, without saying a word to anybody, would be dishonoring him. It would be equivalent to being ashamed of him. Ashamed of Jesus! why, the thought is in itself awful. Now, then, after you have made this public profession you must be honest or you will straightway be branded as a hypocrite, and so you ought to be. Friend Brown says, "According to my experience, people belonging to the church will bear watching." That is right; by all means, watch Christians. Why, I love to be watched. I want you to count, measure, and weigh every thing you buy of me. I want you to find fault, and complain. I want you to say, "Mr. Root, is this Christianlike?" I want you to say, "We be brethren." I want you to quote texts, pound it into me, straighten me up, and let us all straighten each other up. If some brother in his zeal strives to get a mote out of your eye when it seems to you he has already got a beam in his own eye, take it smilingly and lovingly, for he is a brother notwithstanding. Christ died for him. Peter says:

What glory is it, if, when ye be buffeted for your faults, ye shall take it patiently? but if, when ye do well, and suffer for it, ye take it patiently, this is acceptable with God.

"Acceptable with God!" To be sure, it is. The friends have accused me of mixing religion and business. Why, the trouble is I have not mixed them half enough—that is, practical religion. As well might one object to mixing honesty with business. Did you ever hear of a man mixing too much honesty and truthfulness with his business transactions? Why, no; surely not.

Not very long ago I had a talk in regard to the expression, "For Christ's sake." Now suppose, when somebody asks you why you are honest, instead of saying, "Because honesty is the best policy," say, "I am honest for Christ's sake." One of the friends said a few months ago, that he did not give up tobacco because he wanted a smoker, nor because he thought it hurt him, but he stopped using it "for Christ's sake." How does that sound, friends? Is it not a little more worthy of sensible and rational beings, than to say, "I am honest because honesty is the best policy"? or "because I make more friends by it, save more money, win a great name, make people look and stare, and say, 'How wonderfully honest he is!'"?

Suppose you simply say, "I am honest for Christ's sake;" and after having said it, suppose you go on doing right for Christ's sake; wouldn't you feel better about it? In the 25th chapter of Matthew, you remember that Jesus tells us about the people who ministered to him when he was hungry, gave him drink, took him in when he was a stranger, clothed him, visited him when he was in prison. These people did this without thinking about the motive, but they did it for his sake; and he closes by saying, "Verily I say unto you, inasmuch as ye have done it unto one of the least of these my brethren, ye have done it unto me." We should be honest because we love our fellow-men; and as we love truth and justice, we love to see everybody have what is fairly his own. Well, in giving these fellow-travelers around us what is their own, we are giving Christ Jesus what is his own. Did you ever think of it, friends?—when we cheat a man we cheat Jesus the Savior. No matter who it is, nor how obscure, no matter how helpless, if you wrong one who can not maintain his rights, you wrong the Savior himself. His words are, "Unto one of the least of these my brethren." Jesus was the Son of man. He was born as we are born, and claims all humanity as brothers and sisters. If we wrong one of them we wrong him. If you are fair and honorable with all of them, you are fair and honorable to him, to God the Creator of the universe, he who sees with that all-seeing Eye, and who looks down upon the various trifles of our every-day lives. Why, then, should we be honest? Because we get along better, and make more money? No, no; not for such a reason, but because of love to God, and love to our fellow-men. While I go over these thoughts, my own conscience lashes me. Why have I not held better to my teachings? And again wells up that old prayer of my heart, "Lord, help! Lord, help!" Help me to glorify thy name by making all my business deal more in accordance with these Home Papers. Help me to constantly feel that it is for Christ's sake; that it is to Christ I am looking, and for the sake of Christ that I am buying and selling, and doing business. And help me, O Lord, to remember the sacredness of my position; and help me, even when I am writing these Home Papers, that they may all be written for his sake.

Now, then, what kind of help do we want? Do we want boys and girls who are working to please their employers, or who are working to please Christ? Shall a man be faithful because he thinks his employer's eyes will go over his work, or because he knows his employer's eyes are upon him? or shall he work faithfully because he feels that God's eye is upon him? What motive do we want to hold up before our children for being faithful? Shall we tell them that dishonesty is sure to be found out, sooner or later? or shall we teach them that God sees it the moment it is done? Which are best—those who work for love to God and their fellow-men, or those who work without any God about it? Friend Brown, my answer to your question would be, that making a

Christian of a man makes him honest, most assuredly; and no matter how bad a man he may be, or may have been, if you can induce him to accept Christ, and to live for Christ's sake, he is not only a saved man, but he is an honest man.

Blessed is the man that walketh not in the counsel of the ungodly, nor standeth in the way of sinners, nor sitteth in the seat of the scornful. But his delight is in the law of the Lord; and in his law doth he meditate day and night. And he shall be like a tree planted by the rivers of water, that bringeth forth his fruit in season; his leaf also shall not wither; and whatsoever he doeth shall prosper.—PSALM 1:1-3.

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

A. I. ROOT,
EDITOR AND PUBLISHER,
MEDINA, O.

TERMS: \$1.00 PER YEAR, POSTPAID.

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, JULY 15, 1885.

Thou God see't me.—GEN. 16:13.

DISCOUNT ON FOUNDATION AND SECTIONS.

TEN per cent off from list prices on fdn., as given last month, and also 5 per cent off on sections for the rest of the season.

LONG LETTERS.

At present I am unable to even read all of our correspondence; and if you write very long letters, please bear in mind that all such will probably have to be read and answered by Ernest or some of the clerks.

THE HONEY YIELD UP TO THE PRESENT DATE.

BASSWOOD is yielding bountifully with us, and many reports from different localities seem to indicate the same. Orders for honey-pails, glass receptacles, and other supplies for storage and retailing the crop, are now starting quite a brisk trade.

FINE QUALITY OF THIS SEASON'S HONEY.

As yet we have not heard a word about honey-dew this season; but all of the honey brought in to us has been of excellent quality, both in looks and taste. If it is true, that our surplus during 1885 is to be free from the honey-dew troubles of 1884, we certainly have one thing to be thankful for at least.

A PERIODICAL, AGAINST THE USE OF TOBACCO.

We have received Vol. 1, No. 1, of the *Antidote*, published by the author of the little book called "A Dose of Truth." The paper's motto is, "Ye shall know the truth, and the truth shall make you free." The subscription price is 25 cts. per year. Address the *Antidote* and *Herald of Freedom*, New Florence, Pa.

NEW BEE-JOURNALS; WANT OF COURTESY, ETC.

In my remarks in regard to the above on page 469 of our June 15 number, I did not dream of intimating that the *Canadian Bee-Journal* had been faulty in the way I suggested, but quite the contrary. If Bro. Jones has allowed any thing in his journal that might be considered uncourteous to the journals down here in the States, I had never noticed it when I wrote what I did.

DEATH FROM EATING POISONED HONEY.

SINCE the article on page 445, last issue, was printed, we have received very full and complete reports of the whole matter. Our thanks are due to the postmaster, and Mr. J. G. Postell, who lives near there, as well as the editor of the *Branchville Banner*. It is, a good deal as we expected, considerably exaggerated. In sifting the matter down, there are only three deaths—two negro children and a white boy, and it does not seem to me that the case is very clear that even they died from eating honey, although it is quite probable. We have also received a letter giving very full particulars, from Mrs. Dukes, the mother of the boy who died. He was about eleven years old. Further particulars will be given in our next issue.

THE CANADIAN BEE-JOURNAL.

BRO. JONES still continues to make one of the brightest and most wide awake go-ahead journals published anywhere in the world. In his issue for July 8, in speaking of suitable clothing for students in the apiary, he advises them to singe all the hair from their hands and wrists, as bees are always incited to sting by anything in the shape of hair or fur. I believe the idea is a good one. On another page he mentions that his students discovered they could tell when a colony was likely to send out a swarm soon, by the actions of the bees in front of the hive. Although I do not remember to have seen this subject discussed before in print, from what I have noticed I am inclined to think he is right about this also. The different behavior of the bees will be noticed from an hour to sometimes as much as half a day before the swarm issues.

THE OHIO STATE FAIR.

THE Bee-keepers' Association have an annual meeting on the fair-grounds. There is an especial reason why it is desirable we should rally round the Ohio State Fair this year, and that reason is because they have for the first time decided to run a fair without beer or other intoxicating drinks. Don't let the whisky men say it is a failure. We extract the following from the *Farm and Fireside*:

The Ohio State Fair will be held in Columbus during the week beginning August 1st, and we take this occasion to remind our Ohio readers that the State Board of Agriculture has resolved not to allow the selling on the fair-grounds of intoxicating liquors of any description, malt or alcoholic. This action of the State Board was taken in deference to what was believed to be the wish of a great majority of the agricultural community. It was taken with the earnest intention of making the State Fair a gathering to which every farmer of Ohio might take his wife and daughters, with the assurance that they should not be insulted there by ruffians beastialized by drink.

Moreover, this action was taken in the face of the fact that it would not only insure direct loss of a source of revenue which had previously been a material help in the financial management of the fair, but would also entail a considerable indirect loss by developing the factious opposition of the liquor interests of Columbus and elsewhere.

THE BEE-KEEPER'S HANDY-BOOK.

WE are in receipt of a revised and enlarged edition of the above book. It contains many engravings, and much valuable matter, and seems to be fully up to the present date. Several pages are devoted to reversible frames. Perforated zinc and drone-guards are also considered at length. Altogether, friend Alley has succeeded in giving us a very attractive and useful bee-book; but we think he makes a mistake in setting the price at \$1.50, by

mail postpaid, instead of the usual price of \$1.25 for books of about that size. The book does not contain nearly as many pages as the *A B C* or Prof. Cook's Manual; and besides, the amount of matter is very small on each page, being large type, large margin, and the matter very much spread out. A full page contains about 874 "ems," and a full page of the largest type used in the *A B C* book contains 3330 "ems." We can furnish the new edition at the above price, or the old one for an even dollar, postpaid.

FALSE STATEMENTS IN REGARD TO THE HONEY BUSINESS.

So large an amount of matter has been received in reference to this, together with clippings from newspapers, that it would almost fill an issue of *GLEANINGS*. We shall give the principal part of them next month. The greater part of them come from newspaper reporters who are in search of something sensational. As an illustration: A reporter went to visit a bee-man in Michigan, to write up the honey business. The bee-man was away from home, and the reporter found a large-sized bee-feeder in the back yard where the bees were being fed in the open air. Jumping at conclusions, and filling in so as to make it look as if a big fraud were being perpetrated, he made quite a sensational article, which is being copied everywhere. The gist of this report was, that this bee-man, who had about fifty colonies of bees, kept a shingle out in front of his house, saying, "White-clover honey for sale," while the white-clover honey is all made of glucose fed to the bees in the back yard. *Maybe* the reporter thought he had got the thing about right, but it is pretty evident that he did not care very much whether he was right or not. What he saw was nothing but the usual arrangements for feeding bees out of doors, during a dearth of honey; and there is no ground for deciding that the man was selling sugar or glucose as honey.

SOWING BUCKWHEAT.

Now is the time to put in your buckwheat, if it is not already done. We extract the following from the *American Agriculturist*:

Buckwheat is worth at least seventy-five cents a bushel for feeding, if it is properly fed. It is best ground with corn, as fine as possible, and may be fed with cut hay or straw moistened with water. The seed may be sown early in July. We have found thick seeding the best. At least one bushel per acre should be used. It pays to prepare the ground as well for this crop as for any other, but it is especially useful for the purpose of breaking up an old meadow and preparing it for reseeded. The sod will be well rotted and the soil mellowed and made ready for a fall grain crop, if this is desired, to be followed by the grass seed the next summer. No other crop except peas so well mellow the ground as buckwheat, and this is precisely the effect required in reseeded land. Besides this useful purpose, buckwheat is valuable for its grain. It will easily produce thirty or forty bushels per acre, if well managed, and a bushel of it is worth two bushels of oats of the light sort usually grown, which is largely husk. The crop, too, is put in at times and harvested at times convenient for the farmer.

With us we never get a good crop without sowing phosphate with the buckwheat, by means of an ordinary wheat-drill, with fertilizer attachment. With phosphate we have had a good yield of honey and grain, on ground that would not yield any thing, comparatively, without it. Of course, it may be sown even in our locality as late as the middle of August; but where it is put off so late there is great danger of losing the grain by frost.

FLAT-BOTTOM FOUNDATION.

THE foundation made by our friends J. Van Deusen & Sons, Sprout Brook, Montgomery Co., N. Y., has been before the people a good many years; but of late I can not remember of seeing any reports in regard to it. As we have some customers who prefer it to any other, we keep it in stock. It is perhaps the handsomest and best made foundation of any in the world; and if I am correct, the manufacturers furnish an article with a greater number of square feet per pound than any other make. The only objection is, that it takes bees longer to work it than where the bottom of the cells is made the natural shape. Has further experience demonstrated this last point to be correct? Who will tell us?

EMPLOYING WOMEN FOR CLERKS, BOOK-KEEPERS, ETC.

DID it ever occur to you, that an office where only women are employed must be a pleasant place? No smoking, no swearing, no impure talk; in fact, in our office there is not any talk of any kind, unless it pertains directly to business. Our office is a pleasant place, and I have a great many times thanked God for it—not only because the work pertaining to book-keeping and correspondence has mostly fallen into the hands of women, but because it seems to have drifted, some how or other, with very few exceptions, into the hands of Christian women—for let me tell you it is not every one, even among women, who win a place in the office and keep it. Come to think of it, our business in the different departments is mostly characterized by refinement and courtesy; and while this state of affairs is much due to the influence of the women who are all about us, and in every room, I believe it is more consequent upon the Christian spirit which I trust and believe pervades our business everywhere.

SEALED OR UNSEALED BROOD TO DETERMINE WHETHER OR NOT A QUEEN IS PRESENT.

DID it ever occur to you, that when you tried very hard *not* to make a mistake, you oftentimes make more mistakes than when you do not try so hard. Few things in bee culture have required more emphatic teaching, over and over again, than this one of having *unsealed* brood in every nucleus, when there is any danger that the colony may be queenless. The young larvae take the place of a queen, as it were, and half a pound of bees will adhere to their combs and defend themselves from robbers, providing they have even a little patch of unsealed brood, where without this they would all be demoralized, and become an easy prey to robbers or any other foe. Well, in my editorial in our last issue, p. 467, where I was so very anxious to say *unsealed* brood, by an error the editorial went out with the simple statement that *sealed* brood would answer for starting queen-cells, whereas *sealed* brood amounts to almost nothing; for the little brood that might hatch out, although it would prove a small addition to the little colony, could in no way help furnish the all-important queen. Now remember, it is *unsealed* brood, or small larvae just out of the egg, that we want when we are going to determine whether or not a pound of bees or nucleus contains a queen.

GUARANTEEING SAFE ARRIVAL ON QUEENS AND BEES.

SINCE the traffic in bees and queens has assumed such proportions, the question often comes up as to how much a guarantee covers. Sometimes a cage reaches its destination with some of the bees dead—

the others apparently all right, and the queen all right. Well, suppose the purchaser, under such circumstances, should refuse to receive the package because, according to his notion, it is not in good order. This does not very often happen, but it has happened a few times. Most people acquainted with bees would, for the sake of being human, if nothing else, take the live bees away from the dead and dying at once, and put them into a hive on some combs of food, and, of course, save the queen if possible, and then report to the shipper. Now, I should say, that unless the purchaser does take pains to save the queen, and as many of the bees as he can, he is not entitled to more than enough bees to make up the number that were dead. In regard to queens by mail, the shipper guarantees to deliver them safely at the nearest postoffice. If the purchaser leaves them several days in the post-office, he is not entitled to another queen. In case a queen is received in feeble condition, the purchaser should at once cage her on a comb containing unsealed honey, and place all in a hive of bees, so as to do all in his power to revive her. If she dies, or if she never fully recovers, he should state the case to the shipper, and the shipper should make her good, or furnish another at half price, or arrange it in some such way as would be satisfactory to both parties. If the purchaser does not take the queen from the office, and do all he can at once to save her life, I should say he is in part responsible. If he takes her out of the office, and lays her upon a shelf, or lets her lie until the next day, and she dies, he is entirely or partly responsible for her loss, depending upon circumstances. Queens, like the rest of animated creation, are liable to die at any time; and altogether the safest place for them is in a hive of bees. Therefore as soon as they are received they should, without a single hour's delay, be caged on a comb of honey and brood, and placed in the hive. If circumstances are such that you can not give this immediate attention, I do not think you ought to complain. The shipper simply agrees to deliver the queen in good order at your postoffice.

Every little while some one who is perhaps a little new in the business thinks he ought to have another queen, because his queen was lost in introducing; and he bases his claim on the fact that he followed the printed directions exactly. Whoever purchases a queen ought to be aware that introducing is always more or less risky; and the man who sells the queen can in no case expect to be responsible, unless he advertises to guarantee safe introduction as well as safe arrival. I believe only one queen-breeder has undertaken to do this as yet.

One thing more: Quite a few of the friends have a way of declaring a queen was never fertilized, because she may behave herself somewhat like infertile queens. I want to protest against this, because no man living has any right to say he can tell by a queen's looks or actions whether she is fertilized or not, especially after she has been shipped through the mails. Of course, queens might be caged up and sent off as soon as hatched, and they will live just as long this way as perhaps after they have been laying; but it will be next to impossible to introduce such a queen. The man who would send out *infertile* queens for *untested* queens, would probably pass counterfeit money if he had a chance; therefore when you are purchasing queens, be sure that the man of whom you buy them is honest.

DADANT'S FOUNDATION

is asserted by hundreds of practical and disinterested bee-keepers to be the cleanest, brightest, quickest accepted by bees, least apt to sug, most regular in color, evenest, and neatest, of any that is made.

It is kept for sale by Messrs. A. H. Newman, Chicago, Ill.; C. F. Muth, Cincinnati, O.; Jas. Heddon, Dowagiac, Mich.; Dougherty & McKee, Indianapolis, Ind.; Chas. H. Green, Berlin, Wis.; Chas. Hertel, Jr., Freeburg, Ill.; Ezra Baer, Dixon, Lee Co., Ill.; E. S. Armstrong, Jerseyville, Ill.; H. Drum, Adelphi, O.; Arthur Todd, Germantown, Philadelphia, Pa.; E. Kretzmer, Coburg, Iowa; E. F. Smith, Smyrna, N. Y.; C. T. Dale, Mortonsville, Ky.; Clark Johnson & Son, Covington, Ky.; King, Aspinwall & Co., 16 Thomas St., New York City; C. A. Graves, Birmingham, O.; M. J. Dickason, Hiawatha, Kan.; J. W. Porter, Charlottesville, Albemarle Co., Va.; E. R. Newcomb, Pleasant Valley, Dutchess Co., N. Y., and numerous other dealers.

Write for samples free, and price list of supplies, accompanied with **150 Complimentary and unsolicited testimonials**, from as many bee-keepers, in 1883. We guarantee every inch of our foundation equal to sample in every respect.

JOB LOT OF WIRE CLOTH

AT GREATLY REDUCED PRICES.

SECOND QUALITY WIRE CLOTH AT 1½ CTS. PER SQUARE FT.

SOME OF THE USES TO WHICH THIS WIRE CLOTH CAN BE APPLIED.

This wire cloth is second quality. It will answer nicely for covering the doors and windows, to keep out flies, for covering bee hives and cages for shipping bees; making sieves for sifting seeds, etc.

Number of Square Feet contained in each Roll Respectively.

Inches Wide, No. of Rolls.	Feet.
10	3.3 rolls of 75, 72 s. f.
12	2.2 rolls, 109 s. f. each.
20	3.3 rolls of 166 s. f. each.
22	4.3 rolls of 181, 1 of 169 s. f.
24	6.4 rolls of 200, 1 of 180, and 1 of 190 s. f.
26	7.2 rolls of 217, 38 of 216, 2 of 196, 1 of 156, 2 of 215, 1 of 210, and 1 of 151 s. f.
28	17.4 rolls of 233, and 2 of 231 s. f.
34	7.5 rolls of 281 s. f.
36	3.1 roll of 106 s. f.
38	28 rolls of 316, 3 of 283, 2 of 317, 1 each of 190, 632, 158, 136, and 215 s. f.
40	1.1 roll of 130 s. f.
42	1.1 roll of 245 s. f.
44	2.1 roll of 366, 1 of 318 s. f.
46	1.1 roll of 152 s. f.
48	12.1 rolls of 400, 1 of 209 s. f.

The following is first quality, and is worth 1½ cts. per square foot. It can be used for any purpose for which wire cloth is ordinarily used; and even at 1½ cts. per sq. ft. it is far below the prices usually charged at hardware and furnishing stores, as you will ascertain by making inquiry. We were able to secure this very low price by buying a quantity of over one thousand dollars' worth.

Inches Wide, No. of Rolls.	Feet.
12	42 rolls of 200 sq. ft. each; 1 each of 80, 95, 120, 168, 190, 280, 96 sq. ft.
26	6 rolls of 216 sq. ft. each; 1 each of 65, 86, 195, 195, 200, 201, 201, 204 sq. ft.
28	38 rolls of 233, 6 of 224, 3 of 219, 2 of 222 sq. ft.; 1 each of 49, 70, 116, 210, 215 sq. ft.
30	31 rolls of 230, 2 of 50 sq. ft.; 1 each of 100, 115, 117, 125, 125, 220, 225, 227, 237, 235, 250, 250, 157 sq. ft.
32	2 of 266 sq. ft.; 1 each of 88, 273, and 275 sq. ft.
34	26 rolls of 283 sq. ft. each; 1 each of 62, 113, 198 s. f.
36	21 rolls of 303 sq. ft. each; 2 of 72, 1 each of 130, 150, 240, 279, 285 sq. ft.
38	1 roll each of 200 and 316 sq. ft.
40	1 roll of 233 square feet.
42	1 roll of 350 square feet.
46	1 roll of 152 square feet.

REV. J. E. KEARNS, MORNING SUN, IOWA.

HUTCHINSON'S

ADVERTISEMENT.

We are now making a specialty of rearing fine Italian queens. All queens are bred from the purest and best of mothers, and the cells built in full colonies. We have one of A. I. Root's very best, selected, tested, imported queens, also quite a number of very superior home-bred queens from the apiary of "Cyrus Linswik." Besides this we have our own original stock which was built up from Dadant imported stock and from queens obtained from several of our best breeders. We are not trying to see how cheaply we can rear queens, but how good ones we can furnish. No queens will be sent out that would not be used in the home apiary. Single queen, \$1.00; six for \$5.00; twelve or more, 75 cts. each. Tested queens, \$2.00 each. Full colonies, \$5.00 each. Make money orders payable at Flint. Address

W. Z. HUTCHINSON,

15tfdb Rogersville, Genesee Co., Mich.

PRICES REDUCED!

Until further notice I will furnish untested Italian queens at 80c. each; 6 for \$4.50. Warranted queens, 90c. each; 6 for \$5.00. All queens bred from my choice improved stock, and the cells built in full strong colonies. Safe arrival and satisfaction always guaranteed.
J. P. MOORE,
MORGAN, PENDLETON CO., KY.

Red-Clover Queens by Return Mail.

I am now up with my orders, and can send queens by return mail. My queens are almost without an exception purely mated, and my bees worked just thick on red clover from the time it bloomed until the present.

NO. 68.

THE BOOM ON BASSWOOD, ETC.

NO two seasons seem to be exactly alike. Last year the honey harvest began early, was of short duration, but good while it lasted. No honey from basswood. This year the season opened late, the weather was cool, and the flow of honey light but steady—just right to keep breeding going in fine style, but scarcely enough to send the bees into the boxes. Last year we had off more than 1000 lbs. of honey July 1st; this year the bees had only commenced in the boxes at that date, and they had made only a nice commencement, some of them not that, when they began to swarm, and nearly every colony swarmed; and we think it was to our advantage that they did swarm; for by the time that basswood blossomed we had two colonies in fine working order where we would have had only one had they not swarmed. The bee-keeper needs to be wide awake, to *think*, to watch the season, the bees, and every thing, and plan his work accordingly. For three years we have kept our dish—our big tin cans and little tin cans right side up, ready for the shower of—basswood honey. At last it has come, is here now (July 22); the very air is loaded with the aroma from the basswood blossoms; the branches really seem to hang down as though they were loaded; the bees come in so loaded that they “drop,” and they work until it is dark and our cans are full. It is really astonishing to see how much honey the 100 queen-rearing nuclei bring in. It does *seem* as though bees that have but little brood, and plenty of combs to fill, store twice as much honey as bees with a hive full of brood to care for.

WOODEN QUEEN-EXCLUDING HONEY-BOARDS.

We are giving these a thorough trial this season, using about 50 of them. So far we have just one fault to find with them; and that is, the bees are inclined to fill up the openings with wax and propolis. It is very evident, that, after being in use a year or two, “something has got to be done” to clean out the openings. We tried cleaning one to-day with a tea-kettle of boiling water. We did it, but it required a tea-kettle full of water. Who will suggest a better way? How would it answer to fill a wash-boiler with them, pour in water, and boil them, keeping them below the surface with a weight, if necessary, until the water is cool. Our objection to the perforated zinc is its cost and lack of rigidity; but it has this in its favor—the bees are less inclined to fill the openings.

GUARANTEEING SAFE ARRIVAL.

Your editorial upon the above subject is good. In addition we would say, that when queens *do* arrive dead or weak, or the purchaser thinks he ought to have another queen, or the queen sent doesn't suit, let him state the matter calmly, coolly, fairly, and gentlemanly. The majority of customers do this; but occasionally one is found who seems to think that all the queen-breeder is after is the dollar—that he has no care whether he pleases his customers or not, and he writes one of those sarcastic, cutting, stinging letters that, to a breeder who is not only willing but anxious to please his customers, come like a blow in the face. We have received very few such letters—just enough to know how they hurt, but not so many as formerly. One reason is, that we seldom have a queen arrive dead since using the Good candy. We used to lose at least ten per cent. This year we have lost none since the season opened. We feel as though Bro. Good had never been sufficiently recompensed, either in money or

thanks, for giving this "Good" candy to the public in the way he has done.

It is no use, friend Root; we can neither write brilliantly nor instructively with this roaring in our ears. What roaring? Why, the roaring of the bees working on basswood. We must lay down the pen and go out and work among them.

8—W. Z. HUTCHINSON, 70—100.

Rogersville, Mich.

Well, friend H., I suppose we are to understand the wooden queen-excluding honey-boards work all right, with the exception of this objection you mention, of wax and propolis. I think a jet of steam would clean them quickly and nicely.—I want to second your request that customers may state their complaints calmly, coolly, fairly, and gentlemanly. Not more than an hour ago I received a letter from a man who could not introduce the queen he had received; and simply because his bees would not accept her, he jumped at the conclusion that we had sent him a queen imperfect in some way; for he said that, according to his experience, when bees rejected a queen it was because the queens were defective in some way. He wound up his letter by threatening to publish us if we did not send another one in her stead. Now, I do not want to be uncharitable on my part. May be this friend has been humbugged, and has decided the only way to make a man honest is to talk right up to him, and threaten to publish him in the papers. If it works with everybody as it works with me, it is a very poor plan.—We are glad to know that the basswood boom has gone away up to Rogersville, Mich.

MRS. CHADDOCK'S LETTER.

She tells us about Bees, Strawberries, and some other things.

WHY THE BEES THAT DIXON & DILLON SENT GOT AHEAD OF THE BEES WE SENT.

DEAR MR. ROOT:—There might be an advantage in the larger cage that Dixon & Dillon use. The cages that they sent their half-pounds in were twice as large as your half-pound cages, and fully as large as Mr. Gedye sent me the one-pound packages of German bees in. Then I suppose the Dixon & Dillon bees were caged only half a day. I think they could come to Vermont from Parrish in two hours. They were the sprightliest bees that I ever saw. It was nearly dark when we put the first lot in the hives—so dark that we had hard work to see the queen; but the bees went right to work as if they had been defrauded out of all the time spent in transit, and were going to make up for it. They were clearing out the hives. It was two of their first ones that built up so fast. Afterward he sent for three more half-pounds; and when they came, one queen was dead, and brother Phillips united the queenless ones with one of the others, making a pound of bees in that hive. Then he sent for another pound. The last lot that he sent for came a week later than the first; and the last pound, ten days later than the first.

Well, I went down this morning, and went through them. The two ½-lb. packages that I was jealous of have grown into full colonies; they have the sections on, and are "nosing" around in them.

The hive that had the one pound in is full also, and the bees have built new comb in the sections in two places, building upward some pieces as large as my hand. The last pound that came is next best, and the others are all much better than mine. None of them have put any honey in the sections, because they were not put on soon enough for the white-clover honey, and the basswood did not amount to any thing at all this year; and what honey the bees get now is from catnip, smartweed, mustard, and such small game, barely enough for their own use. They have not put an ounce of honey in my boxes in the last week. So you see some of brother Phillips' half-pounds almost equaled his whole pounds, but they had a week the start; and a week in the midst of the white-clover harvest is equal to three weeks at some other times. The bees go wild with greed, and excel themselves.

I looked at the queens in my "poor bees" to-day, and I never saw finer queens, so large and yellow. I had thought that I would let them alone, and see what they would come to; but when I looked at them to-day I felt sorry for them, and gave them lots of brood from other hives, and they will be all right after this.

When Mr. Gates was having so much trouble and worry, if he had only "said so," all would have been well. But perhaps he had not time to "say so." I think I can see it all. All the work to do, man crippled, baby sick, father sitting up till midnight, mother sitting up till morning, both of them getting up tired and sleepy, and doing every thing at once, and doing nothing as they would like to—nothing but waiting on the sick child—that is done just right. Then the other child is sick, and they go from one bed to the other, giving water and medicine, and are almost distracted, when here comes a "mad letter" from a "sassy woman" up in Illinois, and the father and mother look at each other and say, "We could not help it, could we?" I am very sorry for hurting their feelings, and I hope the children are well now.

Yes, I raise strawberries. I told in GLEANINGS how I set them out. Well, I did nothing more to them. The men cut off the sweet corn and fed it to the cows, and the plants grew. After the ground was frozen solid we carried straw, and covered the plants about two inches deep. Last year we did not have any berries to speak of; but this year we sold 36 gallons, and used and gave away 43. We had Crescent and Charles Downing, with a sprinkling of Green's Prolific. We sold them in quart boxes, at ten cents a box, or 32 cents a gallon, where they took six gallons at one house. We did not expect, when we set the plants, to have more than enough for ourselves. We set only 400; but this was a good year for strawberries, and ours were very fine. I have a plat of sod ground that was plowed the middle of June, and we hoed and pulled the weeds in it last week, large enough to set 500 plants. I want to have all that we can possibly eat. We ate three gallons a day; and if there are a few more, we can always sell them. I know families where there are half a dozen children living on farms, that do not raise a strawberry. I think it is cruel not to give children strawberries to eat. There are fifteen acres of them planted in and around the town of Vermont, Ill. They ship them to Rock Island, Peoria, and various other points. This year there was a glut in the market; and Dr. Taylor, who has 3½ acres in strawberries, gave out word that anybody

who wanted to might come to his fruit-farm and pick berries for themselves, if they would pay him fifty cents a case (a case holds six gallons) and the people flocked in for miles around—came in wagon and buggy loads from little towns eight and ten miles away. People who had never had strawberries on their tables took eighteen gallons. The "feast of strawberries" lasted three days, and the doctor told me that letting the people have them cheap saved the rest of the crop, as the vines would have been ruined if the berries had been left on, and he could not think of hiring them picked, and then throwing them away. So that was a kind of charity that blessed the giver as well as the receiver, literally.

A few words to sister Nellie Linswik, and I close.

My dear sister, bee-keeping is a business; religion is a sentiment; and whenever business and sentiment *can* go hand in hand, let them do so; but whenever business and sentiment come in conflict, then sentiment is bound to go to the wall. Now, I love to go to meeting; I like the music of the organ, and the good singing. When I shut my eyes I am wafted away off yonder, away from all the cares and turmoils of life; and then the sermon strengthens me, and the prayers lift me up; and when the meeting is over I like to shake hands with everybody, and talk a few minutes with the good old minister whom I have known for twenty years. Yes, I love it; but I never leave my bees to go to church, nor anywhere else, in swarming time, unless I have a substitute to care for them. Sometimes when I am "just aching" to go to meeting I ask some of the rest of the family to "play martyr" in my place; but if they look sour, or pout the lips, or make the least sign that I can read, I do not accept their services, but stay at home myself.

My bees *always* swarm on Sunday and on the Fourth of July. They have swarmed every Fourth of July since I have kept them. Last year was a very poor season for bees. I had only three swarms, and one of them was on the Fourth of July. Sometimes I ask Mr. Chaddock to watch the bees for me; but I tell him which hive is going to swarm, and fix the new hive all ready, put a goblet on a plate to hold the queen, and every thing. Mr. C. is not strong; and during the working season he gets completely worn out through the week, and he won't go to meeting nor anywhere on Sunday, but just rests; and if I would always leave him the bees to care for, sometimes he would not get much rest. And as I "think considerable of him," I don't want him to work too hard. The bees are mine, and I do not want him to feel bound to do any thing to them, unless he wants to. There are four of us now—Mallieonie, Irving, Mr. C., and myself, who are not afraid of bees; and as bees swarm only about three weeks every year (as a general thing), it is not so great a punishment after all for some of us to watch them. You know what the Bible says about taking things out of the ditch.

MAHALA B. CHADDOCK.

Vermont, Ill., July 25, 1885.

My good friend Mrs. C., I am afraid you are not quite orthodox, in calling religion a sentiment. Would you call your love for your child a sentiment, and put business before it? The Bible says, "Seek ye *first* the kingdom of God and his righteousness." No doubt you are right in deciding that sometimes you can serve God more fully by re-

maining at home than by going to church; but somehow it does not seem quite right where you speak of making business come before love to God; but I presume you did not mean it that way.

PERFORATED ZINC A SUCCESS.

IT RENDERS THE CLIPPING OF QUEENS' WINGS UNNECESSARY.

ON page 455 of July GLEANINGS, in your comments on friend Doolittle's article on "Clipping Queens' Wings," you state that you don't get many definite reports as to how the perforated zinc works, as to obviating the necessity of clipping the queens' wings, etc. I will herewith give you my experience the present season with the Jones guard.

I regard the perforated zinc as a very great advance forward in bee culture. I make my guards somewhat different from the Jones. I place one over each entrance, that is at all likely to swarm soon. When the swarm issues I am on hand to look after it. I wait until the swarm is all, or nearly all, out, when the queen will always be seen, promenading and worrying to get through the guard. I move the guard away carefully, all the time keeping my eyes on the queen, and pick her up by the wings. It requires a little dexterity to catch her sure every time. But out of some 20 swarms or over I have missed catching only two, and that was rather on account of a little carelessness. The queen nearly always makes from two to three efforts to take wing, when they can usually be readily caught.

Another point for which I value the zinc guard highly is, that when the queen is released into the new hive, by placing a guard over the entrance for three or four days, until she is established in her new home, you never need be uneasy about the swarm deserting the new hive; for if they should take a notion to leave, when they would find their queen was not along they would return. I find it necessary, while the guards are over the entrance of strong colonies, to remove them for a few moments about 3 o'clock in the afternoon, in order that the drones may get out.

Bees store honey from the

MAAMOTH CLOVER, AT MY HOUSE; SOME INTERESTING FACTS IN REGARD TO IT.

To-day I started toward the creek timber that lies three-fourths of a mile east of my apiary, where there is basswood in abundance; and when I got over into my 15 acres of mammoth clover that is out in full bloom, I was somewhat astonished to see the clover literally swarming with Italians.

"Oh! well, they smell it and want to get at it, and can't—eh?"

"No, sir."

That basswood forest lying just across that clover-field from the apiary, three-fourths of a mile, in full view, and just in its prime, and very rich, is the strongest argument that has yet come under my observation, that bees secure large stores from the red clover. I became so interested in the clover that I plucked off a handful of bloom and brought it along home, and made a careful study of it under a good compound microscope. I found quite a large proportion of the heads containing tubes quite *short*, and easy of access to the bees. Out in the fields I plucked a number of heads; and,

taking hold of the stem, and striking it a hard rap in my hand I could see the nectar splash right out into my hand.

D. E. BRUBAKER.

Maxwell, Story Co., Ia., July 14, 1885.

Friend B., if I understand you correctly, in your experience the perforated zinc, as furnished by D. A. Jones, restrains the *queen* as well as the drones. Am I correct?

AIDS FOR RETAILING HONEY.

SOMETHING FURTHER IN REGARD TO THE STURWOLD HONEY SHOW-CASES.

WE are happy to inform our friends, that, after considerable correspondence with show-case manufacturers, we have finally succeeded in getting a glass show-case made, expressly for showing packages of honey for retailing, like the one figured in GLEANINGS, page 11, 1884, and illustrated in the A B C book, page 63. We are pleased and surprised to find that we have found a firm who will furnish them so that we are enabled to supply our customers and bee-friends at an even \$5.00. Furthermore, the manufacturers agree to deliver them free of breakage. This latter item is one of considerable moment. That you may know better what you are going to get, we give cut below.

STURWOLD'S SHOW-CASE FOR HONEY.

If you want your name in bronze letters, similar to the way it is shown in the cut, the price will be 40 cents additional. The case is 24 feet high, and 16 inches square, outside measure, top and bottom. The sheets of glass of which it is made are 12 x 26. The case as made above is a little tall for its other dimensions, and we have got the man-

ufacturers to give us figures on one using sheets of glass 16 inches wide—the length as above, and the price will be \$1.00 more. The above case is to be set up in any grocery, drug-store, or other place of business where you wish your honey exhibited or sold. The show-cases will be shipped from Quincy, Ill.

Of late, we have been doing a nice little trade in comb honey in sections, by taking it around our town in a wagon. The sections are Simplicity size, 7 to the foot, Heddon's thickness, used without separators. We have sold hundreds of them, and they are sufficiently regular so they go into our pasteboard boxes without any trouble. The pasteboard boxes are like this. For prices, see cover to our issue of June 15. Of course, these sections do not hold a pound of honey.

Before the wagon starts out in the morning, one of our girls weighs the section, slips it into the pasteboard box case, and marks on the cover the price. We get 18 cts. per pound for the honey, case included, and they weigh so as to generally bring the price at about 16 or 17 cents. We have a new light spring wagon, lettered on one side, "Home of the Honey-Bees." Three hands are needed to work to advantage. Two of them may be active boys. One drives while the other two take each one a side of the street, calling at every house, and slipping out a section of honey to show how nice it is. They sell at almost every house. Even though honey is retailed at the groceries at 15 cents per lb., we find little trouble in getting 18 for these small neat packages. We propose to sell extracted honey in the same way; but just now it does not seem to take as well as the nice comb honey. One reason for trying this experiment was to see how much honey could be sold in this way; and it is my opinion that tons and tons can be sold by going to villages, towns, and cities.

A FOUL SCANDAL IN REGARD TO OUR INDUSTRY.

ACCUSING BEE-KEEPERS OF FEEDING GLUCOSE, AND LABELING THE PRODUCT "WHITE COMB HONEY."

THE following statement has been sent us by our subscribers, north, south, east, and west, and seems to have been copied by hundreds of papers, and probably will continue to be copied. We give place to it in order that we may better show the utter untruthfulness of the whole fabrication.

MACHINE HONEY; HOW A SHARP MICHIGAN APIARIST HAS EDUCATED HIS BEES.

A Wayne County farmer, says the Detroit Free Press, has succeeded in earning a place in history along with the Connecticut man who invented wooden nutmegs. He lives between Detroit and Dearborn, on Michigan Avenue, in a vine-covered cottage a little way back from the road. On the front fence appears the sign, "White-Clover Honey." Back of the house is an apiary with all the modern inventions for the care of bees, and nearly fifty hives sound with the cheerful humming of the busy honey-makers.

A representative of the *Free Press*, quite by accident, called at the house yesterday and found no one at home; and while sitting by an old well-curb refreshing himself with cool water from an old oaken bucket, his attention was called to the action of the bees. The cottage is surrounded with luxuriant roses in full bloom, but these bees did not, as bees used to do,

Gather honey all the day
From every opening flower.

Instead they were swarming around a tray which stood near by, and were flying back and forth to the hives. In this tray was half an inch of a sticky mass that looked like syrup. Little sticks were strewn over this substance, and on these the bees were alighting; and after taking some of the syrup they flew back to the hives.

"What do you want o' them bees?"

The intruder started up, and found a barefooted lad standing before him.

"What is this the bees are taking?" asked the visitor.

"What do you want to know for? Dad said we wasn't to tell any one any thing about it."

"I'll give you a quarter if you will," said the reporter, now thoroughly interested.

"Well, I donno what it is. Dad gets it from town in a bar'l. Here's what he gets it in," pointing to a large cask.

On the end of the barrel was the stencil mark: "200 lbs. grape sugar from Michigan Grape-Sugar Manufactory."

"Is that glucose that the bees are getting?"

"It's something that dad gets out of that bar'l, that's all I know about it."

The inquiring visitor tasted it. There was an unmistakable gundrop flavor to it.

"We had hard work to get the bees used to it. Dad put in a lot of syrup at first, but the bees take it straight now."

"How long does it take to fill a hive?"

"Not near so long as it does when they have to get the honey from flowers. We've taken out a lot this year already."

The boy brought out of the house a box of glucose honey which looked as clear and inviting as though the sweets had been distilled from the purest flowers.

"Do you eat it?" the boy was asked.

"Sometimes. It ain't so good as the other, but it's just as good to sell. Say, don't you ever give me away to dad, or he'd skin me."

Now, the principal point is to find out the foundation of this whole story. Doubtless some bee-keeper living near the point indicated may be able to find out how much the reporter found to build up his story on; and as we stated in regard to the honey-poisoning case, I will willingly pay any bee-keeper, or any one interested, for giving us the full facts in the case. No doubt the reporter found a man with nearly fifty hives, as he mentions, and called at a time when he was feeding his bees, perhaps for stimulating brood-rearing in the spring. No doubt he also saw the sign on the front fence, "White - Clover Honey." But that this white-clover honey was made out of glucose, we think we can prove beyond question was a mistake or a fabrication. It is quite likely our bee-keeping friend did use grape sugar to feed his bees with. But if he tried to get the bees to store the product in the combs, it certainly took longer, and cost more, than to get the genuine clover honey in the usual way. If the boy made that statement, that it did not take nearly as long as when they have to get the honey from the flowers, he was mistaken. The description of the feeder shows that it was nothing but an arrangement for feeding, as before mentioned; for such a feeder in the open air, among nearly fifty hives, would by no means enable any one of the fifty hives to store honey in the boxes. The grape sugar would also candy

in the combs as fast as the bees stored it, as every one knows who has used it for feeding—that is, if it were not used for brood-rearing; and grape sugar stored in the comb would not be salable under any circumstances. He says the barrel was labeled "Grape Sugar;" yet the *Detroit Free Press* says the man was "feeding glucose," etc. Now, grape sugar is not glucose; and feeding grape sugar can not be the means of getting glucose into the combs. I wonder how many times I shall have to go over this matter. Glucose fed to bees, and stored in combs, would have the appearance of honey, but the honey would taste more like a solution of gum than like genuine honey. I have never made any experiments in feeding glucose to bees, but I have fed grape sugar during warm weather, just enough to keep up brood-rearing, by the hundreds of pounds, and I am perfectly at home in what I am saying, when I state that it can by no means produce any thing even resembling honey—much less white-clover honey. Another thing, the best arrangement known for feeding will not enable the bees to store a fourth part as much grape-sugar syrup, or even syrup of granulated cane sugar, as is needed to make it profitable. This subject has all been thoroughly gone over in our bee-journals in years past. The whole matter from beginning to end is an utter impossibility—that is, so far as the story of making marketable comb honey in this way is concerned. If the *Detroit Free Press* think they can substantiate their statements, we challenge them to furnish the proof; and when we prove conclusively that their reporter's statement is a vile slander on bee-keepers as a class, we hope they will have the fairness to correct what they have said.

JOTTINGS FROM STREETSVILLE APIARY, ONTARIO.

A REPORT OF THE HONEY SEASON IN CANADA.

WELL, the honey season of 1885 will soon be as a tale that is told; and I very much fear that the narrator, if a raiser of that precious nectar, will not wear an "overly satisfied countenance." Clover, although abundant, has had much of the nectar washed away by ever-recurring rains just about the time bees began to gather from it. I doubt if there has been any more than eight days of full gathering yet. Basswood, although loaded with blossoms, does not now secrete honey as freely as, in days gone by, when the forest stood in large unbroken blocks; and indications seem to point that it is not now an altogether certain source of honey.

Swarming, that great bugbear of a large apiary, has been excessive; and I fear, where stocks are left unexamined by the go-as-you-please bee-keeper, many will be left in an unfit condition to face winter's storms. This class would do well to take timely warning and examine hives without delay, to see that they have either laying queens or larvae from which the bees may raise them.

I have used several different makes of foundation, but find the bees much prefer the "Given" for brooding purposes.

After a trial of queens as nature endowed them with wings, during the swarming outburst of this season, I am about satisfied there is a better way for large apiaries, and shall henceforth resort to clipping. By curtailing her majesty's ancient privilege of flight we are quite as likely to save herself, and we certainly save time, trouble, and the bees belonging to the swarm. Of the many occasions that try that most patient of men, the apiarist, one I have found to be when three or more swarms issue simultaneously, and alight on the leafy pendant limb of an elm, forty feet from *terra firma*, the thermometer meanwhile registering 90° in the shade. Then is the time to wish for a dozen of the invalid old gentlemen and delicate ladies who are so often advised (in the cool retreat of the editor's sanctum, perhaps) to try bee-keeping as an easy pursuit, requiring no particular work, no capital, little brains, not much of any thing, you know, as bees ask "no wages and board themselves."

As to hives, we are, I am persuaded, on the eve of some very great improvements—notably the adoption of the reversible frame, and cases of sections; and subsidiary to this, a practice I am now trying with satisfaction so far (not original). I refer to contracting the brood-nest of the hive by withdrawing all frames but five or six, substituting cases or division-boards twenty days after swarming, and also living the swarm on the same number of frames of fdn.; then put on section cases, and the bees will proceed to work.

In conclusion I would advise those having honey to sell in Canada, not to let it go at the bottom prices of last year. All we are now likely to raise will be inquired after before honey comes again.

J. C. THOM.

Streetsville, Ont., Can., July 23, 1885.

QUEEN-EXCLUDERS AND HONEY-EXTRACTORS.

USING THE QUEEN-EXCLUDING HONEY-BOARD UNDER A BOTTOMLESS HIVE.

AGAIN we have put to test quite a number of queen-excluding honey-boards. I now feel quite confident that they are a practical success. I know that some of my brother beekeepers will say that they knew that before. Well, I did not; and it took me two years to find it out. Many claim that entrance-guards and queen and drone traps are also practical; but I think they are not. Again this year we have tested them also, and we are of the opinion that they are not to come into general use. Where we deem it necessary to prevent the flight of drones temporarily, or till they can be let out and left out, we have succeeded by placing a queen-excluding honey-board under a bottomless hive, the entrance being under the honey-board (all our honey-boards contain a bee-space in one side). We like metal better than wood for these excluders, only because we find that such narrow passages through a sheet as thick as wood will be so clogged up with wax that most of the passage-way will soon be filled. With the thin metal, the passages remain open. But here comes the difficulty—cost. Can't we cut a corner somewhere, and get these metal queen-excluders cheaper? How much cheaper is galvanized iron, and will that do? I have the Jones size of passages, and also yours, Mr. Editor; and through either of them the

bees apparently store as readily as though it were not there. I am, however, in favor of having the passages as large as we can, and yet exclude queens. Now, what are the reports regarding this point? As far as the production of comb honey is concerned, in my practice with the sink honey-board I can see almost no advantage to be gained by the use of the queen excluders; but for extracted honey I want them. I have also discovered that two queens can be kept in the hive, one on each side of the excluder. In fact, wherever I have used the excluder, as soon as I put eggs and young larvae above it (where the queen could not go), queen-cells were started in quantity. In several instances last season, young queens were hatched. In two such, where we had put the queen above (to test the excluding powers of the board) she remained above, and a young queen was reared, hatched, and fertilized, below. This point is going to be of value to us in future. I think it is one of the valuable features of the honey-board. Is it Mr. D. A. Jones whom we owe for this invention? Let us not be guilty of omitting to give credit to whom it justly belongs.

Who will give the specialist a

HONEY-EXTRACTOR?

I know we have some very good cheap extractors on the market—some that perhaps pay a greater dividend on their cost, to the small apiarist, than would a better and higher-priced machine; but the specialist can not afford to squeeze along from year to year with such machines. Now just think of a shirt-knitting machine. If it were made as carelessly as our extractors, would it take *one* stitch? Of course, not. Once make a machine accurate and good enough, and it can be made to reverse its combs without touching them; never wriggle around when running with one comb; and by all means it should have a slip-gearing so that, when once started, it will run independently of the crank, and whirl out the honey from one side of each comb while the operator is uncapping the next. It must have a foot-brake that will stop it almost instantly, and be made durable, and be attached firmly to the building containing it. Who can give us such a machine?

For your next issue I will give you my method of "modern transferring," which we like so well, and which you call for on page 484. JAMES HEDDON.

Dowagiac, Mich.

Friend H., your plan of using the queen-excluder is, so far as I know, new. I never heard or thought of it before, and I think the suggestion does you credit. Galvanized iron is no cheaper, all things considered, than the zinc, and it is so much harder to perforate that much more expensive machinery would be required. Thanks, also, for your report in regard to the two kinds of perforated zinc.—The matter of raising queens in the same hive where a laying queen presides is quite an item. But, how would a young queen get out to be fertilized, unless she passed through the domain of the old one? From what you say, I presume she would be treated as a daughter, or an assistant, if you choose, in the egg-laying business.—Such an extractor as you mention, it seems to me, would be almost too complicated for practical work. We have made some experiments in regard to a "brake," but we gave it up.

A GOOD MANY THINGS ABOUT BEE CULTURE.

Friend Salisbury's Ideas in Regard to Them.

ESPECIALLY HIS OBJECTIONS TO CERTAIN THINGS.

I SEE frequent memoranda in published correspondence of GLEANINGS about how a bee-paper *ought* to be conducted. With reference to all such, I feel as the preacher did when taken to task by one of his congregation about the uninterestingness of his sermons. "Just step into the pulpit to-morrow, and preach yourself." Let one of these advisers start a bee-paper, and see how long he would last. I fancy he would tell *all he knows* about bees in just about *two papers*. I have kept bees over forty years; have read GLEANINGS ever since I first heard of its existence, and my last subscription, now well nigh up, was for five years. I take two daily newspapers, over half a dozen weeklies, and several monthly papers or magazines, and I look for no paper with more interest than GLEANINGS—not that I read all or even half that is therein printed, for I care nothing for the A B C letters or suggestions. I find enough, however, to interest me for an hour or two, and would not wish to be without it. What does not interest me I do not read, just the same as with other papers; neither would I dictate to the editor, who evidently knows his own business, as his increasing subscription-list abundantly proves.

WINTERING WITHOUT LOSS.

It amuses me to see individuals boast of wintering their bees without loss. I know they are either novices or have but few colonies, and by the merest accident called "luck" have got through the winter with all their colonies. One person with one thousand sheep can as well calculate on wintering every sheep as another person with one hundred colonies of bees can calculate on wintering and springing them all without loss. The only question is the per cent. During 40 years, the last 25 of which have been with movable frames, I have seldom got through with both winter and spring without some loss. Sometimes it might be, however, by the uniting of a queenless colony with a small one with a queen. I have sometimes had my strongest colony perish, with plenty, of honey and ample protection. This last winter and spring reduced the number of my colonies by one-fourth. I went into winter quarters with over 100, and into spring bloom with less than 80.

WHAT I OBJECT TO.

Chaff hives, immovable bottom-boards, wire frames, metal corners, reversible frames, fancy honey-boards, moth-traps, drone-traps, and clipped queens, and all kinds of contrivances for preventing swarming, or "catching" swarms.

CHAFF HIVES.

I object to chaff hives on account of their cost. I winter my bees as safely, and with as little loss in Simplicity hives, as in them. I remove the combs or boxes from the upper story, and fill it with dry leaves, see that the colony has from 20 to 25 lbs. of good honey in the brood-chamber, and I would wager swarm against swarm in favor of Simplicity.

PERMANENT BOTTOM-BOARDS.

I object to immovable bottom-boards on account of the difficulty in ascertaining the condition of the colony when packed for winter, without disturbing

the packing. By raising the hive from the bottom-board any mild day I can at a glance tell if any thing is wrong. Is there a mouse among the leaves, or any thing wrong with combs or bees, I see at a glance. Sometimes an unusual number of dead bees appear on the bottom-board. I brush them off and remove the cover, and work my hand down through the leaves to the cloth covering the frames. If the cloth is warm, the bees are yet sound. If cold, all the bees are dead, and you can remove or leave the hive as you please. Another thing: Bees sometimes cluster in heaps around the entrance of the hives or on its sides. People usually say those bees are preparing to swarm. I say, the inside of the hive is too warm; and if they did not come out, their combs would melt down. Raise the brood chamber from the bottom-board $\frac{1}{4}$ inch by the insertion of blocks of that thickness under the corners of the hive, and every bee will go into the hive or field in less than an hour. Never can fifty bees be seen around the entrance or sides of a single hive in my apiary, and have not been seen half an hour at a time in ten years.

WIRED FRAMES.

I object to wired frames on account of the wires. They are no good except the first year, and not much good then, unless you wish to ship them. Let the bees build out the foundation so as to rest on bottom of frame, and the wire is a nuisance whenever one desires to remove the comb from the frame. Their expense and uselessness condemn them, and the same of metal corners. Besides, let an ordinary bee-keeper with his metal corners and metal rabbets to rest on have his fancy hive overturned by some frightened animal, and the queen, with a large number of bees, are gone sure.

REVERSIBLE FRAMES.

Early this season these seemed worthy of trial on account of respectability of recommendation, especially as some frames had a bee-space between comb and bottom-bar. These are the ones I reversed, and in no instance have the bees yet filled up said space with comb. A good queen will occupy all the brood-chamber with brood during her rearing time, and bees have no difficulty in finding the boxes or super-frames in second story.

FANCY HONEY-BOARDS, ETC.

I don't consider it worth while to even say why I object to the fancy honey-boards, moth or drone traps. I object to clipping wings of the queens, first on account of cruelty to animals. Second, it is very troublesome, and frequently fails, without corresponding advantages. About fifteen years ago I Italianized my bees and clipped my queens. I was necessitated to keep all grass from near the front of the hives, nearly spoiling my lawn in order to make sure of the maimed ladies when they ventured forth. I secured a few all right—nice thing—"big Injun." Another swarm issued; I looked and looked and looked to see the queen hopping along, but no queen appeared. I opened the hive, not a single queen-cell to be found. I divided the frames, forming two hives, and filling one out with frames of fdn.; repaired to tree where bees had clustered, severed the limb, and brought them triumphantly back to their hive. They went to work beautifully; and in a few days, on examination I found a beautiful young queen acting as mistress. On another occasion I found my clipped queen balled at the entrance of another hive, a long distance from the one she had left. This closed my clipped-queen

business, and I never have even thought of trying it again. Old queens will die, and young ones will appear, no matter how closely watched, unless, indeed, you handle them oftener than once a week, and life is too short for me to think of handling them oftener than necessary. Bees always alight. I have no doubt about it; they never go off without clustering. Hundreds of swarms have I hived without losing a single one that I saw issue. These fancy things for catching swarms are of no possible account. I have hived fourteen before dinner, with only a single pair uniting, and those I could easily have separated if I had desired.

TELEPHONES.

Two or three years since I received, with other articles sent me by you, a cheap 75-cent telephone. I erected it between my house and honey-house so that the good wife could easily call me to dinner. I thought I filled all directions about its proper erection, but I could hear her call outside of the telephone, and nary a sound distinctly through it; so, down it came, and went among other useless relics of curiosity. GLEANINGS mentioned within the past year its use in bee swarming, so out it came again, one mouth-piece near my table in second story of honey-house where I keep papers and something of a library, while the other was in lower story near the extracting-table, and the wire was made to pass, say, ten feet high above second row of bee-hives down nearly to the end of my apiary, then over the second row across the end to the third row on opposite side, and around over that to honey-house. It works to a charm. I can always tell when a swarm is in the air. Of course, when young bees are taking the first flight the wire gets touched occasionally; but when the touches come like an alarm-bell I can go down, "for they've got there."

SEASON.

This has not been a good honey season thus far, With abundance of white clover and lindens now well in bloom, the cold rains and cool days of nearly the entire month of June have decidedly hindered and impeded the work of the little insects. Bees have not had the swarming fever, only 27 having issued naturally, increasing my number of colonies by 21. Two small swarms I always unite, and the colony casting a second swarm is sure to receive the next swarm that appears. I used to return second swarms to the parent colony, but found they would swarm again, whereas a strange swarm would always remain and give such strength and vigor to the exhausted colony as to insure a fair yield of surplus nectar. I find no difficulty in uniting colonies during the honey and swarming season; and as to the queens, I trust to the principle of "survival of the fittest."

BEE CONGRESS.

I expected to see something more extended in GLEANINGS in reference to the convention at New Orleans. Probably no other body of bee-keepers of equal or superior number, or of equal reputation and intelligence, was ever assembled. The proceedings were conducted in good taste, and must result beneficially.

S. W. SALISBURY.

Kansas City, Mo.

Friend S., there is a good moral to your article; and one commences to see the moral when you start out by condemning so many things. All of us bee-keepers get notions—myself among the rest. We get a notion that a thing is good for nothing, and hastily

throw it aside, just as you did that telephone, because you did not put it up the first time according to directions, or try it till you *made* it work. And on the other hand, sometimes we get hold of a thing that is hardly practicable, and not profitable, and we take a notion to it, so we stick to it until we make it do very fairly; whereas we could have done much better had we thrown it away in the first place. The friends who have some patented notion of their own are an illustration of this. Now, the golden mean would be to look fairly on all sides, and judge impartially. So long as we are human, however, I presume we shall go through life with more or less of these notions sticking to us.

Briefly, it seems to me you have got a notion that chaff hives are of no benefit; and possibly they will not pay so far south as you are. You have a notion, too, that you want the bottoms of your hives movable, while a great many of the brethren will declare that they never want another movable bottom around; and the same with wired frames. We have decided, over and over, that we want no frame in the apiary that is not built on wires. But our business is shipping bees, principally, so we may both be right. It seems to me that if we are going to have a movable frame the best way is to have it movable and removable; but a great many do not agree with me. They find the movable corners *too* movable, and upon inquiry they are accustomed to moving their hives around here and there. We have our hives located as shown in the A B C book, and I might almost say we never move them unless a colony has to be shipped. In that case, of course, we use the spacing-boards. Neither do we have our hives overturned by frightened animals. We never had such an occurrence in our experience, that I recollect. We expect our hives to have a good solid standing-place, and we expect them to stand there, winter and summer. I am astonished at what you say in regard to reversible frames; for it seems to me I could make the bees build those combs up against the bottom-bar by reversing the frame, in 24 or 48 hours, during a flow of honey, without a possibility of mistake.—In regard to fancy honey-boards and moth or drone traps, I should partly agree with you, unless you mean to include the Jones entrance-guard. The latter is a valuable thing to have in an apiary, without question.—Our notions happen to be much alike in regard to clipping queens' wings; but a good many others will have different notions, as you notice.—Now, friend S., in regard to bees *always* alighting, that sentence caps the climax in helping us to decide that you are greatly given to notions. Have you forgotten the perfect hailstorm of facts rained upon the head of poor "Old Foggy" a year or two ago, and the way in which we made him come out of his cover and own up and take back his words?—I am glad you have learned to manage the telephone.—In regard to the bee-keepers' congress, I believe you are right about it; and the reason why I did not have something extended in GLEANINGS in regard to the matter was, that there was so much of it I gave up and advised all to send to friend Newman for a copy of the

A. B. J. containing his very full report of the proceedings. I had my eyes and ears open all the time I was able to be with you, and I hope the accumulated wisdom stored up during those few hours will be cropping out here and there on the pages of GLEANINGS.

THE HONEY-POISONING CASE.

SOMETHING DIRECTLY FROM THE PARTIES CONCERNED.

FRIEND ROOT:—As I suppose I am the only subscriber you have near Branchville, I resolved myself into a "committee of one," and resolved to sift the Branchville honey case. I heard of it at the time, and believe, and so does every one here, that the honey they ate killed those people. That it was gelsemium, I am inclined to doubt; for, if this were the case, why have not others been poisoned by it before? Yellow jessamine blooms in very great profusion here. In our swamps it covers the ground and many of the tallest trees, and the bees work on it as long as it lasts. The honey that my bees made when working on it was white, clear, and as beautiful as any I ever saw, and it tasted better than any other made this year. Our April, May, and June honey is generally dark, but of good flavor. In the fall, that gathered is generally very bitter, and can not be used at all. Next spring I will take some of this jessamine honey and send it to you; and if you desire, you can have it analyzed. I can send you some bitter honey in the fall, also, if you wish.

The yellow jessamine blooms here in great profusion in the earlier spring, say January and February, and sometimes as early as December. Last spring was very backward, and it bloomed in February and March. My bees worked on it in a perfect rush, and made, I suppose, considerable honey from it, as they brought it in, and I could find very few other flowers. I took some comb honey in April that was not all sealed, and ate it, as did my family also, with no bad results. Others about me keep bees, and have done so for years, and this is the first case of the kind that I have ever heard of here. You know more of the nature of honey than I do. Now, is it possible that this jessamine honey is poisonous until purified by the bees, and sealed?

—JERU G. POSTELL.

Orangeburg, S. C., July 7, 1885.

Many thanks, friend P., for your kind services in this matter; and as I said before, if you are out of pocket in hunting up the case for us, send in your bill, and we will pay it.

The following is an account of the matter, from Mr. and Mrs. Dukes, parents of one of the victims:

We certify that we obtained some honey, a portion taken at the robbing of four gums; we also had some other honey, obtained from a different source. Two separate vessels contained the different honey. The family had been eating of the last-mentioned honey for several days, and no bad effect resulted. On the evening of the 25th of May our son Abram, about eleven years of age, ate of the first-mentioned honey, or that which came from the four gums, and had not yet been used by the family. It is supposed that in one hour, or thereabout, the honey began to affect him, producing giddiness, and he said he could not walk without staggering, and said

he was blind. He complained only of general lassitude and slight nausea, in addition to the first symptoms, and within the space of two hours a convulsion came on, and he breathed his last. A couple of days after this, some of the honey of which Abram had eaten was given to a negro woman, who gave it to some children for supper. In the space of one hour two of these children were dead. They complained of this same blindness and dizziness that Abram did, and of nausea, and some pain in the stomach. Two of the negroes vomited, and recovered. Mrs. Dukes ate some of this honey while getting it for the negro woman, and was affected in the manner described above. The report as contained in the *Banner* of June 4 is correct and true in every particular. One of the family of whom the honey was obtained was affected in a similar manner, but vomited, and was relieved without any further evil effects.

JACOB T. DUKES.

MAGGIE V. DUKES.

Branchville, S. C., July 12, 1885.

Many thanks are due you also, my good friends, for your kind services in the matter. May God be with you in your affliction. The report alluded to in the *Banner* contains nothing further than we have already given, except the following clause:

We have often heard it affirmed that in eating honey unsealed, or that robbed too early in the season, there was danger of poison. In the low country a greater portion of the honey is found to contain poison, owing, perhaps, to the abundance and variety of wild flowers in that vicinity. We have often known persons to be made slightly sick from eating new honey, but these cases of deaths above are the first ever known in this section.

I think the writer is correct in his opinion as above, that the honey that would be disagreeable or deleterious, if eaten as soon as gathered, is many times made pleasant as well as harmless by being allowed to ripen in the hives. It is well known, that the honey obtained from onion-blossoms is not fit to eat when first gathered, or when taken from unsealed comb; but if allowed to remain in the hive until thoroughly ripened, the onion flavor will be found to have passed away—or, at least, sufficiently so that it is found not objectionable. Now, another point comes up: From what Mr. P. says, it seems quite unlikely that this honey came from the jessamine at all; and as all the poison honey that we have any knowledge of came from that single log gum, may it not be that the bees by accident gathered some kind of poison prepared to kill insects? As an illustration: It would not be very strange to find honey-dew on potato-tops at certain seasons of the year. Now, if Paris green were sprinkled on these potatoes, and the bees should gather the sweet, we should have honey that would produce, may be, symptoms similar to the above. Can any of our medical friends suggest what the poison probably was, from the nature of the symptoms given? On page 182 of the A B C book, we have a well-authenticated case of poison honey from the mountain laurel. May it not possibly be that the mountain laurel is also found near Branchville, S. C.? Can friend P. enlighten us on this point? You will note, by comparing the description in the A B C, that the symptoms were quite similar.

It is interesting to note, in this connec-

tion, that, 400 years B. C., we have an interesting case of honey-poisoning, as mentioned by Xenophon in his *Anabasis*. The honey mentioned produced a violent form of diarrhoea, and it was only through strenuous efforts of Xenophon that numbers of his soldiers did not die from the effects of the honey.

INTRODUCING VIRGIN QUEENS.

SOME VALUABLE SUGGESTIONS FROM FRIEND DOOLITTLE.

BY request of several I will give the readers of *GLEANINGS* all I know regarding the introducing of virgin queens to nuclei or full stocks, hoping that, by so doing, others may be drawn out until a plan which may prove successful in the hands of all shall be brought to light. Friends Root and Hutchinson tell us that all they do is to let the virgin queens run in, as soon as a laying queen is taken out; but from the letters I receive, and the scores of queens I have lost, I judge that not one out of a hundred can do it successfully.

A few years ago, when I had a lot of 25 very choice queen-cells (which had been sealed about three days), a colony cast an after-swarm; and by my trying to save one of the virgin queens which was with the swarm, she got away and went into the colony where these cells were. The result was, that in less than 24 hours the whole 25 cells were destroyed. Here was a case of a virgin queen introducing herself without any ceremony; and after a trial of several years I find that any colony that has been queenless long enough to have queen-cells sealed and one which does not desire to swarm, will accept of a virgin queen every time; but if given before the cells are sealed, she will be destroyed in nineteen cases out of twenty, unless some precaution is taken more than to let her run in at the entrance or at the top of the hive. As Mrs. Harrison says, "As soon as the queen-cells are sealed, the bees seem to be expecting a queen at any moment, and so accept a virgin queen; while before the cells are sealed they think the queen must be an intruder."

After carefully observing the above I concluded time could be gained by caging a virgin queen two or three days old in the queenless colony or nucleus, leaving her there four or five days until the cells were sealed, when she was liberated, and so far I have rarely failed to get her introduced successfully, and to laying in a little more than one-half of the time required by the cell plan. Again, this has some other advantages over the cell plan; for in this case we can know whether our queen can fly or not, for it often happens that queens have defective wings, myself and others having such queens in hives for a long time, they defeating every attempt we made at getting a laying queen into the colony.

The present season I have been trying a new plan, which is, mixing the bees from several colonies in the wire-cloth box I use in forming nuclei, as given in a former number of *GLEANINGS*. As soon as the bees are in the box, put in the virgin queen while all are yet strangers to each other, and she will be accepted. Let the box stand a few hours in some cool dark place, when they are to be hived on a frame having a little brood, and one of honey; for

to work well a nucleus should have at least two frames. If a queen five or six days old is used, the nucleus will have a laying queen in a few days more, and the first queen from that nucleus is soon ready to be shipped.

Well, so far I am all right; but what I want, and what all raisers of queens wish, is a plan by which a virgin queen five or more days old can be introduced to a nucleus already formed, or to any colony, and have her laying in five days more without danger of having her killed. We have just disposed of a laying queen from our nuclei, and we go and shake one-third of the bees out of each of three into one cage, so as to form one as at first. Put in the virgin queen, and have her accepted. The other two thirds are put in two other cages, so we have three virgin queens introduced, and the bees to put back into our three nuclei again. All works well till I come to put them back into the three hives again, when, during the first twelve hours, five out of six will be killed. This seems to come about by there being bees left in each nucleus, some of which were in the field when the rest of the bees were taken out, and the rest remained sticking to the hive, or flew out when shaking from the combs down through the tunnel. This part of it I do not see how to overcome; and after experimenting and losing many virgin queens, I feel like going back to the cell (or caging virgin queens) plan.

Who will solve the matter for us, so it will be successful every time? If those of us who get a good crop of honey generally are to raise queens for \$1.00 each, we must have a less expensive plan of rearing them than any heretofore given, or we can not make it pay equal to honey, and might as well quit first as last, giving the trade over to those who do not get the honey. This I might so far profitably do; but when I get so many letters saying, "I hereby inclose — for queens of your own raising; remember, I want no others," I dislike to do ought else than to accommodate, and will try to do so, if I can get any plan by which I can raise queens and make it as profitable as raising honey.

Borodino, N. Y.

G. M. DOOLITTLE.

Friend D., the matter you bring up is a very important one indeed; for queen-rearing has advanced quite a step when we are able to take a queen out of a nucleus and put a virgin queen in her place, so old that she may take her wedding-flight, say, the day after she is introduced. The matter was up several years ago, and we succeeded in doing it a part of the time, but it required pretty close care, and a good many mishaps came in. The plan we used was by having a frame of cages for the cells, something similar to the invention of Dr. Jewell Davis, and since adopted by friend Alley, as described in his book. These queens were kept caged in a queenless colony, and let out of the cages one at a time. As soon as the queen released began to lay she was removed, and the next one let out, and so on. This worked pretty well while a flow of honey lasted; but when it ceased, robbers interfered, and finally the young bees got to pulling the legs and wings of the young queens through the cages. A double wire-cloth covering might have prevented this, but it seemed then almost too much machinery. Many of these things worked

nically while there was a steady yield of honey; but when the bees turn to robbing, the whole plan is impracticable.

In regard to introducing virgin queens as soon as they hatch, if I understand you correctly your experience is very singular. It is a regular business with us, day after day and month after month. We sometimes release from 25 to 50 in a day. I have just interviewed Mr. Kimber, our apiarist, and he says, after taking a tested queen out of a strong colony he has difficulty in releasing a virgin queen inside of 24 hours, but with a weak nucleus he seldom has trouble. As a rule, he generally leaves them about this length of time after taking their queen away, that they may become conscious of queenlessness. Then he lets the young queen in at the top of the hive, being careful not to disturb the bees; otherwise they might kill her. During this operation he does not look to see whether she is received or not, and not one in twenty-five is lost, treated in this way. He prefers to wait about 24 hours, rather than to take the time to go around and look them up to see if they are balled, which he would think best to do if he let them run in at the same time he removed the laying queen. We should be glad to hear from others who practice using the lamp nursery, or what Neighbor H. calls a "queen-hatcher"—a number of queen-cells placed over the brood-nest of a strong colony.

Now, then, let us not lose sight of the point; viz., some plan of introducing virgin queens from five days to a week old, and a plan that will permit us to put them in within 24 hours after the laying queen is removed. Of course, we should like to save this 24 hours, if we could, but it would probably occupy so much time that we can better afford to wait this length of time. Another problem is, Where shall we keep these young queens until they are five days or a week old? My experience seems to indicate that they ought to have a considerable amount of room in which to travel about, for their best development. A queen, as soon as she is hatched, commences at once to travel over the combs, and travels about incessantly, day and night, for the first week of her existence. I think she ought to have at least one full-sized comb for a promenade ground.

We have customers, too, who want queens of our own raising. Early in the season, when the greatest demand comes, of course we can not supply this demand. I have tried putting an extra price on queens of our own raising; but if we have got careful men in the South to rear queens for us, why shouldn't they be just as good as any raised here? During this present season, I believe our queens shipped us from the South have been just as good as those raised here, and the queen business this present season is away beyond any thing it has ever been before; and the demand for young queens just commencing to lay has been very much greater than for any other kind; in fact, a great many prefer such queens, *honestly raised*, to tested queens a year old or more, even if the price were the same. The hue and cry against untested queens seems to have passed almost entirely away.

HONEY-THIEVES.

A TERRIBLE PUNISHMENT FOR STEALING A FEW POUNDS OF HONEY.

JUST about one year ago I missed from one of my hives two 6-lb. boxes; in a few days after, there were two others taken, and in about a week there was a Langstroth hive missing one morning. Upon diligent search I found the hive behind the garden fence, with the honey all taken out, and the frames all taken away but two, the bees scattered around in the grass, and a great many of them trampled to death. It was a young swarm put on empty combs, and they had been there long enough to fill them all full of honey and brood, that I know, because one of my boys and I had examined it but two days previously to its being taken.

In about a month after, it leaked out that a certain man and two boys were the thieves, all belonging to different families. The two boys lived less than a mile from my farm. The younger boy was about 14 years old, and to him I concluded to go and tell him what I had reason to believe, and ask him to confess the crime and help me bring the others to justice. At first he denied it, but afterward agreed to turn State's evidence, if I would not prosecute him. I then procured warrants for the other two. The man was arrested; but the other boy saw the officer coming, and ran into the woods and subsequently to Ohio, and has never yet returned, that I know of. The man had an examining trial before two magistrates, was bound over under two-hundred-dollar bonds for his appearance before the circuit court of Lewis County, which was to convene the second Monday in December. As he failed to give bonds he was lodged in the county jail, and at circuit court he confessed the crime, and the jury sent him to the State penitentiary for the shortest term—one year, and where he now is, and will stay till the middle of next December. Our law sends a man to the penitentiary from one to five years, if he steals to the amount of ten dollars. I proved my loss to amount to about \$13.00. The boy who confessed, was the son of a widow, and he promised me that he would never be guilty of such a crime again; but I fear he is again at his old trick, or some one else is stealing on his credit; for within the past month I lost at one time two frames from the middle of a hive, and a little later three more, and within the past week three 6-lb. boxes.

The weather is very dry. Bees are not booming. I came through the winter with 14 stands out of 20; have now 24. Wheat is a failure; grass about half a crop. G. F. HESLTON.

Valley, Ky., July 6, 1885.

Friend H., this seems terribly severe; but I presume the warning will be a wholesome restraint upon others who may think of doing such a thing. Probably the honey obtained in the manner specified above would not have cost, if brought at the proper place, more than a couple of dollars at furthest; but the damage to you in the loss of bees and a valuable queen was probably all you stated, and perhaps more. I believe it is best, as a rule, to follow such matters up, and have the parties brought to justice. This man who led these boys into this scrape is stopped for the present, any way, and we hope for all time to come.

CLIPPING QUEENS' WINGS.

STRANGE ACTIONS OF A SWARM HAVING A CLIPPED QUEEN.

IN July No. of GLEANINGS, page 454, friend Doolittle, it seems, can not help but think the practice of clipping queens' wings favorable, where the apiarist is working his bees for comb honey. I have had some experience in working for comb honey with bees whose queens had their wings clipped, but soon gave up the practice.

About ten years ago I selected a few of my strongest stocks of bees, to be used for the purpose of producing comb honey. I found the queen of each hive, and clipped one wing of each one of the queens, and returned them to their hives. I remember one hive of hybrid bees, of the number I had selected, was stronger in bees than the rest. One day these hybrid bees cast a swarm. After the bees had left the hive I began looking for the queen. I found her five or six feet from the hive, hopping away as best she could. I caught and caged her. The bees did not cluster, but continued flying through the air in search of their queen. After failing to find her they returned to the hive they came from. As they were going in, I released the queen, and let her enter the hive with the bees. As I was working them for comb honey I concluded to let the queens settle their own business matters. The afternoon of the same day, that hive swarmed again. I found the queen as before. The bees, after flying through the air without clustering, came back to their hive. I released the queen, and they all went in together. The next day they swarmed again. I found the queen quite a little distance from the hive, trying to get away as fast as she could. I caught her and watched the bees. They flew through the air for some time, and returned to the hive, but did not enter, but clustered on a tree near by the hive. I thought there might be a young queen with them, and was about to get an empty hive to put them in. I observed the cluster of bees in motion, and it was no small bunch of bees either. In a moment they were all in the air again, coming for their hive, and went in as before. Then commenced the liveliest time I ever saw in a hive of bees. The bees came rolling and tumbling out of the hive, stinging each other to death.

I soon left that hive of bees, without much ceremony; for a while it was not safe for one to go near it. The battle lasted some time. The bees were cross all that day. That night the bees that were left cleaned house. In the morning the ground in front of the hive was covered with dead bees.

Since that season I have not clipped the wings of any more queens. Had that queen been a valuable one, I am very certain I should have let her had I been away from home. Of late years, when the swarming season arrives, and should I be away from home (and I usually am), I practice artificial swarming, and let the queens have their wings.

Canfield, Ohio, July 13, 1885.

A. S. PORTER.

Friend P., the stinging may not have been caused by the disappointment of the bees because the queen could not accompany them. Notwithstanding, it looks somewhat as if that were the trouble. I have never known bees to sting each other because they were baffled in their desire to swarm, but I have

known them to ball the queen, and kill her, and then swarm as soon as a young queen was hatched; and as they loafed around and did little work while waiting for the young queen to be hatched, it seems to me it was a rather expensive business for their owner. A great number of articles have been received in regard to this matter of clipping queens' wings, and we probably shall not have room for them all.

SHALL WE CLIP THE WINGS OF OUR QUEENS?

I clip all of my queens, and would not think for a moment of leaving them unclipped. As far as losing our queens is concerned, when the swarm issues, if we do not happen to see them, this is not worth spending breath about, as I now have 72 colonies of bees, and have not lost a queen on account of having them clipped, this season. I often find the queen has gone back, on going to the hive which is sending forth the swarm; in this case they will generally swarm again the next day. Of course, there will be a queen lost once in a great while, which loss I would not care for if I only knew the hive which lost the queen, and the date of the loss. I think I am safe in saying we shall not lose one queen by having them clipped, while we lose ten swarms and queens where they are not clipped. The reason I make this statement is, I have lost two swarms this season, which have issued unexpectedly with young queens. If you wish, I will give you my way of treating swarms where we wish as little increase as possible.

A. P. COWAN.

Grattan, Mich., July 12, 1885.

FRIEND REPLOGLE'S PRACTICE.

I clip my queens, and could not well get along without. I left a few unclipped last season, and they have given me more trouble than all the rest. One of them came out with a swarm, and started at once to take French leave; but with a vigorous application of dust I succeeded in settling them. Another went with the bees into the top of a tall slender maple-tree, whence they were taken with difficulty and some danger. When a swarm issues with a clipped queen I know where to find her and how to keep her. I seldom have any trouble to get them to settle in a convenient place, by hanging the cage containing the queen in some place where the bees in their flight will be passing around. They find her, I think, by the peculiar odor she possesses. It is only when bees are compelled to return to the parent hive in quest of the queen that they kill her. When a clipped queen gets some distance from the hive the returning bees set up the hiving-note, and she at once, with few exceptions, returns to the hive. This she will usually do two or three times before the bees kill her. To test the question of the queen's odor, I have often, after releasing her from the cage, hung the cage up a rod or more from where the bees had clustered, and they would find the cage and begin to cluster on it as though the queen were still within. I dislike the "artificial swarming" theory. I want my colonies strong. I will not, as a rule, have them divided until the bees will consent to nothing else. It would be better for the world of bee-keepers at large, if those who divide artificially had kept their pet theory to themselves. You know, Mr. Root, that when the bees have little or nothing to do during warm weather they will "hang out" more than at any other time. Then the unscientific bee-keeper concludes they are go-

ing to swarm, and hastens to divide his bees, and the result is frequently an entire loss of his bees, either by immediate robbing or by starvation in early winter.

G. B. REPLOGLE.

Udell, Iowa, July 13, 1885.

CLIPPING QUEENS' WINGS, ETC.

I see in July 1 GLEANINGS, page 451, Mr. Doolittle speaks about clipping queens' wings, and you call on the brethren for an answer. For my part I don't want any clipped queens. I have had two or three in my time, and that will do me. They made me more bother than a dozen unclipped ones. When they would swarm, then I would have to run and hunt for the queen, and about that time the bees were coming back to the old hive; then if I had her, the next thing was to move the old hive; and I think it is a pretty big job to pick up a hive that weighs all together from 50 to 100 lbs. or more, and get out of the way, or they would be right in again. I for my part never saw a swarm leave for the woods before it had clustered, and I have hived quite a number in my time, though it may be. I do not by any means say that they will not.

ALLEY'S TRAP.

In regard to the queen-trap, Alley's trap will be "boss" after you have a swarm in the hive. If you think it might not stay in, just place the trap at the entrance of the hive, and if they come out you will have the queen in the trap. It will do the work, for I had a trial of it.

The bees are doing very well just now. They are making lots of honey, but it is not quite as nice as it might be.

G. M. WAGGONER.

Carlisle, Cumb. Co., Pa., July 18, 1885.

CLIPPING QUEENS; STRAWBERRIES, ETC.

You ask about clipping wings. Let me put in my vote for it. The bees are doing very nicely now. Your experience with strawberries differs somewhat from ours this season. Perhaps it was in the soil, which is a heavy black loam, with clay subsoil, and was heavily manured. Our Sharpless were the poorest berry that we had. They ripened poorly, and rotted badly. True there were some very large berries, but not a *crop*. The Jucundas were our best. Give them a trial, Mr. Root, before you say too much about the Sharpless. FRED S. CLARKE.

Bowling Green, Ohio.

I vote *against* clipping queens, although I have had as high as seven swarms emerge at the same time.

LEONIDAS HUBBARD.

Waldron, Mich., July 10, 1885.

HONEY THAT CANDIES IN THE COMB AS SOON AS IT BEGINS TO RIPEN.

A SUGGESTION IN REGARD TO THE SOURCE OF SUCH HONEY.

MR. ROOT:—Be so good as to advise us what is best to do, in this case made and not provided for: Last year, through Mr. Porter we ordered from you an extractor, with which from twelve colonies we took four or five hundred pounds of honey. But this year, having fixed most of the apiary to be extracted, we found upon beginning, yesterday, that most of the frames are filled with candy. Some ten days ago we extracted over two gallons, which was very thin—some of it not capped over. We found one or two frames filled with young bees, which we gave to nu-

clei which we were building, and put in the place some frames of foundation. We thought we would wait a few days till the bees had finished their work. When we began again, we found all the honey gathered since that time candied, and the frames of foundation worked out and filled with this candy.

In GLEANINGS for 1884, p. 529, Mr. Lower, of Georgia, reports a similar case—at just the same time of year that we find it. I am sure it is the white sumac, for this is the only plant upon which the bees have been working for the last ten days, and from which they have been bringing in a large quantity of honey. I have seen ten or twelve bees upon one cluster of flowers. The black sumac will not bloom for two or three weeks yet.

Last fall we had extracted honey made from the black. It did not candy, though the winter was so cold, and it was in an open house. Now, what am I to do? I can't sell this honey in the frames, and to cut it out and muck it up will be trouble for nothing. I am going, if you don't advise something better, to cut it out and fix it in the section boxes, and let the bees stick it, and then put foundation in the frames, and see if they will continue their confectionery business this fall. If they do, I shall have to dispose of my extractor.

J. C. GORDON.

Joy Depot, Alb. Co., Va., July 13, 1885.

Friend G., I do not believe I would put any in section boxes. You will spoil the reputation of your comb honey. If you could keep it until you wanted stores during a dearth, I think the bees would use it all up in brood-rearing—that is, when you have a dearth during warm dry weather. Perhaps the process given on pages 458 and 459 of the July 1 number might assist you some.

THE TELEPHONE AS A SWARM INDICATOR.

AN ADVERSE REPORT.

SEEING a glowing advertisement in GLEANINGS, concerning the telephone as a success in swarming, I immediately made a rush for telephones, and received two—one running from the dwelling to the shop, and one from the shop into the apiary, which contains $\frac{1}{2}$ acre, in a square. My hives are set in a hexagonal form (50 of them at present), 10 feet apart each way. I ran the wire from the shop through the center of the apiary to the back part, being about 160 feet of wire in all. I fixed up the mouth-pieces, and had every thing in good working order. "There, now," I said to my wife, "I can work in the shop without having to run every few minutes to see if the bees are swarming. Now, boys, you can help your ma, and hoe in the garden, etc. We have got 'em fixed now. I know it will do it, for your Uncle Amos said it would," and so I gave a great sigh of relief as I sauntered toward the shop.

On going in I distinctly heard the wires ting, ting, and it sounded to me very nicely indeed. But I felt a little hurt to think the little fellows were bumping their heads so abruptly against the wires. I worked away, feeling probably as happy as I ever did in my life, when, in less time than I have been writing, I heard the alarm. But it was not the telephone. It was, "Pap! pa- ap! pa- pa! the bees are swarming!"

I made a rush for the bees, of course, and the boys

made a rush for the telephone. But I guess they didn't hear much, for the swarm came off at one side of the apiary, and came in contact with the wire but very little, if any at all. So I soon saw I must have more wires, and went to work and stretched two wires across the apiary, running them into the kitchen, as this is where our "standing army" is mostly located. But, no good. It will answer the purpose sometimes, but not to be relied upon; and, laying all jokes aside, I have lost two valuable swarms by just depending on the telephone. It is up yet; but I think this is the last season that my little pets shall bump their heads against any such nuisance. A. H. DUFF.

Creighton, Ohio, July 14, 1885.

Friend D., it seems to me you are condemning the instrument a little bit prematurely. If your bees spread out when they swarm as ours do, I can't see how they miss striking the wire—at least some part of the swarm; and even if one edge of it should come near the wire, you would have notice enough. Were not those two swarms a little bit erratic in their behavior? The wire should be about as high up as the bees usually go when they are whirling about, preparatory to clustering. I have never before heard of a report indicating that more than one wire was needed. The room ought to be rather still where the sounders are. In a shop where much racket is going on, no doubt they might fail to give notice. See friend Salisbury's report in another column.

WHAT I KNOW ABOUT THOSE SOUR- ED APPLE-SKINS.

IS THERE ANY THING RESEMBLING HONEY THAT
CAN BE MADE FROM IT?

BEING in the fruit evaporating business, I have had a few skins and cores to dispose of, so I will throw what light I have on the subject. It is without a doubt a fact that some of the drying factories do barrel up their skins and cores, and ship them to the large cities and sell them, but that is the extent of my information in that direction, as I have never shipped any off; but I am told that they go to the vinegar factories. From the refuse of 1800 bushels of apples last fall, I have about 40 barrels of vinegar now making, which is quite an important item in the business; for without that I should have been left last season, for the dried fruit did not sell for enough in market to cover the cost of its production. As to their making honey, or even jelly out of the skins after they can get them from the factories, I think it is rather mixed; for I have found that if the weather is any way warm, fermentation will begin in from 10 to 15 hours after they are separated from the apple. I have often noticed that a bushel or two taken off in the evening, if put in a close box or barrel, will be quite hot by next morning; and it is pretty well known that apple cider will not make good jelly, even if it will jell at all, after fermentation has started. But some factories are making a genuine cider jelly, and a splendid good article it is too, from apple skins and cores. It is made by boiling with steam, and in the wonderfully short space of three minutes from the cold cider to the finished jelly. No flavoring of any kind, nor any adulteration, need be used. The inventor of the

rapid process says that every thing used about the works must positively be kept scrupulously clean; and the stock to be used must be fresh; that cider even an hour from the press will sometimes start fermentation enough to prevent its jellifying. Yet I find these makers of pure jelly have as much to fight against in the markets as the honey-producers do; for the markets are flooded with all kinds of bogus so-called fruit jellies that are said to be made of glucose and coloring matter, and flavored to represent about or quite all of the real fruit jellies. I have never yet made any jelly, but have sometimes thought I would. A. A. FRADENBURG.

Port Washington, Ohio, July 8, 1885.

Friend F., be careful you do not fall into the same mistake we are trying to correct, when you intimate that our fruit jellies are adulterated with colored glucose. Are not the fruit jellies to be found in our groceries and stores made from genuine fruit, as a rule? Very likely some of it is poorly made, but that is not a crime like adulteration.

A KIND LETTER WITH SOME SUG- GESTIONS.

ARTIFICIAL SWARMING BY MOVING THE OLD HIVE
AWAY, ETC.

I HAVE tested all the queens that I have got from you this season, and, like all the others bought in former seasons, prove to have been purely mated, and two or three of your dollar queens that I bought this season would bring me a good price as fancy tested queens. I have never lost a queen in introducing, but I have been sadly vexed with the Peet cage. I prefer to fasten the cage on the comb without brushing off all the bees, and it works all right until I go to remove the tin slide when I find them fitted in so tight that it would tear the comb, cage, and all, to pieces. Now, for my use I would have the tin slide fit so loosely that it would drop out, and then secure it with a half-inch wire nail driven in the lap at the top.

My bees are doing well now. I lost about half in wintering. I bought some in box hives after they were too full of honey to transfer, and I divided them by moving them in the middle of the day and setting a hive with a caged queen in their place, as per instructions in ABC book, and the colonies I made in that way are the best for business of any in the yard, and it is the only plan that I could think of to prevent after-swarming with a box hive.

I planted 1000 strawberry-plants last spring. I followed Doolittle's instructions, as described in Feb. GLEANINGS. I like the plan excellently, and my plants are extra fine.

I must thank you again for your kind and prompt manner of filling my small orders.

Burnettsville, Ind., July 6, 1885. A. B. HERMAN.

Friend H., I am very glad of the report you give in regard to untested queens—not on my own account only, but because it speaks well for the friends in the South who have been supplying us. Queen-rearing in the South, before we can possibly get at it here in the North, is getting to be a growing industry. Some of the time during the present season we have been receiving at the rate of from 50 to 100 a day.—Your sugges-

tions about the tin slide of the Peet cage are good, and I will just now give orders to the girls to use no cages unless the slides are loose. The shrinking and swelling of the lumber has something to do with making them tight.—I am glad that you agree with me, that the plan given in the A B C book, for making artificial swarms, is a good one. It is so extremely simple, too, that I have often wondered why a good many prefer plans requiring so much time and machinery about them, to this one. We are glad, too, to know that you succeeded with strawberries so nicely.

AFTER SWARMS.

ALSO A FAVORABLE REPORT OF THE FOUNTAIN PUMP.

IN regard to prevention of after-swarms, I would say that I tried the Heddon plan, as given on page 411, about 25 times last year, and the same number of times the present year. It is a simple, practical method, and, if properly executed, will have as few exceptions as any other rule in apiculture. You are surely right in saying there is no *absolute* rule that will apply to all cases, with bees. To illustrate: In about 30 cases of "modern transferring," one colony would persist in killing the bees of the last drive, in spite of smoke, drumming, or mixing of bees. I consider it the best method of transferring ever published.

With the fountain pump we are not obliged to let swarms cluster where they please. Mine are always *made* to cluster in a convenient place, although the yard is full of very inconvenient ones. With black bees the following plan works nicely: Fasten any kind of a light box to a long pole, the opening at right angles to the handle, and provide it with two short legs, so that it can be set down without crushing bees. When a swarm issues, go to the nearest hive (an extracting super is best), take out a frame with adhering bees, and shake them into the box. They at once begin roaring, and when held just outside the center of the flying swarm, it will bring the cluster to them. The swarm is secured in less time than it takes to tell how to do it, and there is little danger of swarms uniting. If others issue, put the swarm in the shade and cover with a sheet of burlap. I have had swarms come so thick and fast that about one-fourth of each swarm was left to join the next. In this way a neighboring bee-keeper manages to toll the swarms right into the prepared hive.

HEDDON HIVES.

Please ask the friends to suspend judgment on the Heddon hives and fixtures until they have tried at least ten of them for a year or more, for they can't learn to appreciate their advantages, and use them properly in less time. The hive-covers are not meant to *slide* on, as described by Bro. H. Take the cover in both hands, bringing it down to place with a quick back-and-forth rotary movement, and it is adjusted instantly, without killing a bee. The propolis doesn't bother; they don't warp or blow off, and, if covered on one side with bits of comb or bees, turn them over and clean up at leisure. They need only to be used to be appreciated.

I have experimented with foundation as largely as possible the past and present season, and agree with Doolittle and Hutchinson, that much of the

fdn. used in the brood-chamber when producing comb honey, and during a heavy honey flow, is worse than wasted. Limit the brood-chamber to the need of the queen, and force the bees into the boxes at the start, and there can be no question as to the profitable use of the foundation.

I am using the "Heddon contracting method" (see A. B. J., page 437, 1885), altogether this season. It is a long progressive stride in the right direction, and will surely come into general use. Doolittle practices about the same method, I believe. I take great comfort in handling these honeyless brood-chambers. Five solid reversible sheets of brood, no crowded bulging combs or braces, and most of the bees come off with the boxes, and are out of the way when reversing or handling the combs. Now that reversible frames have demonstrated the desirability of reversing, practical honey-producers demand a reversible hive. Such hives must surely be invented before long; and so soon as one appears in the market, of practical construction, and one that does not do away with the laterally moving frame, I intend to adopt it. Take notice: My opinions are also subject to reversal as we progress.

DWIGHT FURNESS.

Furnessville, Ind., July 18, 1885.

POISON HONEY.

Some additional Facts and Suggestions.

CAUTION AGAINST TAKING HONEY FROM THE HIVES, BEFORE IT IS RIPE, ETC.

EDITOR GLEANINGS:—When Prof. A. J. Cook makes a statement, and is supported in it by Mr. A. I. Root, it seems almost presumption for any one to object; but it is possible for any one to be wrong. Prof. Cook says, in the last sentence on "Poisoned Honey," p. 445, that the "nectar which plants secrete does not partake of the qualities of the tissues." You think he has "struck the root of the matter." If this is the correct view of the matter, why do flowers have their own peculiar smell or flavor? If there is no connection between the juices of a plant and its nectar secretion, where does the peculiar aroma of each come from? We know that unless a tree or plant is rich in sap or juice, there will be but little or no honey. We know that honey secretion is directly dependent on a succulent, juicy condition of the flower, and that this condition necessitates an abundant flow of sap from which it can be secreted. Why, then, is not the honey from each class of honey-producing plants flavored by its own peculiar essence? I claim that it is. Why does not white-clover honey taste like that from the willow? Because of the pungency of the willow being lacking in the clover. I have been told here that willow honey is good as a preventive of fevers; that to use willow honey through the summer would be as good as a fever medicine. There is evidently a connection between its sap and its honey secretion, as is evidenced by a similarity in taste. If the honey didn't get its flavor directly from the juice in the flower, where could it get it from? What makes onion honey smell so rank when freshly gathered, and, when capped, be so much milder, yet possessing the flavor of onion nevertheless? Why can an experienced bee-keeper take sample after sample of honey, and, by tasting, say, "This is willow, this is white clover, this is smartweed, this is basswood, this is golden-

rod or boneset or mint or orange," etc.? Whence this ability to distinguish? What property in a plant can we look for to cause? Every honey-producing plant produces its own peculiar honey and no other, and this honey comes from its own peculiar juices, and partakes of the flavor of its own peculiar essence, and, to a greater or less degree, will be found to contain this essence. Unripe honey contains this essence in greater quantity than ripened or cap honey.

I lived some years on the St. John's River, in Florida, among the yellow jessamine. I had a few hives of bees one year, but did not get enough of the honey to know much about it; but the reputation of the yellow jessamine there was then that it is poisonous, and I was told by the natives that it had produced death. How and why, I think I can explain. When the natives got honey in the spring, they either got it by cutting a bee-tree or by "robbing" a box gum; and much of such honey, you know, would be fresh and unripened. You know, also, that people who are not accustomed to eating honey will almost always gorge themselves when getting it in such shape and quantity. A good portion of new uncapped honey of any kind, you well know, will be as good as a dose of pills, and those people not used to bees and ripe or unripe honey do not understand these things. Hence the use of honey is often much abused, and particularly so the yellow jessamine, which undoubtedly has poisonous properties to a certain extent when unripe. It is as good honey as any other when it is capped over.

It is a very great blessing to honey-producers that there are so few injurious honey-bearing plants in this country. Bee-keepers ought to be taught through the bee-journals this one thing: That honey is not fit to market until it has acquired a consistency which, had it been left in the hives, would induce the bees to cap it over. If any one has ever heard of any one suffering from eating capped or ripe honey, let him speak out. It is doubtful if such a case will be reported or can be verified. Let it be generally understood, that no honey is fit for sale that is not fit to cap. If the bee-keepers are not careful, those enterprising newspapers that know so little of honey adulteration, while pretending to know so much, will soon be saying that all the extracted honey in the United States, whether it be white, black, or green, is all yellow jessamine, and certain to kill on the first taste. When the time comes that all our honey is either glucose or poisonous, some of us will have to go out of the business. There are plenty of people of intelligence who, were they to see a statement in a newspaper, prejudicial to honey, would think the statement exactly correct, because it *was* in the newspaper, and bee-keepers should be bold enough to correct these lies whenever they find them. C. M. HIGGINS, 75—139.

Hahnville, La., July 7, 1885.

Friend H., by saying that the talk of Prof. Cook "struck at the root of the matter," I did not refer particularly to his concluding sentence. And this concluding sentence, I am sure, did not mean to convey the idea as you put it; but, rather, that if a plant were poisonous in its juices it would not necessarily follow that the honey secreted by its blossoms would also be poisonous. —I am glad of the additional facts you give us in regard to the yellow jessamine. I have eaten unripe honey in considerable quanti-

ties, but I never experienced any bad effect. Of course, I did not gorge myself with it, for my taste does not lie in that direction. —Are we not in danger of falling into an error, friend H. and other friends, in criticising too severely the course of the newspapers? They are on the lookout, of course, for items; and as their patrons seem to prefer sensational items, no doubt there is a temptation to cater to that taste; but as a whole, are not our newspapers the great educators of the day? What we want to pray for, it seems to me, is for more of a spirit of fairness and truth, and I suppose we all need it. I know for one I do.

LARGE BLACK ANTS.

Another Protection against Moth and Worms.

ALSO SOME FACTS ON AFTER-SWARMING.

GLEANINGS for July 15th came to-day. It always seems like a visit from a friend. I am still making bee-keeping a specialty, and therefore am obliged to make it pay. I try to keep my number at 100, or thereabouts, and have ever since 1873. I remember then you predicted that my enthusiasm would not last, and that I would give up the business. I trust I have learned something about bee-keeping since then. The article from Rev. L. L. Langstroth, on spiders preserving combs was given some years ago, and in 1879 and '80 I used them with success. I discarded them, and for three years I have used the large black ants, which I assure you are very energetic hunters, and will take moth worms out of their burrows. They make no litter, and do not cover combs with webs. To procure them, go into the woods, hunt up a rotten log having a nest of them, take a section with enough of them (say 200) to scour your room. My room is tight; the log is stood in a corner. They never leave it, but make daily raids over all the combs. In the absence of moths they can eat honey or drone brood. I wintered them two winters, and they cared for 300 combs.

I have tried Heddon's plan to prevent after-swarms. It will not always work. Last season it failed eight times, and this season six times. I have a plan which I follow which tends to weed out poor strains of bees, and at the same time prevents after-swarms, and ensures a large surplus yield. It is as follows: Stimulate all good strains early, and get them to swarm first. Make nuclei of their brood and queen-cells. They will hatch, and be laying by the time the other bees of the apiary swarm. When a swarm issues, take the old hive away and hive swarm on old stand, giving one frame of their brood; then proceed with the rest of brood to where one of your nuclei sat. Remove it, and place this hive in its place; then raise the frame with queen from nucleus, and place it in the hive. I forgot to say that I brush off all bees in front of swarm; the nucleus queen with the bees are at once a rousing swarm. The swarm has all the field-bees and many young ones besides. Both are ready to give surplus and all swarming is done for the season.

Clipping queens' wings, with me, still ensures their loss by their being superseded at once.

E. A. MORGAN,
the child that grew so fast.
Columbus, Wis., July 20, 1885.

CARNIOLAN QUEEN FROM FRANK BENTON.

SOME REASONS FOR DELAY.

ON Feb. 19th, this year, I sent \$7.00 to Frank Benton for a fine selected Carniolan queen, to be delivered during May. In about a month following I received a note from Mrs. Benton, acknowledging the receipt of my order, and stating that Mr. Benton had gone to Tunis, Africa, from thence to the Island of Cyprus, to Syria, and Jerusalem, and returning by way of Carniola. Mrs. Benton also stated that she could not promise the queen before the middle of May. Well, the queen did not arrive until July 13. She was mailed June 26th, and therefore was on the way 17 days I live 25 miles N. W. of Philadelphia. She was accompanied by 17 workers, of which 15 were dead; had consumed two-thirds of their candy. The queen is a fine large one, rather dark in color. She was successfully introduced, and commenced laying in two days after her release. The accompanying workers were of about the size of Italians, and the color (with the exception of a few, of a narrow dark-yellow band), pitch black. At the same time, I received a postal card, stating that it had been impossible to get off sooner any Carniolan queen, as there had been experienced great difficulty this season in getting them. He also gave me credit of one dollar, owing to the delay. Friend Root, I think this to be evidence sufficient to convince you of the inability of Mr. Benton to supply you sooner with Carniolan queens, although you had ordered nearly a year ago. I give him credit for supplying his retail trade first. I shouldn't think he would hold back your order for fear of having your judgment passed upon them, and scattered broadcast among Bee-friends while you have not yet seen any Carniolan bees. I will, as soon as some are hatched out, send you a dozen or so.

Hatfield, Pa., July 20, 1885. E. K. BLANCHER, M. D.

Thanks. In regard to wholesale and retail, I had no idea of getting a queen from friend Benton any cheaper than anybody else. I ordered two for fear some accident might happen to a single one. I thought very likely he was unable to fill orders sooner until notices came from different ones that they had received their Carniolan queens. It did not seem to me that their orders were older than mine.

MORE ABOUT THE CARNIOLANS.

On page 422, July GLEANINGS, W. W. Addison makes inquiry about Carniolan bees, and whether they hold out to Benton's description of them. For the benefit of those interested, I will state that I have found them to be all that Mr. B. claims for them, both as to gentleness and beauty. As for honey-gathering qualities, I am not so able to testify, for the simple reason that last year, on account of breeding for queens for myself and neighbors, and the season being poor, I did not get to try them. This year the honey crop, on account of drought (which I hope is but a local matter), has destroyed the prospect of ascertaining the fact; but from the manner in which they have filled their hives with brood, I have reason to think they will hold their own with other good bees, if not, to some extent, excel them. Last fall I took the imported queen and a couple of racks of bees to the Elkton, Md., fair. They were not entered in competition,

but merely as a comparison. From those who saw and handled them while there, I should like to hear an opinion. GEO. H. REESS.

Coatesville, Pa., June 22, 1885.

"MAKING BEESWAX."

MRS. HARRISON TELLS HOW THEY MANAGE IT AT THEIR HOUSE.

I DO not know but I have told how I make beeswax; but perhaps some sister has entered the GLEANINGS circle since, who would be benefited by a repetition. We keep in the neighborhood of one hundred colonies, more or less, and run mostly for comb honey, consequently have but little comb to melt—too small a quantity to warrant the outlay for a wax-extractor. We have not steam to use, as Mr. Root has, but only a stove. I have an all-metal sieve, which fits over a pan; into this sieve I put all bits of comb, and I save all scrapings, every mite. When it is full I put it into the oven when breakfast is being cooked, with water in the pan; and as it melts it filters into the water. The stove should not be very hot; if it is, the water and wax might boil over in the oven. Sometimes when I take out the sieve the residue is dry, like corn meal, and free from wax. I let the wax cool, and then pour out the water from under it. I never let my comb accumulate, but keep it melted up. I always scrape out the sieve every time into the stove and it burns readily. Saving every mite of wax is like saving paper-rags—too little business for most people; but it takes no more time than to waste it, and it is disagreeable stuff to be thrown down in an apiary, to be sticking to the feet, and thereby carrying dirt into the house. I think those who waste their scrapings would be surprised at the nice wax that can be obtained from them, even when there is not a piece of good comb.

After the comb is melted I know it is safe from moths, and so I let it accumulate, when I choose a cool day for re-melting. I choose a pan that will fit one of the iron stove-kettles. One that slips inside, and is held by the rim is best. In this pan the wax is melted over boiling water, with the pan covered. I melt out the ends of a fruit-can, forming a cylinder, which I use to hold a coffee-strainer. I set this cylinder holding the strainer into a small basin, and pour the wax into it; when the basin is full I take it off and set it into another one, and put it into the oven, to keep hot and drain. Before I use the strainer again I knock out the residue into the stove. I use the little pans that I bought for bee-feeders, and I rather like the wax in that shape. I let the wax settle a little while, and then pour it into a fresh pan, leaving the dregs. I keep all these utensils for wax, as it does not pay to clean them every time. I know a woman who melts up all her comb in a bread-pan in the oven, without any water, pouring it off through a hot coffee-strainer as fast as it melts.

MRS. L. HARRISON.

Peoria, Ill.

Why, Mrs. H., you have simply adopted our 35-cent wax-extractor. We sell the dish-pan and all-metal sieve, made so as to fit just right, for 25 cents. I commend your idea of having all the utensils you need kept together, and set away without cleaning. Whenever I see any of our girls trying to clean their utensils by scraping the wax off, I always feel like scolding.

HEADS OF GRAIN FROM DIFFERENT FIELDS.

EXTRACTING VERY THICK HONEY.

LAST summer was a very busy one for me, and I neglected to extract the honey from the colonies run for extracted honey, as fast as they gathered it, but kept taking out the filled combs and putting empty ones in their place. When the honey season closed I had a nice lot of sealed honey in brood-combs ready to extract, but had not any more time to extract it than during the summer, as I thought, so I stored them away and left them until so late that the honey became so thick that I questioned whether it could be extracted at all. But Doolittle, in GLEANINGS of Nov. 1, came to my relief, and told all about now to do it, and last week I tried his plan, and it worked to a charm, just as well as in warm weather, as far as I could discover, except that it had to be done by the side of the kitchen stove, and that is the women's domain; and, "look out" if you should be so unfortunate as to drop honey on the floor, and get it on the door-knobs, etc. After I had finished extracting I was so well pleased with the job that I said to the partner of my joys and sorrows that I would again subscribe for GLEANINGS, as I considered this article alone worth more than the subscription price.

By the way, the extractor I use is a home-made one, the gearing of which is made of an old-fashioned apple-parer, and it did not throw any honey over the top either, that I discovered. All it cost me was fifteen cents for the gearing, and my labor.

Williamsville, N. Y.

JOHN S. SNEARLY.

NAMING THE FRIENDS WHOSE PICTURES APPEAR IN THE PHOTOGRAPH MEDLEY OF THE NEW ORLEANS BEE-KEEPERS' CONGRESS.

On page 389, Jas. A. Nelson wants to know if we can not number the bee-keepers as they appear on our photograph taken at the N. O. Bee Congress. You seem to think not. Now, friend Root, suppose you commence, say at the familiar face of Viallon, on the left of the picture, but to our right as we face it, and call him No. 1, and Mr. Flournoy, of Texas, No. 2, etc., coming on down the line toward the very familiar faces of A. I. Root and Newman. There are just five lines, and numbering them from east to west, or right to left, we could affix the number, and let every man or woman call out his or her name through the journals. By this means I think we could very accurately get every name on the photo. I, too, should like to be in possession of all the names. I never expect to meet these faces again in the flesh, but I should like to have a card appended to my photo, giving all the names in full.

Clinton, La., July 7, 1885. W. F. ROBERTS, M. D.

A COLONY KILLS TEN QUEENS.

I have nine stands in Simplicity hives, all doing well but one. That one's trouble is, killing their queens in trying to build them up in the spring. They kill their queen, and I, according to your instruction, introduced another, and she laid one day and night, and they killed her also. I gave them brood and they raised one; she remained in the hive about four days, and she was killed also, and so on until they have raised and killed eight virgin queens and two laying queens, and they all have remained about four days in the hive before being killed. No eggs of fertile workers have been seen.

I have kept giving them brood to raise queens from, and they have kept up their colony very well. They have filled their comb with pollen, and yet they will have no queen. They have got queen-cells capped over now, and I suppose they will behave as before. Please tell me the cause and remedy.

Jordan, Ky.

A. C. CLOYER.

THE TURNER RASPBERRY.

I notice that Mr. Heddon, in his circular, recommends and also offers for sale the Turner as a great honey-producing plant. As I devote a little of my time experimenting, I will give my experience with the Turner. I have fruited it here three years without any cultivation. I find it very hardy; spreads rapidly, soon takes possession of considerable ground; canes are short, smooth, and thornless; plenty of bloom and ripe fruit at the same time, making its season very long. Bees are on it all the time, so that to get at any of its fruit or bloom would be much like trying to get hold of a balled queen. I think the reason the bees take the fruit here is, they don't find much honey before September. The fruit is rather soft for a distant market; but for a near market, or for home use, is excellent. I never saw so much fruit and bloom on the same amount of ground before anywhere, and I have been over 18 different States. I will here plant it on waste ground only, on account of its rapid spreading. We must experiment, in order to find out which fruits are best calculated for our soil; and while so doing, must expect to meet with some bitter disappointments. The Gregg and Cutbber, that prove so valuable in some parts of the country, amount to nothing on my soil.

STRAWBERRIES.

I believe that the Crescent will be my favorite strawberry; but, Mr. Root, I suppose that you will never plant it, because it often goes by the name of "Lazy Man's" strawberry; that is, being able to take care of itself on nearly any soil.

Nashville, Mo.

JOHN UMHOLS.

Thanks for your report, friend U. It seems to me that our best raspberries are now ready to take a foremost rank in our list of honey-plants. Raspberries, buckwheat, alsike clover, and rape can all be raised with a fair show of being profitable investments.

CARP.

In the fall of 1883 I made a pond about 30x50 feet, partly by excavating, and partly by damming across a hollow in which was a spring. Above this pond I made another dam, in order to throw the surface water into a ditch above, and run it around pond No. 1. I saw it would take but little work to make a smaller pond above No. 1. I did so, and made No. 2 about two-thirds as large as the first. On the 6th day of last May I put 8 two-year-old German carp into pond No. 2. On the 21st of May I saw the first young fish, about $\frac{1}{4}$ or $\frac{3}{4}$ of an inch long. During the summer I have taken from No. 2, 3000 young carp from 2 to 6 inches long, and put them in No. 1, and have sold 500 at \$5.00 per 100.

Minla, Ind.

T. F. WILSON.

GRASSHOPPERS ASSISTING BEES IN GATHERING HONEY FROM RED CLOVER.

Yesterday as I was passing through a clover field I heard the hum of bees at work; and stopping to look around I saw hundreds of bees of all kinds—blacks, hybrids, and Italians, busily at work on the

red clover. As I had never seen many bees working on the red clover before, I commenced to look closer, and found the cause to be this: The grasshoppers, which are very numerous here now, had eaten the flowers off even with the head, leaving the tube of the flower only about one-third long, thus giving every access to the nectar it contained. Bees have not done much so far.

I—IRA WILLIAMS, 4—8.

Georgetown, Iowa, July 4, 1885.

Friend W., the case you mention is novel indeed, and I believe it is the first time that I have heard of grasshoppers being of any use to anybody or any thing.

WHAT AILS THE BEES?—AN ANSWER TO INQUIRY ON PAGE 459.

C. D. Wright, on p. 459, asks, "What ails the bees?" I have had the same trouble, and think I have found out what it is. My bees last fall put in large quantities of fall honey, and some of it was left uncapped. This honey absorbed moisture, and soured in the cells. I have put these combs into the hives for the bees to clean up, and in all weak swarms the bees get drunk and tumble out of the hive. Some get over it and go back for more, but many never get back. I put in two combs to a swarm last evening, and this morning a number of bees were coming out staggering. Metheglin is too much for them, and they get out of the hive into the gutter, like human beings. This soured honey should be extracted before the combs are given to the bees to clean up. I think this soured honey has caused the loss of several nice queens for me this season.

East Saginaw, Mich., July 8. L. C. WHITING.

REVERSIBLE FRAMES.

Friend Root, I am rather surprised that you are in favor of, and bothering with, a reversible frame. "Localities differ;" but with us, any queen that does not fill with brood to the top-bar the shallow L. frame, needs "reversing," and usually gets it quick.

The situation at this date, June 24, with the beekeepers in eastern Indiana, is this: No surplus yet, and only a few colonies that have commenced storing in sections. Bees generally strong, but so far but very little swarming. Weather is unfavorable for the secretion of honey; white and red clover is mostly winter-killed. We still hope for some surplus, although the season here usually ends July 10th.

Our own bees wintered well; lost 5 out of 70, two of which the winter is not to blame for. We were never in more splendid trim, and ready for business, than this spring.

Lyons Station, Ind. JONAS SCHOLL, 65—70.

QUEEN-CELLS AND A LAYING QUEEN.

The two queens I bought were introduced safely; but had I written you about a week ago I would have said that one was killed, because a frame of eggs given the colony at the time contained five queen cells six days later. Would you please tell me why they started queen-cells when they had a laying queen? I can not find any thing about it in the A B C book. 2—GUST. WIEDERHOLD, 3—7.

Yonkers, N. Y., July 16, 1885.

Friend W., your case is one of the exceptions that occur once in a great while. I should say the bees were not quite satisfied with the other queen, and stubbornly pushed ahead with their preparations for raising another. Such cases are so rare, however, that,

in the presence of queen-cells, especially if at the same time we find no bees or very small larvae, it may be considered practically conclusive that the colony is queenless.

SOUR HONEY, AND WHAT TO DO WITH IT.

I have some sour honey, and do not know what to do with it; please tell me. Would it do to feed the bees? and if stored in the sections, would it do to sell? I looked through all of the bee-journals for a year and a half, and did not see any thing about sour honey. I also looked through the A B C.

Blue Springs, Mo., July 17, 1885. G. E. HUGHES.

Friend H., according to my experience the honey will not be made fit for use by feeding it to the bees, although they will often improve it considerably by taking it up and storing it in the combs. I do not know any thing you can do with it except to feed it a little at a time during a dearth of honey from the fields, to weak colonies or nuclei that will use it all up for brood-rearing or queen-rearing.

FROM BLASTED HOPES TO REPORTS ENCOURAGING.

I was almost a fit subject for Blasted Hopes last spring, having lost 75 out of 80 colonies of bees; but remembering that always after a storm comes the sunshine, I determined to try again. I bought 14 one-frame nuclei with tested queens, of friend Oliver Foster (who, by the way, is a square man to deal with). They have done extra well. I got them the 16th of May. All but two have cast very large swarms, and all have made more or less box honey—some 40 to 50 lbs. We got some white-clover honey—the first we ever had here. White clover is just getting started here. We are just through basswood, which was very good this year, and lasts with us eight or ten days. I had a hive on the scales during basswood flow. They brought in from six to eight lbs. a day, and during the night would evaporate about one-sixth. Did you ever know how much honey would evaporate? I have about 600 lbs. of comb honey ready for market now. I am selling at 20 cts. Have now 35 swarms. We get most of our honey here in August and September.

Hillsdale, Ia., July 18, 1885.

E. W. PITZER.

Yes, friend P., I did know that new honey during a damp spell of weather would evaporate fully as much as you mention.

CUTTING SMOOTH SECTIONS WITH A SAW ONLY, AND NO PLANER.

I read with great interest the article in regard to making smooth sections with an ordinary saw. Now, I wish to call your attention to the piece I herewith send you, as a specimen cut with a Simonds saw, 8 inches diameter, 20 guage rim, on a mandrel which has been in constant use for nine years, and has never been trued up or rebabbied. The saw originally had 100 teeth. I cut out half of them. The saw has been in use for two years, and has been set a number of times, and has a slight set now. It requires some care and skill to run a saw so thin as this; but it cuts so "sweet," and takes out so little, it is almost like cutting with a knife. The great secret about this smooth-sawing business, besides having dry straight-grained wood, is to give the saw time to do its work without crowding it. You may hear from me again on the section question.

S. Y. ORR.

Morning Sun, Iowa, July 4, 1885.

FRIEND SHERBURNE'S FEEDER.

I think I have a novelty of a feeder for spring feeding and stimulating purposes which I will describe for the benefit, may be, of some one. I bought the cheapest tin, 10x14, and cut het sheet into five strips 10 in. long, turned up the edges so as to make little pans $\frac{3}{4}$ in. deep, put two or three little slats lengthwise in the pans to prevent daubing the bees. The slats need not be nailed; spring the tin enough to hold them in place, that is all. Set the hive level, and slide them in at the entrance, under the combs. If $\frac{3}{4}$ in. is too deep, make them $\frac{1}{2}$ in., and a little wider; they will hold enough syrup, and will slide readily under the frames or combs of box hives. They can be drawn out by the fingers or a small hook; pour the syrup from a small spout, to prevent running the pans over. Whenever it is warm enough to feed at the top these pans can be used at the bottom, unless the colony is very weak; and for ease and convenience I know of no better. I have used fifty this spring. I am aware that they can not be used in every case; but I should make my hives so as to use them. Their chief merit is, that the top need not be uncovered and warm air allowed to escape; also labor saved in feeding.

ROLAND SHERBURNE.

Lone Tree, Ia., May 18, 1885.

SPASMIC CRAMP OF QUEENS AFTER THEY ARE CAUGHT BY THE WINGS.

Last night, about sundown, we (Mrs. M. and myself) were taking out some queens which were to be delivered next day, and we caught a very nice young Italian queen by the wings, very carefully, too, and she doubled up and died instantly. We then went to another hive (after again washing our hands thoroughly), and caught the queen in the same manner, and she acted exactly like the first one. We closed up the hive after having put both queens in on the frames of their hives, and left them until this morning, when I looked at them again. The first one we caught was as dead as ever; but the other one was all right, and attending to her domestic duties. Neither of the queens could have possibly got hurt any in handling, as we were very careful. Both queens acted exactly alike, and had the same treatment, and they were sisters, and both were laying queens. They had been laying for four days. Now, can you tell me what is the matter? I have studied your A B C until I can repeat it almost word for word, but can find no explanation for the conduct of those queens.

Pickering, Mo., July 9, 1885. G. B. McARTHUR.

Friend M., the above phenomenon is not unusual, and it has been before mentioned in the pages of GLEANINGS. I have never known it to result fatally before, however. But where a queen cramps and doubles up in this way, if she is placed back among the bees she straightens out all right generally.

MRS. HARRISON REPORTS A POOR HONEY YIELD.

The linden bloom has come and gone, and not one pound of comb honey has been taken off this season. This must be one of the "off" years, as the "dishes were all right side up" to gather it. The clovers are blooming, as it has been a showery season, but the nights are too cool for the secretion of nectar. Nearly every day bees are very busy for several hours in the afternoon. There have been but few swarms, and bees are not rich in wax, as they are during some years at this time. Old honey is nearly all out of market.

MRS. L. HARRISON.

Peoria, Ill.

AN A B C SCHOLAR GIVES HIS EXPERIENCE, WITH

A LITTLE PLEASANTRY.

I have had the "hen-fever," and got through it safely, and now I have got a slight attack of "bee-fever," from which I am not yet convalescent. A neighbor died very suddenly. His widow wished to dispose of his bees. To help out, I bought five swarms in old-fashioned box hives, and put them on an old bench, where they have wintered safely (no protection). Last week one hive swarmed. At first I said, "Let them go." They clustered on top of an elm-tree about 40 feet from the ground—an immense swarm. It seemed as large as a half-bushel measure. It was too big to be lost, and so with two of my boys we got up a ladder, cut off the limb, and put the bees in an old shoe-box. Then I drove across the country to a friend's—a bee-keepers even miles off, got an L. Simplicity hive, transferred the bees, and thus got "inoculated." I obtained your A B C book, to find how to treat the complaint; but it only made matters worse. The disease is spreading. I have built some hives have more under way; have been buying fdn.; have made a smoker; propose to transfer all the colonies to L. hives. I haven't got stung yet, but I don't crow any for fear I may. Excuse brevity (?). I only wrote to thank you for the information derived from your book.

Rye, N. Y., June 2, 1885.

A. M. HALSTED.

We clip the following from the *Canadian Bee Journal*, in the department of "Our Own Apiary:"

BEES CONFINING THE QUEEN.

A swarm issued at our home apiary. The foreman removed all the queen-cells except three, and no other queen cells remained in the hive, nor were there any more started. About fifteen days afterward another swarm issued. On examining the hive we found that the bees had actually kept those queens confined six or seven days after they should have gnawed out. One queen had been allowed to hatch, she leading out the second swarm, while the other two queens were in the cells, and, strange to say, the bees had seemingly continued to put wax on the outside of the cells until they were of an enormous size. We cut open the other two cells and liberated the other two queens. They were fine, and could fly as well as queens hatched several days. The wax was more than six times as thick as is usual on ordinary queen-cells. We do not know how to account for this strange freak of the bees; in fact, it is hard to account for some of the things bees do.

Friend Jones, the case you present is certainly novel. We do not remember that we have seen any thing of the kind in our apiary. It is a wonder that the young queens didn't starve, confined this length of time.

HOW TO MAKE A CAVE.

On page 343 of GLEANINGS, May 15, 1885, Mr. D. E. Brubaker asks how to make a cave. I will try to answer the question, not exactly how to make a cave, but a bee-house and cave combined, that will give better satisfaction in wintering bees, than a cave. My friend Julius Topell built a bee-house on this plan, and such a bee-house costs very little cash, only some labor that nearly every body can do who is brought up on a farm in a new country; viz., after the ground floor was excavated about 1½ feet deep, and drain laid (excavation 10 x 16 ft.), studs were set all around 2 ft. apart and outside of these another set of studs so as to make a hollow space 1 ft. apart. After the studs are boarded up with any common or old pieces of boards, fill up this hollow space with dry forest-leaves, then a top floor laid one foot lower than the length of studs;

studs are eight ft. above ground floor, a roof made of split red-oak shingles, one door on south side, one ventilator through the roof and down through the upper floor, and then four feet thick filled up all around with ground, a kind of stiff clay used in this case, so as to keep the earth in place as fast as the earth is filled in; a loose stone wall leans toward the earth, which is built all around up to the roof, on the upper floor (2 feet packed with forest-leaves) put in from the gable ends, and the gables boarded. Mr. Topell put in his bee-house, in 1883-'84, 3 colonies; wintered them all. In 1884-'85, 69 colonies 4 tiers high; lost only 4, and these were very small ones. The hive contains 7 frames of his own make, 8x13½ inches. He lost these by sheer starvation—too much extracting. Now, my suggestion would be for a man of more means to make the inner hollow space of brick, and the outside wall laid in mortar. A plate on this wall, and roof carried over the whole concern, and a double door 4 ft. apart on the south gable; such a building will last a lifetime. My bees are doing well.

Milwaukee, Wis., July 10. RUDOLPH BROWN.

BROOD IN SECTIONS, AND ITS RELATION TO SHALLOW FRAMES.

I inclose 27 cents for a sample by mail of your new perforated wooden honey-board. I had thought of using perforated zinc, but it strikes me that this wooden honey-board may have more stability, and be better every way. I need something of the kind very much indeed, to keep the queen out of the sections. When I used a frame 19 inches deep in the clear, it was very hard to get bees to work in top boxes at all. Then I went to work and cut them all down to eight inches, and, whew! nine out of every ten had brood of all kinds in the sections, including lots of queen-cells. All this gave me lots of trouble, and I am resolved to have no more of it.

Lynd, Mass.

P. R. FREEMONT.

FEEDING EGGS AND MILK; ALSO SOME SUGGESTIONS HOW TO MAKE BEES DEFEND THEMSELVES.

Dzierzon, on page 258 of his "Rational Bee-Keeping," tells us something about egg and milk feeding. I should like to know if it has been tried in this country, and how it works; how much to feed, and how to feed it. Would there be any sugar saved by feeding them? I wish you would tell all you know about it, as there will be more than one poor bee-keeper at his wit's end to know what to do in the spring, after such a poor season as this has been. We always have plenty of eggs and milk about that time of year.

I had quite a time getting my bees ready for winter. I had to feed 600 lbs. of granulated sugar, and they had robbing on the brain the worst I ever saw. Feeding is the best thing I ever tried, to make bees fight that won't defend their stores. Did you ever try it? If you didn't, the next swarm you catch that way, you try feeding them about one pint in the five-cent feeder for about two nights. If they don't spunk up, then stir them up the third morning, and leave the feeder in front of the hive a while. They will boil out to defend their old dry feeder when they won't defend their stores. After they get to fighting, take the feeder away, and they commonly keep their "dander" up. I worked several colonies that way last fall, and it never failed. I packed my bees in L. hives, with division-board, and forest-leaves at the sides, and chaff cushions on top. I wish I had the leaves out and chaff in their

place. I put them in when they were dry and brittle, and packed them in tolerably tight, and they drew dampness enough to make them swell and push the boards in some. B. T. BALDWIN, 25-43, Marion, Grant Co., Ind.

SOME EXPERIMENTS IN WAX.

As the question comes up a good many times among our bee-journalists and bee-keepers, as to the amount of wax contained in old combs, I will give you my experience in this matter. In my first lot I had 7 lbs. of comb, in about half of which brood had been reared once only. This yielded 5 lbs. of pretty white wax. In my second lot I had 3 lbs. of combs, all ages, from one to five years old; this yielded me 12 lbs. of nice clear yellow wax. In the third lot I had 17 lbs. of combs, old and dark, all of it; some of it I knew to be ten years old, and none less than two years old, and very little of it but that was six and seven years old. This yielded 4 lbs. of dark yellow wax.

From this it may be seen that new combs are almost or quite all pure wax; combs three or four years old contain about two-fifths wax, while combs six and seven years old only about one fourth or less of wax.

To cut up sheets of wax or foundation, use a butcher-knife, as you advise (sharp), and keep it wiped on a rag saturated with kerosene oil. This does not injure your fdn. in the least. In this way I cut fdn. easily, thirty to forty sheets high, clear through, without any more difficulty than cutting eight or ten sheets high, as there is no sticking, and you may cut as deep as your knife is long, or nearly so.

Goldsboro, N. C., May 24, 1885.

3. ARBOTT L. SWINSON, 41-59.

Friend S., your experiments are interesting as well as valuable. We should infer from your deductions, that it does not always pay to render up old combs.

HORSEMENT HONEY.

I send you, by to-day's mail, a sample of horse-mint honey. What do you think of it? and how does it compare, in your opinion, with white-clover and basswood honey of the North? What is it worth in the Northern markets?

C. A. WHEELER.

Brighton, Texas, July 11, 1885.

Friend W., your sample is beautiful—clear as crystal, good body, and beautiful flavor. There is just a little trace of that peculiar odd flavor especially belonging to horsemint honey, but it is so slight that I should think the honey ought to compare favorably with any clover or basswood honey made. In fact, I believe I should like a good dish full, like the sample you sent me, better than either clover or basswood; but I might in time tire of it quicker. I could not say what it would bring in the Northern markets, for there is a prospect that honey will have to be sold very low this season. See honey quotations on page 475.

RASPBERRY HONEY.

I send you a sample of honey made from red raspberry only. Bees don't work on white clover nearly as well as on red raspberry, which is roaring all day with bees. Don't be afraid to taste of it.

Cedar Creek, Wis., July 13, 1885. N. HANER.

Friend H., the sample of honey you send is beautiful. It is so much like white clover that I should be inclined to call it an extra-

fine specimen of clover honey, although it has a flavor slightly different when one notices carefully. I believe it is also of a deeper straw color than clover honey. If it is always like this, I should say that the honey from red raspberry will rank equal to any clover honey made, although the honey may be a little more "on the straw," as I have mentioned. Now, then, friends, we can get raspberries and honey too, therefore red raspberries are a safe honey-plant. We have just been sampling some specimens of the Marlborough raspberry. The plant is a wonderful grower. The berries are very large, and of excellent flavor. If full-grown plants fruit as well as our little ones less than two feet high, we want a big plantation of Marlboroughs.—We notice a good many speak of the red raspberry being especially a honey-plant. Don't bees get honey from the black raspberry also? We have not had an opportunity of testing it on our grounds. All that we have in full bearing are red, and the bees are extremely fond of them.

BEES BALLING THEIR OWN QUEEN.

Referring to Mrs. Harrison's inquiry on page 445, I should like to instance a case which has recently come under my own observation. I have a very fine and prolific Italian queen which was hatched last August, and wintered on three frames. Soon after spring opened this colony increased to eight frames, all filled with brood. About this time I commenced taking frames of brood from them for other colonies, giving them frames of full fdn. in place, and have kept this up till the present time. About ten days ago, upon opening this hive I noticed a ball of bees, and by smoking them I found the old queen in the center. After being liberated, she seemed frightened—running about on the comb, and was immediately caught by the bees and balled again—this time by a larger ball than before. As I was afraid they would kill her, I caught her and caged her in a Peet cage, on the comb, with the slide out. After a few days she was out attending to her business, and the bees all well disposed toward her. This colony was full of bees, with plenty of brood, honey, pollen, etc., and was in every way prosperous. I give you the facts; and as I am young in the business I will refrain from comments. C. W. COSTELLO.

Waterboro, Maine.

CARP FOR THE TABLE, AND HOW TO COOK THEM.

We have carp over here in Kentucky. They are wonderful growers, but they do not make a good bill of fare for every one, by any means. If you take them right from the pond and fry them they will taste of mud. I took one from my neighbor's pond, and it had a flavor of cold cabbage. This taste may have been given by feeding cabbage from the table, which I understand was done. If so, it shows that we may improve the quality of the fish by proper feeding. Indeed, we had about made up our minds to keep them from our table, but lately we have been successful in preparing them. We now kill and dress, and scald the skin off, as you would a cat-fish; then put them in salt and water until next day, then bring to a boil in clear water. Now bake or fry, and you have a very good fish, but not equal to the best fish of our county. We had one to-day for dinner, weighing about 5 lbs., prepared in this way, and it was pronounced a very

good fish. If you have any better way of preparing them, please let me know. H. C. HERSPERGER.

Keene, Ky., July 13, 1885.

Friend H., I think if you will try feeding your carp on some other kind of food shortly before they are taken for the table, you will find the quality of the flesh all that you may desire. This matter is very fully treated in the A B C of Carp Culture. You may have corn-fed fish as well as corn-fed beef.

HOW THOSE STRAWBERRIES TURNED OUT.

In April, 1881, I put out a whole town lot, which is 50 ft. wide by 150 ft. long, in strawberries, of which I had 17 different varieties, all of highly recommended kinds, of which the James Vick has been a total failure; the Windsor Chief, the largest berry; the Manchester the very latest, and a good bearer; but the old Wilson and the Crescent have been the most profitable, both affording good berries from the first to the last, and both kinds producing more than double what the most of the other kinds have done. Well, this is how they turned out: I have to-day, July 4, picked and sold 22 quarts, which is the last. Total, 666 quarts, or 20 bushels and a half, all of which have been sold or used at home, except 48 quarts shipped to Dennison. Average price 10 cts. a quart. Largest picking in one day, 84 qts. Next.

A. A. FRADENBURG.

Port Washington, O., July 4, 1885.

COOK'S BEE-BRUSH.

Many of the friends have declared they much preferred the old style of bee-brush invented and manufactured by our old friend T. J. Cook, and we have just made arrangements to furnish them again, as well as the Davis brush, which is just now having such a large sale. The letter below explains the matter. It also tells us something about how to use either the Cook or Davis brush.

THE COOK BEE-BRUSH.

We give a cut of the Cook brush as it was made before he died; and in accordance with friend Davis' kind offer we are prepared to furnish them at the same price as the Davis brush; namely, 15 cts. each. If wanted by mail, 3 cts. each extra for postage.

I send you by this mail one of Cook's brushes improved. When you get it unwrapped take out the tack, put in the handle, drive in the tack again, then dip the brush in water up to the head, then smoothe it out with the hand and let it dry, and the brush is ready for use. I send it that way to prevent getting broken in the mails.

Theodore J. Cook was a cousin of mine, and an only child of James and Elizabeth Cook. He was as fine a young man as ever marked this country, a member of the Methodist Church, and I think a true Christian. His parents are very wealthy, yet Theodore never indulged in any thing bad in his life; and, friend Root, you have no idea how it would please uncle and aunt to know that his brushes are still wanted. C. F. Muth thinks they are ahead of my brushes yet. J. S. C. DAVIS.

Ballstown, Ind., July 4, 1885.

LOW PRICE OF HONEY IN CALIFORNIA.

There has been a large amount of first-class honey sold here at $3\frac{1}{2}$ cents per lb., to be shipped to Europe—a very low price, I think, as a case with two cans costs a dollar cash, and each case had to be strapped with strap iron at both ends and middle. There is supposed to be a large amount of honey in first hands yet, in this county. I have on hand about five-sixths of last year's crop, which I feel inclined to hold for a better price than the above. I disposed of a small amount of honey at the stores, for whatever I can get; take pay in trade, no cash. Although honey is so cheap, the storekeepers tell me that they sell 10 or 12 lbs. of syrup to 1 lb. of honey. I wrote recently to England to inquire about the prospects for disposing of honey there, but I am advised not to send any honey there, on account of so much adulterated honey that has been sent there. The English are suspicious of all foreign honey. Several of my neighbors have sent honey to the Eastern States, with results rather discouraging. Can you give us any late information about the practicability of the Stanley automatic extractor? CHARLES WEST.

San Bernardino, Cal.

A LITTLE "PLEASANTRY" IN HIS EXPERIENCE IN WINTERING BEES.

I lost all but one swarm last winter, wintering on summer stands. I think these open winters (open to criticism) are very hard on bees left on summer stands. We have a very good winter-house in which we have wintered our bees several winters very successfully. It is warmed by steam-heating pipes, and the temperature is never as low as freezing. But as others were wintering on summer stands with apparently good results, we were induced to try the experiment, expecting, of course, we should have an open winter. Well, we have got the experience; but, the bees! oh, where are they? I really don't know, unless they are in somebody's apiary who has exercised a little more judicious care and judgment than I have. But I want some bees, even if I do feel somewhat guilty of committing bee-slavery in the first degree.

I am not keeping bees for a business, but merely for the pleasure of it. I am very fond of the saucy little imps, and I like very much to work with them when I have the time to spare. I am superintending a large oil-works here, owned by Mr. E. E. Clapp, of President, Pa., and my time is nearly all occupied in that direction; but still I find an hour or two nearly every day that I can give to my bees.

W. G. SAMPSON.

McGraw, Warren Co., Pa., May 18, 1885.

SETTING HIVES CLOSE TOGETHER; ALSO SOME FACTS AS TO WHETHER BIRDS KILL BEES.

GLEANINGS especially mentions the setting of hives close together. Well, I do it. Yes, after reading all that GLEANINGS has said in regard to it for the past three years. I use scantling 2×3 inches, and 16 ft. long, raised 10 in. from the ground on brick pillars, as benches on which to set my colonies and nuclei of queen-rearing hives. Of my full colonies I usually set 9, facing all the same way, on one of these 16-foot benches; of the nucleus hives, which are made to hold 6 L. frames, with a partition between each three frames, and a hole bored, one at each end, into each nucleus, so that one nucleus in these double hives works out back and the other

side front, I set 8 of these double nuclei to a 16-foot bench, thus having 16 three-frame nuclei on a 16-foot bench, entrances being about 2 ft. apart, front and back. They are mostly of one color, too, but I don't think that is advisable. I should prefer to have each alternate hive of a different color. I have never had any trouble with my full colonies, set as above. Out of 100 queens reared and mated from my nuclei so set this spring, I have had only two lost, or had four queens disappear before they began to lay, after being hatched. I think the most of our queens which disappear before laying do so because they are caught by birds and insects. During last September and October I lost nearly half the queens I had hatched out from my nuclei, before they began to lay; so this spring I kill all the bee-martins and any other birds that I find around that are catching any bees. Hence I have lost scarcely any queens from my nuclei. I have them all numbered, and I keep a record of the time of hatching out, the first eggs laid, the taking-out of a queen, the giving of a cell, etc.

3—ABBOTT L. SWINSON, 44—55.

Goldsboro, N. C., June 12, 1885.

Friend S., your arrangement will work very well, providing you do not have your rows too long. For instance, where the row is only 16 feet in length, the bees will count, as it were, the number of their hive from each end. Should you continue this row 100 feet, however, I think you would find that, with the exception of a few near each end, the rest would all be mixed up.

SOME UNUSUAL EXPERIENCES IN QUEEN-REARING.

Last year I wrote you an item concerning a rather unusual performance of a queen, published in Nov. GLEANINGS. From your remarks, I see you misunderstood the case, and intended to correct your impression before. While painting a cover, some of the paint ran through the cover and fell on some of the bees, the queen among others. The next day they swarmed, I put them in a new hive. Two days later they showed great agitation, as though they had lost their queen. The day following I found twelve queen-cells started; and on opening the old hive I found the queen there. The odd thing was, not that the queen was marked (though perhaps it was odd that she should be one of the dozen marked), nor that they started twelve queen-cells, but that, two days after they swarmed, the marked queen was with the swarm in the new hive. I saw her there, and the next day she was back in the old hive, and the swarm still stayed in the new hive. She was a pure Italian daughter of an imported queen; the queen the swarm raised was a hybrid.

A few days ago, finding a three-year-old queen giving signs of failing, and that there were several queen-cells found in the hive, I concluded to let the bees raise a queen; but fearing that the new queen might inherit her mother's weakness, I removed the cells and gave them a frame of brood with cells from one of my best queens. The cells were sealed. Four days later I found they had started three new cells, and had sealed them. I removed these; and seeing that they were rather shorter than common, I opened one of them. It contained a live worker, sealed up head down. The bee was just able to crawl when I released her.

A neighbor some time since had a queenless colony. He gave them at different times over a dozen

queen-cells, but they tore them down before the queens hatched. He gave them brood and they started cells, but tore them down before they hatched. He introduced four virgin queens, and they destroyed them all. Finally, finding a queen-cell remaining after it ought to have hatched, he opened it and found a worker-bee sealed up, head down.

S. J. BALDWIN.

Nelson, Ohio, July 13, 1885.

REPORT FROM OUR NEW \$6.50 LAWN-MOWER, ETC.

I received the lawn mower and scale in ten days after being shipped. The mower is all you recommended it to be. I cut grass that was four or five inches tall. I have thought a good many times I would write and see why you did not keep one for sale, for I knew you could sell one for less than \$12.00. That is the least you can get them for here.

Bees are doing well here. I have one swarm and will make 125 lbs. honey in 1-lb. boxes; some that gave two swarms that will make three crates, each 28 boxes per crate. New swarms are doing just as well. Some will make from two to three crates. I shall have lots of honey.

5—Geo. E. JONES, 18—45.

Northfield, Minn., July 25, 1885.

ADULT BEES CAN SECRETE WAX.

SOME INTERESTING EXPERIMENTS WITH THE OBSERVATORY HIVE.

FRIEND CONNELLY proves to his own satisfaction that worker-bees can *not* secrete wax (see pages 164 and 165, current volume); but if he will repeat my experiment he may be convinced of his error. On the morning of June 6th I placed in my observatory hive one frame of brood about three-fourths capped, and one frame of eggs and larvae, brushing off *all* bees; then watching my opportunity when no bees were flying about a certain colony, I closed the entrance and removed the hive to a new stand, setting the observatory hive in its place. The returning workers, after much hesitation, finally entered, took a careful survey of both combs, deposited their loads, and departed for others. But they soon discovered that this plan would not meet the emergency; for about an hour after, I observed that many bees remained on the combs; and at 3 p.m. both combs were quite covered. Next day many bees were hanging in festoons, and the 8th inst. all the brood was capped, and two queen-cells nearly completed. The four following days were stormy, and I took no notes. On the 13th instant I found the two queen-cells capped, and also about half of the larvae. Now, as none of the brood in the nucleus had been hatched yet, is it not evident that worker-bees can secrete wax, and act as nurses? It is evident that *old* bees will participate in this occupation; for during this time, outside operations were almost entirely suspended.

BEES CAN TRANSFER EGGS AND LARVÆ.

Last month my observatory hive gave me an opportunity of witnessing the transfer of a very young larva from the lower edge of one comb to an empty drone-cell, situated a little below the center line of the comb in another frame. A queen cell was completed, the queen hatched in due time, and is now laying. I have long suspected that bees could transfer; but this is the first time I could "catch them in the act." So much for an observatory hive. From many incidents in my experience I have concluded

that bees prefer forming queen-cells near the center line of a comb; and if the larvæ at that place are too old, the bees will either transfer, accept a "laying worker," dwindle, or abscond. The exception only proves the rule.

THE ADVANTAGES OF A SLANTING ALIGHTING-BOARD.

Brother Heddon says, "I find no gain in having a slanting alighting-board for bees" (see p. 84). He is a bold man who will venture to run a tilt with so noted a warrior as Bro. H.; but I have no fear; for "thrice armed is he whose cause is just." Notwithstanding I will "call a parley," and say, "Come, let us reason together." Every careful observer of the habits of the "busy bee" must have noticed that it always alights, if possible, on its hands (*i. e.*, front feet), and never on its feet (hind legs)—please excuse the Hibernicism—evidently, and for very good reasons, being very careful of its abdomen. When approaching a hive it slackens up; its body inclines to an angle of about 45 degrees, in which position it is easier to alight on an inclined or perpendicular surface than on a level. If Bro. H. will spare a few minutes from his active duties he will probably notice, as I have, that many bees will alight on the extreme outer corner of his level board, and leisurely walk into the hive; whereas, if there were a slanting board or a two-inch auger-hole, they would alight at the very entrance. Furthermore, a slanting board is always dry, which can not be claimed for the level board. For these reasons I have adopted, after many adjustments, an alighting-board 2 inches wide, $\frac{1}{2}$ in. thick, and 20 $\frac{1}{4}$ in. long, nailed at an angle of 45 degrees, just 3-16 inch below the upper edge of a similar strip, which has three saw-kerfs 3-16 inch wide and deep in said upper edge, and is fastened by two small screws to the bottom-board of my Simplicity hive, flush with its upper surface. The hive can thus be readily adjusted for the entrance of three worker-bees only, when desired. I admit, that it is easier for the apiarist to adjust the entrance by means of the triangular blocks, instead of sliding the hive forward or back; but I dislike so many loose traps, and have an especial care for the comfort of my bees. If Bro. H. has adopted the level board after fair trial, I can't expect him to apostatize; but I think many others in the fraternity will prefer the slanting board for the reasons stated.

T. WALDRON BARTHOLOF.

Honolulu, Hawaiian Islands, June 15, 1885.

Thanks, friend B., for the valuable facts furnished. I have for years been satisfied that the laboring bees from the fields, and even old ones with ragged wings, can secrete wax, and rear queens too, when forced to. We have been for a long time aware that bees can transfer eggs and larvae, although I do not know that any one before has seen them doing it.—From your description we infer that you allow the bees to enter your Simplicity hives from the side instead of the end, although you do not say so. I, too, should prefer a slanting alighting-board, if we could have them without too much expensive machinery. The alighting-board figured in our A B C, you will notice, has a slant on the front edge of the three-cornered blocks; and as we usually have the sand just below the alighting-board on a slant, it seems to answer the purpose. The alighting-board to the chaff hives is always made at an angle of 45 degrees.—Your plan

of arranging the entrance, so you can easily contract it so as to admit only three bees, is very good; but when you get to admitting more than three you are obliged to give the entrance the whole length of the hive—nearly 20 inches. Is not this a pretty broad passage-way? I much prefer to slide the hive backward and forward, in place of having loose blocks.

BEE BOTANY,

OR, HONEY-PLANTS TO BE NAMED.

WILD DESERT-CURRENT.

HEREWITH send a specimen of wild desert-current, which is at this date blooming to its fullest extent. I now send blooming branches, and in April will send fruit. A shrub or bush from 3 to 6 ft. in height, forming a dense bunch from 4 to 10 feet in diameter—that is, a single root—will have from 50 to 200 stalks, the size of your finger. The foliage is evergreen, leaves thick and fleshy; small twigs, spinous, like the twigs of an apple-tree; fruit, when ripe, a beautiful cardinal red, many-seeded, like a gooseberry or currant; oblong in shape. The bloom secretes an abundance of delicious nectar which my bees are now appropriating very rapidly.

J. L. GREGG.

Tempe, Arizona, Feb. 16, 1885.

Prof. Devol says of this plant:

The wild desert-current from J. L. Gregg, is properly so called. It is a species of *Ribes*, closely resembling *R. aureum*, Ph., the Missouri, or golden currant, and is perhaps a variety of the latter. Nearly or quite all the members of this family (*Saxifragaceæ*) produce an abundance of bee-food. It is hard for us to realize that it could be in full bloom there in the middle of February, when here in Central Ohio the thermometer was ranging as low as 20 degrees below zero. The Missouri currant blooms here in April and May.

W. S. DEVOL.

Columbus, O., March 7, 1885.

I send you a plant to be named. The common name is "arrow-bush," so named because the Indians here all make their arrows of the switches, which grow very straight. It is a bush or shrub from 4 to 10 ft. in height, and it grows mostly in the sandy river-bottoms, making a dense jungle of evergreen brush, sometimes hundreds of acres in extent; and were it not for the plow it would take our upland farms, owing to the seeds being winged (or having a tuft of cotton attached to each seed). They are borne by the winds all over the country, and readily germinate when the ground is irrigated. It bears a reddish-purple flower which secretes a great abundance of nectar, almost limpid. I think it is equal in quality and quantity to the far-famed basswood. When my bees were at work on it I extracted every third day, and the honey was much thicker than basswood. It bloomed about the first of last April, and continued in bloom till near the first of June; but the last two weeks the honey became so thick that the bees quit it for the mesquite and cat's claw, two honey-bearing trees of the locust family; but it again came in bloom the latter part of Nov., and continued till some two weeks since, when we had a cold spell, the mercury indicating 32° above zero, which stopped the blooming process, as you will see by the specimens sent.

Some of it contains seeds and flower-buds unopened, but I send two bunches of flowers wrapped in a separate paper, and placed inside the package.

Tempe, A. T., Jan. 19, 1885.

JNO. L. GREGG.

Prof. Devol says further:

The specimen from Dr. Gregg, of Arizona, was duly received. The flora of the West is not all worked up well, and it is not always easy to determine what a specimen is; and in this case I was unable to identify it. I therefore sent a part of it to Dr. Gray, to get his opinion of it; and in awaiting a reply I caused this long delay. It is a species of "Marsh fleabane" (*Pluchea borealis*, Gray), not described in the older botanies, but found in Dr. Gray's new work, "Synoptical Flora of the U. S."

They are strong-scented plants; growing very persistently, mostly in wet or moist places. The bright-colored pappus gives the plants the appearance of being in bloom long after the flowers have faded.

W. S. DEVOL.

Columbus, O., Feb. 19, 1885.

Please find a specimen of what seems to be quite a honey-plant in this section—the Upper Sierra. It is remarkable for its singular beauty. My bees have been working on it since early in April. It produces honey and pollen; is an evergreen, and a shrub, about one foot high. There are hundreds of acres of it around here. I do not know the botanical name for it. They call it tar-weed here. It grows along what is called the snow-line of the Sierra, and many times is six or seven feet under snow, but comes out as fresh and green as if it had been summer all the year, and puts forth its modest little flowers at the first appearance of spring. I have started in the bee business as an experiment here in the Sierra Nevada. I think there are some valuable honey-plants here. I am the only man in the county who is keeping bees for a business. The winter is no problem here, as it never gets to zero. We have deep snows, but no frozen ground. I will report on my success at some other time.

G. W. COVER.

Douneville, Sierra Co., Cal., June 12, 1885.

Concerning this plant, Prof. Devol says:

The inclosed plant from Colorado is called by Dr. Gray *Chamaelirium foliolosa*, and is a plant I know nothing about. From the small specimen sent, it looks as if it were a very pretty shrub.

W. S. DEVOL, Botanist.

Columbus, O., July 6, 1885.

WHITLOW GRASS.

Inclosed you will find a sample of a weed I send you. Please tell me what it is. It puts up in the winter; begins to bloom in February, and lasts till April. Bees do not gather pollen from it. I will give you more information in regard to it when it is through blooming. I will send you some seed of it when it is ripe.

J. W. RANSAVILLE.

Brandon, Texas, March 18, 1885.

Prof. Devol replies:

The plant referred to above is *Draba*, or whitlow-grass (*Draba cuneifolia*, Nutt.), an early-flowering low herb of the mustard family, found south and west. It is hairy, leafy at the base, and throws up several racemes of small white flowers, 3 to 8 inches high. The petals are about twice the length of the sepals, notched at the end. One of the earliest-flowering plants.

W. S. DEVOL.

Columbus, O., March 25, 1885.

FALSE STATEMENTS IN REGARD TO THE HONEY BUSINESS OF OUR COUNTRY.

As a protection to our bee-keeping population, we propose in this department to publish the names of newspapers that persist in publishing false statements in regard to the purity of honey which we as bee-keepers put on the market.

PLEASANTRIES THAT MAY BE DAMAGING.

THE following is perhaps deserving of a place in the column of False Statements. It is taken from *Form and Fireside* (Springfield, Ohio), issue of May 1, 1885, page 268, under head of "Little Bits."

"Why do bees make wax?" asks a farm journal. We do not know, unless it is because no one has told them that the honey manufacturers are willing to make it for them out of paraffine.

Of course, this is a pleasantry; but nevertheless it carries the same harmful impression as if it were stated in sober earnest. The publishers of *Form and Fireside*, a paper so sound and practical in its agricultural teachings, should not give circulation to such false reports, even in jest; for the mass of the people will take it as a fact, that honey is manufactured, and will accordingly be prejudiced against it. If I mistake not, they have a good many bee-keepers on their subscription list; and at one time you advertised with them. I think that they will be ready to correct any such statements which are so damaging to our business.

SAMUEL A. MILLER.

Newark, N. J., July 9, 1885.

Friend M., I agree with you. It is wrong to repeat or allude to any piece of scandal in jest, even though the parties who write may be fully aware that it is a fraud and a humbug. Thousands of people suppose that it is so, that comb honey is made out of glucose and paraffine.

MORE ABOUT PARAFFINE AND GLUCOSE COMB HONEY.

Imitation honey is made of paraffine comb filled with glucose, according to the *Scientific American*, which has analyzed several samples.

This paragraph needs retraction. I take much interest in reading "False Statements," especially as you put them. I think all bee-keepers should have the eye of an eagle, to discover and point out such false statements, and let us show them up and make every publisher retract the libel, or give them a standing advertisement in GLEANINGS.

Harrisonville, N. J., July 6, 1885. J. D. COLES.

Thank you, friend C. If any of our readers have noticed any such statement in the *Scientific American*, they will confer a favor by telling us what number and page. The editors of the *Scientific American*, above all other men, ought to inform themselves of the truth of such statements before giving place to them. If they have actually analyzed samples of comb honey, and found them as above, we want the full particulars of the matter, no matter what it costs to hunt them up. It seems it is not the daily papers alone that are searching for something sensational. I know it is quite a temptation to repeat such things as are sure to create a sensation, when it is so much easier to do it than to hunt up established facts.

THE NEWSPAPER AS AN EDUCATOR (?) ON MANUFACTURED HONEY.

Editor GLEANINGS:—Can you not propose some plan of management by which I can obtain new

comb for starters in sections? I have on hand plenty of thin foundation for that purpose, but many consumers object to its use, even if they are unable to detect its presence in the comb. Lately I have been at some pains to introduce the subject of manufactured honey in conversation, and I find that many of our most intelligent citizens firmly believe that a large proportion of the comb honey sold in our market never saw the interior of a beehive. So much for the newspaper as an "educator."

Bees in this region have made only a living, up to this date—nothing more. There is not yet enough white clover growing here for us to get any surplus from that source. A short period of fine weather three weeks ago brought out some swarms; but cold rainy days followed, and I have had to feed. Basswood gives promise of a good yield, judging from the loads of buds. Z. T. HAWK.

Denison, Iowa, June 25, 1885.

Friend H., you can obtain new comb for starters by putting thin foundation in brood-frames, and hanging them in the center of the brood-nest until the bees get their cells drawn out. Mr. W. B. House gave the plan at length two or three years ago, and he obtained an enormous yield of comb honey, which he thinks was mainly secured by this plan.

NOTES AND QUERIES.

A REPORT RELATIVE TO FLAT-BOTTOMED FDN.

IHAVE been using flat-bottomed foundation, thin, 14 feet to the pound, in small quantities, about one to two inches deep in sections, and I find when I spread it on bread or cakes (I mean pan-cakes) I can not break up this foundation. I have never used any of yours; but if such is the case, I do not like artificial comb for sections—only a very small piece. G. A. MATHEWS.

Katonah, N. Y.

Bees drop with a thud on the alighting-board.

Bates, Ill., June 19, 1885. I. R. MORRISON.

STRAWBERRIES BY THE BARREL.

Those strawberries in the barrel that you requested me to report about (p. 243) were a complete failure. They froze out entirely. W. S. DORMAN.

Mechanicsville, Ia., July 7, 1885.

UNEXPECTED APPEARANCE OF A BLACK QUEEN IN A NUCLEUS.

In my last I mentioned a nucleus which swarmed out and then returned to the same hive. It was without a queen, and I asked you if you could explain their doing so. You can imagine my surprise, two days after, to find they had got a black queen in with them. Now, how is this to be explained? I will guarantee there were no queen-cells in the hive; and besides, I have no bees except what I have got this spring from Viallon and yourself, and there are no black bees in the immediate neighborhood. If you can, please help a novice by explaining how this came about. J. N. KENDALL.

Ilderton, Can., July, 1885.

[Friend K., I think you are mistaken about the queen being of black blood. She is small and dark because she was raised under unfavorable circumstances; but when you come to see her progeny I think you will say they show the Italian blood. Or she may have been a queen that got into the hive by mistake on her return from her wedding-trip.]

WILD FLAX.

Did you know that wild flax is the best kind of bee-fodder for fall? When I was cutting oats that were full of it, all the bees in the vicinity were on it and would stick to it after it was laid down, and the honey is No. 1.

E. J. HAND.

North Harpersfield, N. Y.

Bees are booming. I never had better prospects for a good season. You can hardly imagine how happy it makes me feel, after having three very poor seasons. One colony gathered 16 lbs. July 15, and 15 lbs. July 16, and have done well ever since, also before.

A. SNYDER.

Clarksville, N. Y., July 20, 1885.

TOADS AND FROGS EATING BEES.

Do toads and frogs kill and eat bees? I notice they gather around the hive at night.

Monroe, N. C., July 16.

W. A. HAMILTON.

[Yes, friend H., toads and frogs do eat bees, as you will see by the A B C book, and that is exactly why they gather around the entrances at nightfall. If you don't take care of them they will keep your colony so weak that it will eventually run out.]

DOOLITTLE'S PLAN OF MAKING ARTIFICIAL COLONIES.

Concerning Doolittle's way of making nuclei, I have to report complete success every time, and I do not see why your correspondent Weckesser made a failure. I have written to friend D., to tell him how well I like the plan.

D. F. SAVAGE.

Casky, Ky., July 6, 1885.

ANOTHER REPORT OF FORMING NUCLEI ON THE DOOLITTLE PLAN.

I have divided one colony of bees on the Doolittle plan. I did not put them in a "mountain cave or in the cellar," but simply in a dark closet, and put in a queen which I received of you the same day that she came to hand, and an old bee-keeper pronounces it now to be a good colony.

Barton, Vermont, July 21, 1885. Mrs. J. J. HILL.

BANANAS.

In GLEANINGS for Dec. 1, 1884, you ask where bananas grow, and will probably get an answer from nearly every progressive bee-man in South Florida. Their blossoms are an admirable curiosity, as well as a prominent resort for the bees; and when not injured by freezing, they blossom and fruit the year round.

D. C. UNDERHILL.

Manatee, Fla.

TWO 3-FRAME NUCLEI INCREASE TO 12 FROM THE LAST OF APRIL UP TO THE 24TH OF JUNE.

I started with two 3-frame nuclei of Italian bees about the last of April; increased to 12 up to the 24th of June; got my start from Hemphill & Goodman, Elsberry, Mo. I am well pleased with results and prospects thus far, which are of the most flattering kind. Messrs. H. & G. got their start of Italians of A. I. Root.

JAS. A. STAFF.

Moscow Mills, Mo.

A PROSPECT OF ANOTHER GOOD REPORT FROM FRIEND MALONE.

This beats any season for honey I ever saw. I've increased from 5 to 25, and have taken 285 lbs. honey, to date; 20 are strong, and working in supers. I have not bought a bee nor queen. I have adopted a plan of my own for increase, and it works well. If this fall should prove to be as good as that of 1882, I shall have a big report to make.

WM. MALONE.

Oakley, Ia., July 18, 1885.

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

A. I. ROOT,

EDITOR AND PUBLISHER,

MEDINA, O.

TERMS: \$1.00 PER YEAR, POSTPAID.

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, AUG. 1, 1885.

And the barrel of meal wasted not, neither did the crust of oil fail, according to the word of the Lord, which he spake by Elijah.—1. KINGS 17: 16

In another column is an inquiry in regard to the practical working of the Stanley honey-extractor. The machine looks as if it would answer admirably, but we should be glad to hear from somebody who has taken a ton of honey or so with it.

DOOLITTLE'S METHOD OF MAKING ARTIFICIAL SWARMS.

A GREAT many have reported succeeding nicely by this method; and when I permitted the little poem to appear last month, I did not think of reflecting on friend Doolittle. It was a piece of pleasantry, and I thought it was rather funny, even if it was a great part of it ridiculous. Besides, the writer is entitled to a hearing, even if he does indulge in pleasantry, for he has done a "big thing" with bees and honey.

GOODS TO BE EXHIBITED AT FAIRS DURING THE COMING FALL.

For sample hives, extractors, and implements of bee culture in general, that are to be used for exhibition at fairs in a way that will probably advertise our goods, we will make a discount of one-fourth. Of course, this would apply to single samples — not to more than one of the same thing. Your simple statement, that the articles ordered are to be placed on exhibition at your county or other fair, will be all that is needed to receive this special discount.

WHERE TO KEEP VIRGIN QUEENS UNTIL THEY ARE OLD ENOUGH TO LAY.

This question comes up in my reply to friend Doolittle's article in the present number. In another column we make an extract from the *Canadian Bee Journal*, where mention is made of queens being kept confined in their cells until almost if not quite old enough to lay. If enough jelly remains in the cell to keep them the required number of days, and they do not suffer from close confinement, we are coming pretty near to the solution of the difficulty; and it comes, too, in nature's own way.

ABOUT "SENDING FOR A DOCTOR."

In my remarks last month, in the department of Our Neighbors, I did not intend to reflect upon the medical fraternity, for I well know they comprise about the most intelligent and best-posted men in community. The principal point I had in mind was that nature, if let alone, will often right many of our wrongs and ailments, and that sound common sense and reason should guide us in deciding what to do. No doubt many people have been maimed for life because they neglected to send for a doctor,

or were stubborn about it; but for all that, I believe that a great many times we call in the services of a doctor, or, worse still, take upon ourselves the responsibility of taking drugs, or "tinkering" in other ways with these bodies God has given us, when Nature would fix it if she had a fair chance, and were left alone. Of course, babies are seldom able to decide what course of treatment is best.

BE CAREFUL OF YOUR MAILING-CAGES.

ONE of the friends sends us a queen-cage which he received by mail, which should have contained samples of live Carniolan bees; but the cage was made of pine, and the hole was made so near the end of the block that a piece of the pine split out and let every bee loose into the mail-bags. He asks the question, "How many such cases as this would be necessary to again banish bees from the mails?" The point is well made. I would under no circumstances use pine for a queen-cage. It splits altogether too easily. Use basswood or whitewood, and have them made in such a way that breakage is next to impossible. We have no right to risk the loss of this great privilege to bee-keepers, by slovenly made cages.

CARNIOLAN BEES.

OUR thanks are due to several of the friends for sending us samples of the above bees. If they had been sent to me without an explanation saying that they were Carniolans, I should have decided without hesitation that they were our common bees and nothing more. Whatever good qualities they may have, there will be this objection: No one can tell whether they are pure or not, and I do not know any means of telling whether we have got one or the other. Friend Jones spoke of finding common black bees in Italy. I should say judging from the looks only that they had black bees in Carniola.

July 29.—We have to-day received two Carniolan queens from Frank Benton, with an explanation that the queens sent to other parties were ordered before ours were, and I heartily beg pardon for not having had a little more charity, which I so often recommend to others. The workers with our queens are all Italians, but the queens look more like Italian queens than they do like common black queens, though the color is perhaps rather a copper color than yellow. This will afford us at least one slight means of distinguishing the two races. The queens reached us in perfect health, and but one worker-bee was dead in the two cages. This is indeed wonderful. We notice a little improvement by putting a piece of fdn. over the apartment containing the candy. This piece of fdn. is waxed down to the wood so as to make it air-tight, thus preventing evaporation from the candy. Friend Benton stands at the head of the world in this matter of making cages to stand long journeys, and I presume he has had more experience than any other man in the world. Just as soon as eggs can be had from these queens we shall start for untested Carniolans. At present I can not say what the price will be—probably about the same that others charge. Neither can I say how soon we shall be ready to ship them, but we will fill all orders in rotation. Of course, they will be crossed by Italians.

USING A BEE-TENT TO STOP ROBBERING.

LAST Sunday morning was somewhat wet and rainy; but for all the wet, the bees seemed starting off with quite a roar, which I at first thought must

be the remnants of basswood-bloom. Pretty soon, however, I decided the roar was on too high a key; and by the time I saw a few bees hanging about the ventilators of the chaff hives, I concluded it was robbing somewhere. I passed one apiary after another, glancing up the avenues of grapevines (which are now quite bushy, and are about six feet high or more). "Oh, yes! here they are." It was one of the last artificial colonies made, and all about it was a perfect hubbub of activity, while the other 300 or 400 colonies were comparatively still. The apiarist Mr. K., soon got a bee-tent, by my instruction, and placed over the hive. He remarked that it had a hole in the top, but I told him I guessed it would do no harm. The robbers collected in large numbers in the top of the tent. As soon as they found the hole they buzzed out and started homeward rejoicing over their heavy load of ill-gotten gains. The point was, did they take their point to come back and get in at this hole? I told Mr. K. what had been reported in the journal, that a tent was better with such a hole in it, and we found that it worked all right. Of course the great body of bees came back and besieged every hive in that vicinity, but not a bee had sense enough to go to the top of the tent and crawl in that hole out of which the robbers were coming. After they had satisfied themselves that no more plunder was to be had, either by *hook* or *crook*, they one after another went quietly back to their homes; and when I came home from meeting, there stood the tent without a robber-bee inside of it, for they all got out at the hole in the top; and neither was there a robber-bee outside of it, or anywhere about the apiary. All you have to do is to put such a tent over the bees being robbed, and go back about your other work. No bees will buzz their wings off inside of the tent, or die of suffocation.

We have to-day, July 31, 6581 subscribers.

LOOK HERE!

To introduce my strain of pure bright Italians, equal to any in the United States, I will offer for August, tested queens, \$1.00 each; extra fine, selected, \$1.50 each; one-frame nucleus, consisting of one extra selected queen, one frame of brood, ½ lb. bees, for \$2.00. If you want any bees, send me your address on postal and I will send you sample by return mail. Beeswax or honey taken in exchange.

15tdb **THOMAS HORN,**
Box 691, Sherburne, Chen. Co., N. Y.

WARRANT FREE

On dollar queens in August and September. There is not a black or hybrid stock near my apiary. Take notice thereof, and govern yourself accordingly.

15d **J. B. HAINS, Bedford, Cuy. Co., O.**

\$2.50. Cheap! Cheap! Cheap! \$2.50

During August and September I will sell at the following low prices, one untested queen, reared from imported or home-bred Italian queen-mother, 1 lb. pure Italian bees, two Simplicity frames filled with brood and honey, all worker comb, in three-frame nucleus hive, all in good shape, and worth \$4.00 for only \$2.50. This adv. will not appear again, so remember it! Make money orders payable at Sherwood, O.

15d **F. W. MOYER,**
The Bend, Defiance Co., Ohio.

PURE ITALIAN QUEENS. 100 READY EVERY 30 DAYS.

Untested at 75 cents; 10 for \$7.00. Tested queens, \$1.50 each. All bred from a selected imported mother. Cells raised in full colonies.

12-16d **D. G. EDMISTON, ADRIAN, LEN. CO., MICH.**

SECOND-HAND FOOT-POWER SAWS.

We have, subject to our order, three Barnes foot-power buzz saws, which we have taken from parties whose business has enlarged so much that they have no further use for them. They are all nearly new, in good order, having all the latest improvements. We will sell them for one-fourth less than the regular retail price; that is, we will sell a \$40.00 saw for \$30.00.

A. I. ROOT, Medina, O.

12 STRONG HYVS of 16 to 20 L. combs, Italian bees for sale at \$4.00 \$5 per colony. 15d
A. B. WEED, 110 WINDER ST., DETROIT, MICH.

1000 POUNDS OF BEES FOR SALE,
Italians and Hybrids, at 75 cents per pound, safe arrival guaranteed.
R. L. TAYLOR,
LAPEER, LAPEER CO., MICH.

EXCHANGE DEPARTMENT.

Notices will be inserted under this head at one-half our usual rates. All ads. intended for this department must not exceed 5 lines, and you must say you want your ad. in this department, or we will not be responsible for any error.

WANTED.—To exchange Chaff and Simplicity hives, wood brood and wide frames, sections in flat, or set up, at A. I. Root's lowest prices, guaranteed as well made, and as good material, for new extracted clover or basswood honey at 9 cts. per lb. 15d
J. B. McCORMICK, Fredericksburg, Wayne Co., O.

WANTED.—To exchange three-band Italian bees for one dozen Brown Leghorn chickens. 15d
JOHN NORRIS, Manchester, Adams Co., Ohio.

WANTED.—To exchange a new circular saw machine for hive-making, worth \$25.00, for extracted honey. Address 15tdfb
D. S. HALL, So. Cabot, Vt.

WANTED.—If you have any thing you want to exchange for pure Italian bees, send me a description of it. 15d
THOMAS HORN, Sherburne, Chen. Co., N. Y.

WANTED immediately.—To exchange Italian bees for foundation to use in L. brood-frames. 15d
O. H. TOWNSEND, Alamo, Kal. Co., Mich.

Black and Hybrid Queens For Sale.

I have some black queens for sale at 25 cts. each. 15d
IRA D. GRANGER, Madison, Lake Co., Ohio.

I will sell in August, 18 prolific hybrid queens at 25 cts. each, all raised from natural swarming. 15d
W. A. SANDERS, Oak Bower, Hart Co., Ga.

A few extra fine hybrid queens for sale. They are very prolific, and a bargain. Price 40c; or if you return cage, 35c. 15d
E. H. COOK, Andover, Conn.

We have a few black queens; some of them probably mated with Italian drones. Price 25 cts. each. 15d
KELLOGG & SONS, Prairie Center, La Salle Co., Ill.

I have a few hybrid queens producing yellow-banded bees, at 30c each. Very dark untested, but laying queens, and some fair in color, but producing very dark bees, 20c each. 15d
J. S. HOFFMAN,
253 Hepburn St., Williamsport, Pa.

Two hybrid queens for sale at 25 cts. each, and two or three untested Italians at 50 cts. each. None but Italian drones in apiary. 15d
J. T. GODDARD,
Box 482, Muscatine, Iowa.

I have 6 or 8 hybrid queens for sale at 60c each; two have clipped wings, are one year old, and are almost pure Italians. The others are untested, but are laying, and may or may not prove to be purely mated. All are ready now. Safe arrival guaranteed. 15d
GEOR. P. KIME,
Evansburgh, Coshocton Co., Ohio.

Names of responsible parties will be inserted in any of the following departments, at a uniform price of 20 cents each insertion, or \$2.00 per year.

\$1.00 Queens.

Names inserted in this department the first time without charge. After, 20c each insertion, or \$2.00 per year.

Those whose names appear below agree to furnish Italian queens for \$1.00 each, under the following conditions: No guarantee is to be assumed of purity, or anything of the kind, only that the queen be reared from a choice, pure mother, and had commenced to lay when they were shipped. They also agree to return the money at any time when customers become impatient of such delay as may be unavoidable.

Bear in mind, that he who sends the best queens, put up most neatly and most securely, will probably receive the most orders. Special rates for warranted and tested queens, furnished on application to any of the parties. Names with *, use an imported queen-mother. If the queen arrives dead, notify us and we will send you another. Probably none will be sent for \$1.00 before July 1st, or after Nov. If wanted sooner, or later, see rates in price list.

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they want to dispose of, we will insert notices free of charge, as below. We do this because there is hardly value enough to these queens to pay for buying them up and keeping them in stock, and yet it is oftentimes quite an accommodation to those who can not afford higher priced ones.

I have 5 Italian hybrid queens at 30 cents each.
N. A. KNAPP, Rochester Depot, Lorain Co., O.

Hybrid queens from Sunny-Eden apiary, 50c. each. Safe arrival guaranteed.

W. S. DORMAN, Mechanicsville, Cedar Co., Ia.

Good hybrid queens, 50 cts. each, from August first to November first. Safe arrival guaranteed.
MOSES BRECHBIEL, Newburg, Cumb. Co., Pa.

A few black queens for sale at 25 cts. each. Safe delivery guaranteed, or money refunded.

L. C. CALVERT, Poplar Flat, Lewis Co., Ky.

Hybrid queens, 50 cts. each; black queens, 25 cts. each, from Aug. 1 to Oct. 1. Safe arrival guaranteed.
G. D. RAUBENBUSH, Reading, Berks Co., Pa.

One black queen, one year old, 15c. Four hybrid queens, six weeks old, 30c. each. Nice yellow untested Italian queens, just commenced to lay, 60c. each. J. H. JOHNSON, Middaghs, Northam. Co., Pa.

One-half dozen hybrid queens for sale. Will be shipped in the *Safe* introducing cage, for 50 cents each. All young and prolific.
S. A. DYKE & Co., Pomeroy, Ohio.

I have one dozen black queens at 25c., and 4 hybrid at 50c. The mother of the hybrids is one that I bought of A. I. Root last month—one of his best imported Italian queens.

R. B. BONEAR, Cherry Ridge, Pa.

I am raising hybrid queens from my best honey-gatherers, and will sell them at 50 cts. each. I consider them better than my Italians, except in docility.
E. C. EAGLEFIELD, 100-119, Poy Sippi, Waushara Co., Wis.

Having some 12 or 15 hybrid queens on hand, I will send them to any one, one or more for 50 cts. per piece. They are daughters of imported Italian queens, reared in May and June, this year. Sent by mail in Peet cages. Postage-stamps accepted.
JOHN A. THORNTON, Lima, Ill.

I shall throw out several dark and small (but prolific) Italians, and a number of hybrid queens, in getting away with the hybrids in this locality, and shall sort them according to their merits, at 15, 25, 35, and 45 cents apiece.
C. WECKESSER, Marshallville, Wayne Co., O.

I have six black and twenty hybrid queens. Blacks, this year's queens, each, 25c., last year's 20c.; hybrids, this year's 50c., last year's 40c. I will take $\frac{1}{4}$ less for the lot, if taken at one time, and provisioned cages are sent.

J. A. BUCKLEW, Clarks, Cosh. Co., O.

I have two fine young hybrid queens reared from a pure Italian mother. They are very prolific, and their progeny not very cross. Have they any value at all to you? I hate to kill them. I will sell them to you or any one else at your own price.
S. H. HICKOK, Bethel, Conn.

AFTER AUGUST 1ST, I WILL SELL

Bees as follows: 2-frame nuclei, \$2.00; 3-frame, \$2.40; full colony in Root's Simplicity hive, \$6.50. Each of above to contain 1st's queen, \$1.00 queen, 75c.; tested, \$1.25. Some fine Poland-China pigs, very cheap. Address N. A. KNAPP, ROCHESTER, LORAIN CO., O.

20 COLONIES ITALIAN BEES AT \$4.50 EACH.
15-18d M. ISBELL, Norwich, N. Y.

DADANT'S FOUNDATION FACTORY, WHOLESALE AND RETAIL. See advertisement in another column.

DADANT'S FOUNDATION

is asserted by hundreds of practical and disinterested bee-keepers to be the cleanest, brightest, quickest accepted by bees, least apt to sag, most regular in color, evenest, and neatest, of any that is made.

It is kept for sale by Messrs. A. H. Newman, Chicago, Ill.; C. F. Muth, Cincinnati, O.; Jas. Heddon, Dowagiac, Mich.; Dougherty & McKee, Indianapolis, Ind.; Chas. H. Green, Berlin, Wis.; Chas. Hertel, Jr., Freeburg, Ill.; Ezra Baer, Dixon, Lee Co., Ill.; E. S. Armstrong, Jerseyville, Ill.; H. Drum, Adelphi, O.; Arthur Todd, Germantown, Philadelphia, Pa.; E. Kretschmer, Coburg, Iowa; E. F. FOR SALE.

21 Colonies of Pure Italian Bees in Langstroth frames, straight pretty combs, with honey, in DOUBLE-WALL OBSERVATORY HIVES; Been used two seasons with one-pound boxes, and for extracting. Complete on board cars, for \$8.00 per colony, or \$14.00 for the lot.

JAMES CRAIG,

16 E. 18d

MT. MERIDIAN, VA.

DADANT'S FOUNDATION FACTORY, WHOLESALE AND RETAIL. See advertisement in another column.

CARNIOLAN QUEENS.

After August 15, I think, I shall be able to send queens by return mail. They are daughters of an imported queen, but fertilized in my apiary of 60 colonies of Italians. My Carniolan bees are easily distinguished from native bees by their appearance alone, and they are quieter and much less inclined to sting than the gentlest bees of any other race I have seen. Sample Carniolan bees, free, postpaid. Carniolan queens, safe arrival guaranteed by mail, one dollar each.

16ftdb

JAMES H. MORRISON,

OXFORD, CHESTER CO., PA.

W. J. ELLISON,
STATEBURG, SUMTER CO., S. C.

Has a lot of fine Italian queens raised from splendid stock, that he will sell at \$1.00 each; \$9.00 per dozen, or \$65.00 per hundred. Safe arrival guaranteed. 16 E 1d

NUCLEUS.—I have 50 two-frame nuclei, strong in bees, with fine Italian queen. I will sell for \$2.50 each. By adding frames of brood or empty comb these nuclei can be built up to strong colonies for winter.

16d

T. S. SANFORD,

Box 584,

Bradford, Pa.

TO CLOSE OUT.

I will sell 12 chaff hives, made up and painted, at \$1.09 each. Also three colonies Italian bees at \$3.00 per colony. W. K. LEWIS, DRY RIDGE, KY. 16d

Queen-Rearing.

How to rear queens by the best and simplest methods. For particulars address

JOB LOT OF WIRE CLOTH

AT GREATLY REDUCED PRICES.

SECOND QUALITY WIRE CLOTH AT 1½ CTS. PER SQUARE FT.

SOME OF THE USES TO WHICH THIS WIRE CLOTH CAN BE APPLIED.

This wire cloth is second quality. It will answer nicely for covering doors and windows, to keep out flies, for covering bee-hives and cages for shipping bees, making sieves for sifting seeds, etc.

Number of Square Feet contained in each Roll Respectively.

Inches Wide.	No. of Rolls.	Number of Square Feet contained in each Roll Respectively.

FIRST QUALITY WIRE CLOTH AT 1½ CTS. PER SQUARE FT.

The following is first quality, and is worth 1½ cts. per square foot. It can be used for any purpose for which wire cloth is ordinarily used; and even at 1½ cts. per sq. ft. it is far below the prices usually charged at hardware and furnishing stores, as you will ascertain by making inquiry. We were able to secure this very low price by buying a quantity of over one thousand dollars' worth.

HONEY COLUMN.

CITY MARKETS.

KANSAS CITY.—*Honey.*—Trade in this article very quiet just now, mostly extracted in bulk and our small glasses and tins, moving at this time of the year. We have made some large sales of extracted honey this week. Southern, 50¢c; clover and sage, 60¢c. Comb honey nominal at 12@13¢ for choice 2-lb. sections; 13@14¢ for 1-lb. *Beeswar.* weak, 20@25¢.

CLEMONS, CLOON & CO.,

Cor. Fourth & Walnut Sts., Kansas City, Mo.

Aug. 6, 1885.

ST. LOUIS.—*Honey.*—The warm weather continues to depress our honey market. Extracted in barrels, Southern, old, 36@37¢c; new, 40@41¢c, nominal. In cans, retail, Northern white clover, 9@10¢. Comb honey, old, not salable; very little new in market. We look for an improvement in a few weeks. *Beeswar.*, 22@23¢.

W. T. ANDERSON & CO.,

104 N. Third St., St. Louis, Mo.

Aug. 10, 1885.

CHICAGO.—*Honey.*—The new crop is coming in to a fair degree, and the demand is about equal to the receipts. It brings 15¢ per lb. for 1-lb. sections; little else coming. Extracted honey, 5@7¢c; demand better. *Beeswar.*, 22¢.

R. A. BURNETT,

161 So. Water St., Chicago, Ill.

Aug. 11, 1885.

CLEVELAND.—*Honey.*—New honey has made its appearance, and is selling in 1-lb. sections at 15@16¢. Old honey stands still, there being no demand for it; still, we are willing to sell it at 11@12¢. *Beeswar.*, 22¢.

A. C. KENDEL,

115 Ontario St., Cleveland, O.

Aug. 12, 1885.

CINCINNATI.—*Honey.*—No change whatever since my last. Market dull for all kinds, with large arrivals. *Beeswar.*, no change; arrivals and demand fair. It brings 20@22¢ on arrival.

CHAS. F. MUTH,

S. E. Cor. Freeman and Central Avenues,
Cincinnati, O.

Aug. 11, 1885.

DETROIT.—*Honey.*—The honey market is still very dull. One-pound sections are selling at 10@12¢.

Aug. 12, 1885.

A. B. WEED,

407 Woodward Ave., Detroit, Mich.

HONEY AND BEESWAX.

We are now in the market, and will be during the entire season, for all honey offered us, in any quantity, shape, or condition, just so it is pure. We will sell on commission, charging 5 per cent; or if a sample is sent us, we will make the best cash offer the general market will afford. We will handle beeswax the same way, and can furnish bee-men in quantities, crude or refined, at lowest market prices. Our junior member in this department, Mr. Jerome Twichell, has full charge, which insures prompt and careful attention in all its details.

Sample of comb honey must be a full case, representing a fair average of the lot. On such sample we will make prompt returns, whether we buy or not.

CLEMONS, CLOON & CO.,

Wanted. Situation in California

By a young married man, who wants to try California before locating; has had 15 years' experience with bees, has 250 stands; is a carpenter and builder, will work at any thing during winter; would like to come in December. How much am I offered? 16d F. J. FARR, Buckner, Mo.

HUTCHINSON'S

ADVERTISEMENT.

We are now making a specialty of rearing fine Italian queens. All queens are bred from the purest and best of mothers, and the cells built in full colonies. We have one of A. I. Root's very best, selected, tested, imported queens, also quite a number of very superior home-bred queens from the apiary of "Cyula Linswik." Besides this we have our own original stock which was built up from Dadant imported stock and from queens obtained from several of our best breeders. We are not trying to see how cheaply we can rear queens, but how good ones we can furnish. No queens will be sent out that would not be used in the home apiary. Single queen, \$1.00; six for \$5.00; twelve or more, 75 cts. each. Tested queens, \$2.00 each. Full colonies, \$5.00 each. Make money orders payable at Flint. Address

EXCHANGE DEPARTMENT.

Notices will be inserted under this head at one-half our usual rates. All ads intended for this department must not exceed 5 lines, and you must say you want your ad in this department, or we will not be responsible for any error.

WANTED.—Comb and extracted honey, and wax, in exchange for Italian bees, queens, foundation, or fdn. machinery. Also two foot-power-saw mandrels with 5 and 6 in. saws. See circular, and state particulars.

16d OLIVER FOSTER, Mt. Vernon, Linn Co., Iowa.

WANTED.—To exchange bees in L. hive for thoroughbred poultry.

16-17d B. J. PURCELL, Concord, Ky.

WANTED.—In exchange for new varieties of strawberries and raspberries, Plymouth Rocks, Light Brahmas, Pekin Ducks, new varieties of potatoes, and small-fruit plants, cherry and quince trees.

P. SUTTON, Exeter, Luz. Co., Pa. 16-23db

WANTED.—To exchange Zimmerman Fruit-Evaporator, and 100-egg incubator, both new, for good section and extracted honey. Will give you a bargain now.

16d KANAWHA-VALLEY APIARY, St. Albans, W. Va.

WANTED.—To exchange a new circular-saw machine for hive-making, worth \$25.00, for extracted honey. Address

15fdb D. S. HALL, So. Cabot, Vt.

WANTED.—To exchange salt mackerel on 10-lb. pails, for good extracted honey.

16d E. E. LING, 11 Silver St., Portland, Maine.

WANTED.—To exchange Italian bees for beeswax: 20 lbs. wax for a colony.

16fdb M. ISBELL, Norwich, N. Y.

WANTED.—To exchange a 50-inch Standard Columbia bicycle, in good order, for honey (comb honey preferred); will take part money to suit the purchaser. Correspondence solicited.

F. E. EDWARDS, Bellows Falls,
Box 520. Windham Co., Vermont.

WANTED.—To exchange for Italian queens or cash, late spring Plymouth-Rock Cockerels. Warranted. Prices, single, \$1.50; pair, \$2.00.

A WORD TO THOSE WHO EXPECT TO BUY BEES IN THE SPRING.

WHICH IS BETTER, TO BUY NUCLEI NOW AND BUILD
THEM UP, OR PURCHASE FULL COLONIES
IN APRIL?

THE above question was propounded by a customer who called to see us yesterday. He wants to begin with bees, and has not very much capital. Now, let us see. A full colony in April, according to our price list, and, I think, according to the price list of most reliable dealers, will cost about twice what it would after the first of July. You see the price of a colony of bees runs down rapidly after the honey season is over, when no more honey is to be gathered, or, at least, not much prospect of any. Then the wintering trouble has to be faced, so that bees, just before the honey season, early in the spring, ought to be worth at least double what they are in the fall. It is true, some advertisers offer them less, but they do not often furnish full colonies. When we send out a full colony in April we take the best we have in the apiary; and if we haven't any that can be consistently called a good strong colony, we take hatching brood from one or more of the others. If we do this, of course we must have a good price. But such a colony is worth a good price, for it can be divided at once, or made to give a good crop of honey or many swarms, because it is strong even before the season opens. Our friend thought he ought to have about six colonies to begin with. Six colonies as above, with select tested queens would be worth \$156; with the discounts \$117.00 in April, 1886.

He could not afford so much money, so he, by my advice, bought six pounds of bees, with a comb of brood and a select tested queen for each pound. These cost him \$27.54, therefore he would have \$89.46 to buy sugar, and to pay him for his labor in feeding them and building them up to full colonies in time for winter. As he has plenty of time, and is anxious to learn bee culture, his experience in building them up will be worth a good deal to him, to get them ready for next season's work. Of course, he has the wintering trouble to face; but even if he loses them, the amount invested is not very large after all; and if he takes right hold of it, and does his duty, I think there can be little question but that they will winter. As he is in a locality where there is little chance for fall honey, his built-up colonies will have stores of granulated sugar; and if put in chaff hives, I think there is little doubt but that they will winter safely—at least, reports from colonies built up in this way have always been favorable. As our friend knows comparatively little about bees, I told him that he had better get some experienced bee-man near him to take a look at his nuclei occasionally, to see if they are building up as they ought to do. He chose select tested queens, because we have tested these for prolificness, and any one of them would fill a hive with brood very speedily.

Of course, he must have six hives for his bees, and he also wants some combs of foundation. This will make somewhat of an additional expense. He might have saved a little expense by taking untested queens instead of select tested, and I think I would, as a general thing, advise the untested. The

expense of making the experiment is then comparatively trifling. If he succeeds in building his nuclei up to good strong colonies, and winters them, he will probably make a profitable investment of it next year. If he is not calculated for a bee-man he will probably lose them all during the winter, and become disgusted with the business, without being very much out of pocket. The question is, Will a pound of bees, and a frame of brood and a queen, started, say, in the middle of August, build up so as to make what may be called a fair colony by the middle of November? We could do it easily here; but whether the average novice would succeed in doing it, is another question. I advised him to use the Simplicity feeder, because this will hold all a pound of bees will need at a time, and the expense is trifling.

Very likely many of you can buy cheaper than at the prices I have given. In fact, nuclei are advertised in this number, cheaper than we sell them; and if you wish to purchase, I would advise you by all means to buy of somebody near your home, to save the expense of express charges. If you can go and get them with a horse and spring wagon, all the better. I do not know of any work I ever enjoyed more than building up nuclei in the fall into full colonies, in this way. I would keep up the feeding until the weather gets too cold for the bees to take it from the Simplicity feeder; and then if they have not an abundance of stores to go into winter, I would commence feeding again in the spring, as soon as it is warm enough for them to go back to the feeder again. As the weather becomes cool, I would cover the brood-nest, all except a little opening right over the cluster, and I would set the Simplicity feeder right beside this opening. If this opening is small, say half an inch in diameter, it will do no harm if left open all winter. Such openings had better always be left, unless the covering to the bees is some coarse material, such as burlap or sacking.

I should very much like to hear reports from those who undertake this matter of building up nuclei, so that we may determine for future seasons how late it will be safe to attempt it. Of course, much depends on the laying powers of the queen, and the way in which the bees go to work to help her. The pound of bees ought to be young ones.

MRS. CHADDOCK'S LETTER.

She Tells Us how to Make Beeswax out of Doors.

ALSO SOMETHING ABOUT A BEE-MAN WHO MAKES MONEY.

LAST Monday I spent a pleasant hour with Mr. Rufus Porter, of Lewistown, Ill., and his most estimable wife. Mr. Porter has been for many years a successful bee-keeper; but he is not doing anything with them now, his son having the entire control of them. Mr. P. has about 75 colonies at present, in Langstroth hives, and he runs them altogether for extracted honey. He ships all his honey, and pays no attention to his

home market; he winters successfully, and he knows how to render beeswax. He told me how his bees were prepared for winter. In September, or early in October, he takes off the honey-apartment, and places a few corn-cobs, or a little frame made on purpose, over the brood-nest, and then he puts on a frame made to fit the top of the hive and to go inside the cap, with a piece of coarse coffee-sack nailed across the bottom of it. This frame is filled with wheat chaff thrown loosely in, and not packed down at all. His bees face to the south, have no shade over them, and he lets them severely alone. After he had said a good many other things, he said, "Now I want you to take something back. I'll tell you how I extract beeswax, and I want you to promise to try my way."

"Oh!" said I, "you have a wax-extractor."

"Well, yes," said he; "I have one; I paid six dollars for it, but I do not use it. I have a big iron kettle sitting away back in the yard on some stones, and when I have some wax to render out I build a fire under the kettle, fill it nearly full of water, and after it comes to a boil I dump in part of the old combs; and as the wax rises to the top I dip it off and pour it through a sieve, made of mosquito netting, nailed to a frame—this frame, or sieve, being placed over an old tub, or half a salt-barrel will do, with cold water in it. When I have dipped off all the wax that rises from what I first put in, I put in another batch, and dip off again, not letting the water boil, but just keeping it boiling hot. After I am through with melting I take the wax out of the cold water and heat it so that it will run, and make it into any shape that I want it. Now I want you," said he, "to try my way, and report on it. You can burn the half-barrel and the sieve when you get through, and there will not be many things to clean up. Now, will you try this way?"

I said, "May be."

In 1871 Mr. Porter made \$1200, *clear money*, from one hundred colonies of bees (spring count, I believe). But this is no sign that others can do it. Mr. Porter being one of those who have the touch of Midas (was it Midas? If not, it was somebody else, who turned every thing he touched into gold). Any way, he knows how to get money out of every thing that he undertakes. He was engaged for a number of years in the small-fruit business, and he made money at that. Now he is running a drain-tile factory, and all of you who live on low land know that there is money in drain tile.

MAHALA B. CHADDOCK.

Vermont, Ill., Aug., 1885.

Mrs. C., friend Porter's plan might please some of the friends, under some circumstances; but it seems to me as if it would be also wasteful. He had better buy a sort of press to squeeze the wax out of the residue; and it seems to me that, in burning up the barrel and sieve, that is rather wasteful too, because a good deal of wax will be adhering to them, unless you clean it off with boiling water or steam. We do not like to waste even a barrel on our premises. It has one merit, however—it gets unsightly things out of sight, unless you should call the old kettle unsightly; but I suppose that might be kept back of the barn or hog-pen. You know I think it is a grand thing to keep the front yard looking tidy, even if you can not have all the premises so.

FALSE STATEMENTS IN REGARD TO THE HONEY BUSINESS OF OUR COUNTRY.

As a protection to our bee-keeping population, we propose in this department to publish the names of newspapers that persist in publishing false statements in regard to the purity of honey which we as bee-keepers put on the market.

WE are pleased to notice some kind words from the *Prairie Farmer*, in regard to the way in which bee-keepers have been wronged by newspaper stories about the adulteration of honey. It is pleasant to know that at least one of our agricultural papers feels like helping to right so great a wrong.

One of our correspondents sends us the following clipping from the *Anaheim, Cal., Gazette* of July 18:

The Massachusetts State Board of Health, from recent investigation, finds that there is very little pure honey in the State. That sold in little glass jars is not honey at all, but simply glucose, with just a little of the honeycomb put in.

The above has been going the rounds for some little time, and we should like to have the matter investigated. In the first place, what is the Massachusetts State Board of Health? Can any of our friends who live in the above State tell us about it? Next, is it true that the honey offered for sale in the provision stores of Massachusetts is, very little of it, pure honey? Will the bee-keepers of that State please look into the matter? It seems to me it is a gross misrepresentation. If it is indeed true, that Massachusetts is flooded with spurious honey, then the bee-keepers of the State, assisted by the bee-keepers of other States, if need be, should look to it that good pure honey be offered at a reasonable price by all who make it their business to deal in honey. We shall be very glad indeed of help to get more facts in the matter. Each State in the Union has a duty to perform in this matter. Who will help to remove this stigma from the bee-keepers of Massachusetts?

BEES AND FRUIT.

I inclose you a new remedy for killing bees when troublesome to fruit, which you will please insert in *GLEANINGS*, for the amusement of our bee-keeping friends. It is taken from our local paper, and is the funniest thing relating to bees which I have ever read. Oh how it made me laugh when I read it! I want to add, that "many fruit-growers" don't adopt the "ingenious and efficacious" plan, or else what a glorious time the bees would have!

The irrepressible conflict between the fruit-grower and the bee-keeper is again to the fore. Though grapes are not ripe, the bees are busily at work harvesting them, to the annoyance and loss of the vineyardists; and unless the owners of the depredated bees corral them, we are requested to give warning that the bees will be warred upon.

The ingenious and efficacious way of killing bees which many fruit-growers here adopt is to attract the bees to vessels of honey on which common flour has been sprinkled. This flour adheres to the feet of the bees, and is thus carried to the hive, where it ferments and asphyxiates the inmates.

—*Anaheim Gazette*, July 18, 1885.

Now, I want to ask a question. Suppose bees take a load of some liquid or fruit-juice that has been poisoned with strychnine or arsenic, will it kill them before they are able to store it in the hives, or can

they carry it in and store it in sufficient quantities to hurt human beings, if eaten?

1—ALFRED W. HIND, 16—21.

Anaheim, Cal., July 29, 1885.

Friend H., no doubt the extract you send us will provoke a smile from many bee-keepers, and yet there is something sad about it to me, to think that we must have difficulty and disagreement.—Bees will usually die before they get to the hive, when poisoned with Paris green or other arsenical preparations; but I should think it quite probable that, when the distance is short, they might carry enough into the hives to make the honey dangerous for people to eat.

A BEE-CONVENTION IN SYRIA.

AN INTERESTING LETTER FROM FRANK BENTON, IN REGARD TO APICULTURE IN PALESTINE.

WE had a bee-convention in Syria; or, rather, we've been having a series of them here recently. This may seem rather surprising news to people of the Western World, who suppose Syria is beyond the pale of civilization. But though the country is in many respects behind Europe and America, modern methods in bee culture have now taken permanent root here. The gatherings have been quite informal in their nature, as close application of parliamentary rules in the conduct of such meetings is not the way of the country; moreover, of the seven or eight different languages represented by the members of the convention, four had to be employed in the talks on bees; namely, English, French, German, and Arabic. Perhaps some of the friends in other countries, who find with but one official language in their conventions it is still difficult to get on harmoniously, will wonder what we could do with such a Babel of tongues. Nevertheless we got on quite well, and the interchange of ideas will no doubt prove of great value to many of the participants. At one of the meetings a president was unanimously elected, but he hasn't yet called anybody to order. Probably the most important work done by the convention was the adoption of a standard frame for Syria, to be known as "the Syrian Standard Reversible Frame." All bee-keepers in countries where several sizes of frames have come into use will comprehend at once the wisdom of such a step while movable-comb bee-keeping is yet in its infancy in these parts. The frame adopted measures 14 $\frac{1}{2}$ inches (= 365 mm.) in length, and 8 $\frac{1}{4}$ inches (= 213 mm.) in depth. All members of the convention, which included two Americans, one Frenchman, one German, one Italian, and a number of Syrians, follow American methods altogether in their apiaries, if we except one, a Syrian peasant who has but one frame hive as yet, and for the present retains native hives—long cylinders made of clay or of wicker-work, and also earthen water-jars, into both sorts of which the bees are put after the receptacle has been laid on its side.

Among other topics which were discussed at our meetings, migratory bee-keeping (already largely practiced here) and hives adapted to it received much attention; also in connection with this the various bee-ranges of the country were discussed. Orange-blossoms furnish the chief spring harvest, though almond, apricot, and other fruit-blossoms,

are of importance. Cactus-plants supplement these; in fact, in many localities they form the chief early honey-yield. The late harvest comes in midsummer from wild thyme, which is abundant in most of the hilly and mountainous portions of the country. Of course, there are also many minor sources,—wild flowers, etc. It was agreed, that where orange, cactus, and thyme blossoms were abundant, with the usual minor yields, nothing would be gained by transporting bees to other pastures.

The wintering problem didn't get much attention, since there is no difficulty on that score here; nor did we devote very much time to a discussion of the relative merits of the different races of bees, as none but Syrians are kept in Syria. The writer, however, and a member formerly in his employ in Cyprus, testified to the superiority of the Cyprians over the Syrians. No other members had had any experience with Cyprians.

Altogether, a bee-convention in Syria may be considered an interesting and important event — interesting to the outside world as showing the progress already made, and that America has been taken as the model; important to the country itself, both because it is likely to spread greater interest in an industry which can be made to contribute much more than heretofore to the welfare of Syria, and because the proceedings are likely to induce a more systematic development of the industry in the East.

The convention adjourned to a photographer's, and the migratory shadows were committed to paper. As far as means will permit, copies of the same will be sent to the bee-journals.

Friend Root, of GLEANINGS, will surely take kindly to our President, who appears in the center of the group with his hand resting on the A B C book. French bee-keepers will not be ashamed of their countryman, Mr. Philip Baldensperger, whose large honey-yields in Palestine have attracted attention, but which have unfortunately been attributed to German methods and even to German bee-keepers, by parties who knew better.* Messrs. Dennler & Zwilling, of Alsace-Lorraine, will recognize in his hand a copy of their journal. It so happens that this disciple of American bee culture is flanked by Americans; for your humble servant, to whom the penning of these chronicles seems by common consent to have been left, stands at his other hand. The little block of wood with three holes in it, and the reversible frame with no attachments or projecting corners, will be recognized by some, any way. A man of Italian origin stands at my left. He has never owned any bees, but was in my employ some time; in fact, I might say he has been my *left-hand man* for two or three years past. Still further to the left, a Syrian schoolmaster, owner of ten hives, holds in his hand a copy of the *British Bee Journal*; yet though he knows English and French, he is not a subscriber to nor a reader of any bee-journal, nor has he ever owned or read a book on bees. Perhaps this Syrian friend prefers the *name* and not the *thing*. In front of him is a Syrian merchant — a former landlord of mine. The good-looking full-bearded man who stands at the left in the picture represents the sturdy German race, and says he is "strongly interested in bees." Next to him is a peasant friend with his daughter. The lat-

ter, who holds an earthen jar such as the peasants employ as hives, has had much to do with recent work in bee culture here; for on a tray placed on her head she has brought down from distant villages of Mt. Lebanon, in twos, many of the stocks of bees that have furnished the queens for customers in far-off Europe and America. The juveniles are represented by two rising bee-keepers, one of whom has evidently adopted the smoker, while the other has "sat down" on the native cylinder hive.

Our eyes are turned toward America for light in bee-keeping matters; and if the world hears of large reports from these shores of the Mediterranean, the credit of them will, it is to be hoped, go where it belongs.

FRANK BENTON.

Mt. Lebanon Apiary,

Beyrout, Syria, May, 1885.

Friend Benton, we are exceedingly obliged to you for your picture, and the very graphic description you have given of it. We are very glad indeed to be able to look upon the countenances of our far-away friends and comrades: and with what alacrity would we extend the hand of fellowship, had we the opportunity of mixing in with your little group! Please tender them all our kindest wishes, and tell them that it will afford us the utmost pleasure to assist them in any way in getting the "hang" of modern bee culture, as it is now practiced here in America. But, look 'e here, old friend, I do not know whether we had better claim to be in advance of you away off there in Syria or not, while you hold that reversible frame in your hand—that frame "without any corners or projections," as you express it. You know I said in an editorial a year or more ago, that the thought of such a frame kept haunting me. When I was half asleep at night, some phantom would hold it out to me, and I would jump and grasp for it; but when I got it, and began to think it over, I could not discover any practical way of using it, without hitching something on to the corners, like our reversing wires for instance. I suppose you mean that the frame that you hold belongs in that hive in front of you, where we see the vacant place. Now, will you be so kind as to tell us what holds it in place after you put it in? What keeps it from pushing over against its neighbors, or from mashing bees against the end of the hive, and at the same time gives a lateral movement endwise and sidewise, that we have almost all decided we must have, from good old father Langstroth down? If you have something that you can work with in that way, please out with it, and don't keep us in suspense.—Are you not a little severe on our friends Howard and Alley? I have not looked up the reference, but I feel quite sure that our good friend Howard, who made us a call about a year ago, did not mean to misrepresent in any way. It is true, that the Palestine queens that he brought us have not turned out very well, for we have only one of them left, and that one produces such small cross bees, and not extra honey-gatherers either, that we do not dare offer for sale any queens reared from her; but for all that, I am sure that friend Howard supposed he was doing us a favor when he brought us the queens.

* See Howard's and Alley's reports in GLEANINGS and the A. B. J.; also see editorial notes in the *Bienen-Zuechter* of Alsace-Lorraine.—F. B.

OUR FRIEND FRANK BENTON AND HIS FELLOW-KEEPING COMRADES IN BEYROUT, SYRIA.
A Free-Keepers' Convention with the Representatives of eight different languages present.

WINTERING WITH STORES ALWAYS ABOVE THE CLUSTER.

Report from Bee-Friends who keep from 400 to 500 Colonies in Six different Apiaries.

IN TWO CHAPTERS.

NOW that the fruit-trees are in full blossom, we think we can make our report and give our true standing in regard to loss of bees for the winter and spring. We went into winter quarters with 465 colonies of bees. To-day we count up 324, and we don't think we shall lose any more. This has been a very hard winter, and everybody's pet theory has been put to the test. For our part we have no pet theory further than this: When we lose a colony of bees we try to find out why they died. We have not lost a colony but that, on opening up the hive, the reason of the loss is plain enough to be seen. And just here I would say, we don't go a cent on the pollen theory or sugar stores either. We never take away any pollen, and have never fed a pound of sugar to our bees, but still we have been moderately successful with our bees; and even this very hard winter we are still 38 colonies ahead of last year, and all were wintered on their summer stands.

We keep our bees in six places—one yard at home, and the other five apiaries from four to nine miles away. We hire help during the extracting season only. All board at our house, and go with teams to the different yards, and extract one yard a day, and there is no one to look after the bees when we are away.

We raise but very little comb honey, and that at the home yard; we keep our queens all clipped.

But, why did we lose so many bees? Well, there are several direct and indirect causes. In the first place, I will say that all that died during the winter, starved—starved with plenty of honey in the hive; but the very cold weather prevented them from getting it. They ate their way up to the top of the frames. It was too cold to move to where they could get honey. Then they had the dysentery, and died. What gave them the dysentery? Perhaps it was pollen. But, why did they eat the pollen? Because they got out of honey. Now, I take the ground that, if they had honey directly over the cluster, they would have been all right; they would not eat pollen enough to hurt them. At any rate, we have not had one case of dysentery nor lost a colony of bees that had honey over the cluster—not a comb soiled, bees strong and healthy; on the other hand, when the bees ate all the honey over the cluster, clear up the top, they all had the dysentery; and what did not die right out dwindled badly—some deserted this spring.

We claim that the kind of hive used has a great deal to do with wintering bees successfully. We have been using three different frames and hives; but what we like best is a quadruple hive, double-walled, two inches of chaff all around, holding four colonies of bees, all under one roof. Each division of the hive is $13\frac{1}{2} \times 13\frac{1}{2} \times 21$ inches high, inside measure. We use 9 frames, which stand on the bottom; that gives us depth of frame; and if these nine frames are filled three-fourths full of good honey, the bees will commence the winter under the honey, and eat upward toward the top. The honey is all the time directly over the cluster. The bees work upward as they eat the honey, and it takes a long cold winter to get to the top; and unless they

do eat up to the top, they won't have dysentery, and they will stand a good deal of cold weather. We have some Langstroth hives, and a few Simplicity L. hives which we made last winter, so that, with what we had before, we have now enough quadruple L. hives to hold 104 colonies two stories high, using eight frames in each story. They are double walled with chaff filling. The chamber, or roof, covers the upper stories. The upper stories are movable. We can set them off the lower stories, each one by itself; this makes a good hive, safe to winter in. It has depth, as we leave the upper stories on full of good sealed honey. We have used a few of them now for three years with good success.

We have one quadruple L. hive that has been in use three years, and has never lost a colony in these three past hard winters, and no dysentery either. They had all the pollen they gathered, but I have always been particular that they had the upper stories filled with honey. Standing by the side of it is one of my tall quadruple hives (frames 21 in. high, nine frames), in which, three years ago, we put an imported Italian queen that we got of C. Daut. She is alive yet, and has a good strong colony. I have drawn two brood-frames from it this spring. This hive has not lost a colony in the three past years. We have been very careful that the hive had all four colonies in good trim in the fall, plenty of bees, and frames well filled with honey, because our imported queen was there.

Platteville, Grant Co., Wis., May 25, 1885.

CHAPTER II., WRITTEN THREE MONTHS AFTER.

We handle bees differently, perhaps, from any one else, but we get the honey—not quite as much this year as last, but we have 28,000 lbs., all extracted. Our best day we took out 2960 lbs.—2075 lbs. of it with one extractor. There were 12 days when we took out from 1000 to 1500 lbs. with one machine.

E. FRANCE & SON.

Friend F., I have no doubt that the tenement-hive idea, or, if you choose, having four colonies in one hive, placed so close together that they receive the benefit of the animal heat from each other, will be a safer arrangement for severe winters than we can possibly secure by having each colony in a separate hive. A great many who have tried tenement hives—ourselves among the number—decided that we could not stand the complication resulting, and the difficulty of manipulation. Some of the advocates of tenement hives say they would as soon handle bees in that way as in any other, but I can not agree with them. It seems to me that a better way still would be to have eight colonies in a single hive—four above, and four below, with entrances so the bees could go out when the weather permits. Eight colonies put closely together in this way, with a very thin board separating the clusters, would have a wonderful power in resisting the encroachments of frost. But then, there is the difficulty of handling the lower combs. After all such experiments, I have decided that I want each colony or nucleus in a separate hive, and that hive at least seven feet from any other. I am ready to change my mind, however, if any plan offers that will help us out of the difficulties I have mentioned.—I am very glad to receive such a report as you make in your second chapter. Wisconsin seems to be destined to keep up her reputation this season as well as last.

FRIEND HILTON'S BEE-HIVE.

A CHAFF HIVE WITH A HINGED CAP.

AT the State Convention last winter you told me if I would furnish the cuts you would be pleased to give an illustration and description of my hive.

The open hive shows two sets of crates filled with $1\frac{1}{2}$ -pound sections, giving surplus room for 90 lbs. The closed hive simply shows the general appearance.

GEORGE E. HILTON'S CHAFF HIVE.

The outside is made of $\frac{3}{4}$ lumber, two feet long, the ends nailed on the sides, making outside dimensions about 24x25 inches. This leaves the side walls 6 in. thick, and end walls 4, to the top of brood-nest. There it is decked over flat, allowing the whole upper part to be used for surplus for extracting. I use a super holding 14 frames; and for comb honey a crate similar to the Heddon, only it holds forty 1-pound sections, or thirty $1\frac{1}{2}$ -lb. sections, and can be tiered up, and the cover will shut over all, leaving an air-space all around.

EXTERIOR VIEW OF HILTON CHAFF HIVE.

During the present hot weather I raise the covers

an inch or two, which gives a circulation and permits the bees to remain in the cases. I have in my yard at this time some colonies with 80 sections nearly complete; and when they swarm, oh my! what swarms!

For wintering, when I remove the surplus in the fall I place on a Hill device, spread over a piece of burlap two feet square, and press in a cushion that just fills the upper part to where the cover comes off. This is hinged at the back, and rests on two brackets, and makes two shelves—one at the top where the smoker now stands, and one inside. The alighting-board, which is also hinged, rests on the sand or sawdust in front.

For the past five years my winter losses have averaged about 10 per cent, and my bees were never so strong as the past spring.

G. E. HILTON.

Fremont, Mich., July 25, 1885.

SOME VALUABLE SUGGESTIONS
FROM J. A. STAGG.

HOW TO CLEAN A SMOKER.

BORE a $\frac{3}{4}$ -inch hole in the bottom of the smoker, so that the front edge of the hole will be under the back edge of the small bent tube. Now cut a circular piece of tin about the size of a half-dollar, and fasten it over the hole by driving a tack through one edge. If the tack is driven through the edge opposite the small staple which holds the wire spring on, the L of the spring will aid in holding the tin lid in place. Now slide your lid to one side, and you can get at the tube without trouble. Why not make the smokers so, friend Root?

RED-CLOVER HONEY.

My bees, Italians, are storing considerable red-clover honey at present. "How do you know it is red-clover honey?" Because the clover-fields near the apiary are full of Italian bees; and because the honey being stored has the unmistakable red-clover flavor.

A QUEEN'S FREAK.

Last summer while attempting to introduce a young Italian queen, she took wing and "skipped out." The next day a neighbor living about a quarter of a mile distant was examining one of his colonies, which contained a choice tested queen. Upon lifting a frame he discovered two queens—one his tested queen, the other a fine young laying Italian. A careful examination failed to disclose any traces of queen-cells. I saw this young queen, and, from peculiar markings on her body, did not hesitate to pronounce her the identical queen which had escaped from me the day before.

CIGAR-BOX FEEDER.

Take a cigar-box and put in a partition $\frac{1}{2}$ inch from the front side. The partition should extend to within $\frac{3}{4}$ inch of the top. With a sharp bit and a chisel or knife, cut out that part of the bottom between the partition and front. Next cut out a square in the lid, say $2\frac{1}{2} \times 2\frac{1}{2}$ inches, and tack a piece of wire cloth over it, allowing the wire cloth to sag considerably. Now pour in a little melted wax and run it around the corners by holding the box in different positions. This will prevent any leaking. Put in a few clean shavings or cut straw to prevent the bees from drowning, and your feeder is ready for use. Cut a slit $\frac{1}{2} \times 4$ inches in the cloth over your bees; set the feeder so that the

opening cut in it will be directly over the slit, and pour in your feed. In cool weather, cover with several thicknesses of cloth or old carpet, so as to keep in the heat. This is decidedly the best cheap feeder that I have ever tried—no robbers, no drowned bees, no stings, no expense.

Greensburg, Ind., July 29, 1885. J. A. STAGG.

Friend S., we have thought of making smokers in the way you describe, but it makes them more complicated, and there will always be a chance for air getting out under that tin slide. We try to have our bellows so tight that, when the blast-tube is closed by the finger, the bellows can not be closed, even with considerable pressure; and every bellows should be thus tight to work effectively. — Where a young queen gets away under the circumstances you mention, she is liable to go wherever it happens, or where she hears bees humming. As a rule, though, they come back to the place from which they took wing.—Your feeder is substantially the one figured in Mr. Langstroth's book. You say, in enumerating its good qualities, "No expense." Were you to make fifty or a hundred, I think you would find that they do cost something, after all.

THE BRANCHVILLE CASE OF POISON HONEY.

SOME ADDITIONAL FACTS IN REGARD TO THE MATTER.

WE take the following from the Branchville *Banner* of July 23:

Editors Branchville *Banner*:—The July number of *Gleanings in Bee Culture* contains an article on the subject of the recent cases of poisoning from honey, with which your readers are familiar. There is also a letter from Prof. A. J. Cook, of the Michigan Agricultural College, who asserts that the poisoning could not have resulted from the presence of *Gelsemium* in the honey, or, if present, the drug must have been maliciously placed there.

Without being an expert in matters concerning bees and honey, the writer believes that the cases referred to in GLEANINGS, in the letter of Mr. and Mrs. Dukes, were the result of poisoning by *Gelsemium* contained in the honey, and begs to submit the following reasons for that belief. The whole question is certainly worthy of close investigation.

1. The symptoms produced by the toxic action of *Gelsemium sempervirens* are:

Diaphoresis; muscular relaxation; dizziness, and dimness of vision; dilatation of pupils; reduced pulsation; retarded respiration; absence of stupor or delirium.—*U. S. Dispensatory*.

Every one of these symptoms was present in all the cases above described.

2. Pavv says: "The honey, again, of certain countries and districts is well known to possess certain special qualities, dependent on the flora of the locality. * * * Hence also the deleterious qualities which the honey of Trebizonde, upon the Black Sea, has long been known to possess, and which are due to its collection from a species of rhododendron, the *Azalia pontica*, which grows upon the neighboring mountains."—*Food and Dietetics*.

Every one knows how the odor, the taste, and coloring matter of flowers are frequently imparted to honey. What ground is there, then, for asserting that the toxic principle of flowers can not be also conveyed to the honey?

3. That the flowers of the yellow jessamine are very poisonous, is well known in the South. One instance will suffice. Some two months since, Mrs. Clark, a Northern lady, staying in Orangeburg (18 miles from this point) gathered a large bouquet of yellow-jessamine flowers, and thoughtlessly chewed the blossoms, while walking. An hour afterward she exhibited every symptom described above, and recovered after several hours, vomiting very freely.

4. On the coast of South Carolina, and on the Sea Islands, where the jessamine grows in rank luxuriance, the poisonous qualities of honey (especially wild honey) are known to everybody. No planter or colored person dares to eat wild honey there. During the war many of the Federal soldiers, who ate freely of this honey, found out its deadly effects to their cost, although no deaths are known to have followed from this cause.

5. The honey which caused the Branchville poisoning was obtained by Mrs. Jacob Dukes from her father, who lives near the edge of a swamp where jessamine grows in great abundance, and where, during the present late spring, no other flowers, or very few, were accessible to the bees.

In the case of Mrs. Dukes, her son, and the colored children, we see the effect of a poison which is traced clearly and indisputably to the honey. This poison in its action produced every symptom of *gelsemium* poisoning, to the minutest particular. The bees did make the spring honey chiefly from the yellow-jessamine flowers; and the supposition that any one mixed any drug with this honey in the comb, is out of the question, to any one knowing the parties. Is not this very strong evidence as to the active agent producing the sickness and deaths above recorded? The strength of these facts can not, at all events, be shaken by a simple assertion or opinion from any source whatever. A. T. P.

Friend A. T. P., our thanks are due to you for calling our attention to the fact that so good an authority as the U. S. Dispensary describes so plainly the poison from *gelsemium*. As you state it, I should say there was no mistake. We have almost positive evidence in regard to the source of the honey; and hereafter when these symptoms follow after eating honey, we may be pretty sure it is owing to the presence of yellow jessamine in the vicinity. It may be, that honey made from this plant is not always equally poisonous; but in any case, where it is known to grow extensively people should be careful about eating freshly gathered uncapped honey. It would be quite a valuable point now to ascertain whether this honey remains poisonous after being thoroughly ripened and capped over by the bees.

AFTER-SWARMS; CAN THEY BE PREVENTED?

DOOLITTLE'S IMPROVEMENTS IN THE PLANS ALREADY IN USE.

WHATEVER may be said regarding the prevention of increase where an apiary is run for extracted honey, one thing is certain: That an apiary so worked as to obtain the best results in comb honey must of necessity give more or less natural swarms. I believe with many others, that just one natural swarm from each old colony in the spring will give better returns in comb honey than it is possible to get by any other mode of management; while if more than one swarm are allowed from any one colony, with such an after-swarm goes at least a half of what might be obtained as surplus; hence it becomes very desirable to prevent all after-swarms. For this reason the subject has been written about and talked upon for the past quarter of a century, and many plans of prevention given, the most of which have proven to be a failure when put in practice.

Among the plans given, two methods have stood, and are the most prominent; the first of which is the cutting of queen-cells, and the second the moving of hives from the old stand to a new. As I wish

to say a few words regarding each I will speak of the cell plan first.

CUTTING OUT ALL THE QUEEN-CELLS EXCEPT ONE.

We are told if we open the hive at any time during the first five or six days after the swarm has been cast, and cut off all the queen-cells except one, no after-swarms will be the result. If the bees desire more queen-cells they have plenty of brood yet sufficiently young from which to rear more queens. In nine cases out of ten such cells are formed, and the cell which was left is destroyed, or the young queen killed as soon as she hatches. This results in after-swarms fourteen to eighteen days after the first one issued.

Now for my improvement on this plan, which I have used without a failure for over ten years. It is very simple. Just listen a moment in the evening, at the side of a hive which cast a fine swarm eight days previous, and if the swarm issued upon the sealing of the first queen-cell (which as a rule most swarms do; there are exceptions, we all know), the young queen will be hatched, and her peeping will tell you an after-swarm may be expected the next day. Early the next morning open the hive and proceed to shake the bees from every frame in front of the entrance so they can run in, and so you can easily see every queen-cell, so as not to miss any. Now cut off every one, and you are sure of the thing. No "hope so" or "guessing" about it.

"But," says a friend, "Bro. Heddon tells us, on page 415 of GLEANINGS for June 15th, that 'if we are going to produce cheap honey at a profit we must manipulate hives more and frames less,' while the plan you give is one for the manipulation of frames."

"Have you tried Bro. Heddon's plan, as given on page 415?" I ask.

"No," says he; "have you?"

"Yes, I tried it last year, which was the poorest honey season I ever knew, and it worked in every instance, so I recommended it to Bro. Burns, of Thorn Hill, and to Bro. Nesbit. Well, this year fifteen out of every twenty so tried have cast after-swarms, while Bro. Burns says every one of those he tried has swarmed again, and Bro. N. has fared little if any better. Hence the Heddon plan goes as an entire failure in this locality, and I am blamed for recommending it. If we are to go through all the manipulation of hives, only to come to the manipulation of frames at the end of the lifting and lugging of hives, I beg to be allowed to manipulate frames without going through with the former; for the two operations can not help produce cheap honey. But, stay a moment, friend, for I have learned something from these experiments, which may be of help to the bee-keeping fraternity. It is this: Have a box or hive with the desired number of frames (I use frames of comb) in it, and when a prime swarm issues take the box to the hive from which the swarm came, setting the frames out of the box near the hive. Now open the hive and take out the frames of brood, putting them in the box. If the combs of brood seem to still be well covered with bees, and the weather is warm, shake a part of them off in front of the hive, before putting the combs in the box. If few bees or cool weather, put all in the box, setting the box in the shade, and a rod or so from the hive, as soon as all the frames of brood and the bees on them are in it. Now put the frames brought from the shop into the hive, and

re-arrange it, by which time the swarm will return if the queen has a clipped wing. If not, they are to be put back in this hive. Next put the combs of brood in a hive where you wish a colony to stand, and the next morning give a queen-cell, which will hatch in 12 to 24 hours, or give a virgin queen, which will be accepted if done at this time. In this way I secure all the advantages Bro. H. does by his plan, and make the prevention of after-swarms a perfect success."

Borodino, N. Y.

G. M. DOOLITTLE.

SOME VALUABLE HINTS FROM OUR GOOD FRIEND MRS. JENNIE CULP.

"GATHER UP THE FRAGMENTS THAT NOTHING MAY BE LOST," ETC.

FRIEND ROOT:—GLEANINGS for July 15th is received and contents noted, and I find (as is often the case) some articles which make me feel just as sister Chaddock says your foot-notes make her feel, and I have concluded to let forbearance cease to be a virtue, and "answer back." I can truly sympathize with her concerning foot-notes, and extracts published from private letters, for it makes my head swim now when I think of the "answering back" I am compelled to do on account of them.

Article II.—In your "Apology to our Ohio Brethren" you ignore the sisters, as though you did not owe them an apology too. Perhaps you are not aware that a sister nominated you for the presidency, and that the sisters helped elect you without a dissenting voice. We the "sisters" are perfectly willing the "lords of creation" shall hold the lines; but we feel it is our privilege to occasionally step out and tell you the way you *ought* to go.

Art. III.—A little plain talk with sister Chaddock. Allow me to say, sister C., before commencing, that I have no wax-extractor to sell, neither am I employed to puff them or any other labor-saving machine. Your article on how you made beeswax was the cause of my losing nearly a whole night's sleep. It was not the hard (unnecessary) work you had done that worried me, as much as it was your determination not to be enlightened on the subject, and vow to burn, hereafter, all the fragments of comb and wax that come in your possession. The command in Holy Writ is, "Gather up the fragments that nothing be lost," and this can be done most effectually in the bee-business. Washings of cappings and honey-vessels will keep the family supplied with delicious vinegar; the old broken bits of comb-trimmings, and scrapings of hives and honey-boxes, with the use of one of A. I. Root's wax-extractors (I wouldn't be bothered with one of his 35-cent ones), will transform it into beautiful wax, with scarcely any more attention than you would give a kettle of potatoes boiling for dinner, and no muss either. I know what I say to be true, for I have used one for four years, and could not be persuaded to do without one, if I owned only half a dozen colonies of bees. The proceeds from my little apiary, in the form of wax, have netted me in the three years I have had charge of it, \$30.00. The fragments are worth saving, dear sister; but I must acknowledge to you the wax-extractor had to be thrust upon me by a kind and loving husband, who would not consent to my musing with it in the oven, burning fingers, and occasionally spilling wax on the floor or carpet, and you know it is not like

the old woman's grease—it won't rub off when it gets dry. Your article caused me to review 24 years of happy married life, and I saw, as I never saw before, how very kind my husband had been in thrusting upon me so many labor-saving machines, and how loth I was to accept them on account of the expense (for we were poor), and yet every one of them has proved to be a benediction to me. How slow—oh how slow! some of us are to see the point as to what is best for us!

A word about the bees, and then I will try to stop. The fruit-bloom yield of honey was pretty good, enabling the bees to bridge over to basswood (no white-clover honey, as the old crop of clover was frozen out); basswood of short duration. We are not expecting any surplus this fall, unless we get it from buckwheat. I am going to be satisfied with past blessings in the honey line.

Oh, yes! I am not done yet. A word to sister Nellie—I am going to wait and see what the elder sister bee-keepers say on the Sunday bee-keeping question; and if they do not answer you to suit me, I will tell you a "real rooster story" that helped me wonderfully on that line.

Hilliard, O., July 29, 1885. MRS. JENNIE CULP.

My good friend, I am very glad that I have succeeded in making you feel as if you wanted to answer back. So it was the sisters who thought I would do for president, was it? May God give me strength and wisdom, that they may not be disappointed—By all means give us the rooster story, Mrs. C. Why, I can imagine one thousand or more juveniles clapping their hands. Just think of it, little friends! Mrs. C. is going to give us a real rooster story, and it is something about Sunday-schools too, I am pretty sure; but she must send it right along for next juvenile, and not wait for any of the elder sisters.

SOME SUGGESTIONS AND CORRECTIONS FROM C. C. MILLER.

CAN ADULT BEES SECRETE WAX?

I DON'T know; but I can hardly see that it is proven on p. 536, as you, Mr. Root, seem to agree. I see nothing in the facts stated, to show that any wax was *secreted*, only *worked* by the old bees. Of course, you must have noticed that, as a general rule, no freshly secreted wax is used in making queen-cells. I think in all the thousands of queen-cells that have come under my observation I never saw a light-colored one unless the surrounding comb or combs were light.

BEES USING OLD WAX OVER AGAIN.

Indeed, I think bees use old wax over again much more than most bee-keepers suppose. The elder Mr. Oatman once said to me that they thought seriously of melting up their old combs and giving the colonies fresh foundation, just because, with old comb in the hive, they could not secure sections of the purest whiteness. When I used wide frames I practiced putting a brood-frame between two wide frames, with no intervening separators; and whenever they were allowed to remain thus till the sections were sealed over, or partly so, the capping was sure to be more or less dark. Sometimes the capping was uniformly dark, sometimes mottled with bits of white and dark, about half and half, but easily distinguishable; but in no case do I rec-

ollect a section of virgin whiteness sealed under such conditions. In this case they must have carried the old wax from one frame to another. Perhaps if we want the whitest sections it will pay us to remove the superfluous wax from top-bars and elsewhere. I think I get whiter sections by using Heddon's honey-board, perhaps because the bees don't like to carry the old wax so far.

A SUN WAX-EXTRACTOR.

Don't be alarmed—nothing patented, complicated, nor even original, only to show how easily it can be done. As I run altogether for comb honey I don't get much wax; but small quantities are always accumulating or wasting; and with no better convenience than the sieve and pan it has been more or less a nuisance. For some time I have been noticing the advertisements, to know what kind of wax-extractor to buy; but the trouble with all was, that fire heat must be employed, and I wanted something that would take care of itself, by my merely throwing in the scraps. So the other day I gave Charlie instructions to make one. He took a box 2 ft. long, 2 ft. wide, 1½ ft. deep (I don't think the size essential, but he happened to find one of that size), put a shelf in it on which was placed an old black sheet-iron dripping-pan. One corner of the pan was split open, and the pan (or, rather, the shelf) very slightly slanted, so that, as the wax melted, it would slowly run out of the open corner, and under this corner was placed a stone crock holding one or two gallons, and nearly filled with water. The box was made bee-tight, and covered by a window-sash that had been lying idle in the cellar; and as the sash was too large for the box, boards were nailed on two sides of the sash, to make it fit. That's all there is of it—an old box, dripping-pan, window-sash, and stone crock. Not an ornamental thing, by any means, but it does nice work. All that is needed is to throw the scraps into the pan, and the pure wax drops into the crock, leaving the sediment on the bottom of the pan. It runs only in the middle of the day; but Charlie hastened it very much one day by putting a looking-glass so as to reflect the sun upon it. I don't know that it would do for large quantities, but I have got three or four pounds of very nice wax from it.

GETTING WAX FROM OLD COMBS.

One would almost infer from Mr. Swinson's experiments on page 533, and your comments thereon, that a frame of comb after being in use ten years had absolutely less wax in it than when first made. I doubt this. I don't think the wax evaporates; and after the first cocoon is left in it, the bees can not get at the wax to take it away, except at the edges of the cells. I think less wax is usually obtained from old comb than from new; but the wax may be there for all that. Suppose you try this experiment: Take an old black comb; cut or break it in two; and when tolerably warm, mash up the one piece into a solid ball, and, leaving the other piece whole, place the two where they can have the full benefit of the hot sun for some days, or give them a slow fire heat. The piece left whole, if the heat has been strong enough and long enough, will be found scarcely any thing but dry cocoons, easily pulled apart; whereas the other will still be a solid ball with much wax in it, and I doubt if you can get it out. Burn each in the fire, and see the difference.

C. C. MILLER, 179—340.

Marengo, McHenry Co., Ill., Aug., 1885.

Thanks, friend Miller, for your correction.

I agree with you in what you say; for I have observed the same many times. In fact, I have seen pieces of new dark comb as large as my hand, because they were built between two old black combs. I am glad you have suggested this caution in regard to getting our comb honey capped with white cappings. Your suggestion, that we get whiter comb honey by using the Heddon honey-board, is new to me. I have been struck with the remarkable whiteness of a large lot of comb honey just purchased. It was secured by the Heddon system.—Thanks for your report in regard to the sun wax-extractor. In getting wax out of old black combs, don't you think a wax-press described in the ABC would get it out pretty nearly?

OLE FOGY NOT DEAD YET.

HIS OPINION ON CLIPPING QUEENS, ETC.

BRO. ROOT:—I quote from page 529, Vol. 13 of GLEANINGS: "Friend S., in regard to bees always alighting, that sentence caps the climax in helping us to decide that you are greatly given to notions. Have you forgotten the perfect hailstorm of facts rained upon the head of poor Ole Fogy a year or two ago, and the way in which we made him come out of his cover and own up and take back his words?"

Now turn to page 741, Vol. 11, and read Ole Fogy's last article that he ever wrote on that subject, and your own inevitable foot-note thereto, and I fancy somebody else will have to "own up and take back." That hailstorm of facts you speak of was a very small matter, only a mist that nobody feared. Oh, no! I still hold the fort, and expect to hold it till there's a stronger battery opened against it than ever has been yet. I took the position, that a natural swarm issuing *for the first time from a hive, in a normal condition*, never, never, never goes off without first settling or clustering, *providing always that there is a decent place convenient for them to settle on*. I'm on that platform yet, and will stand on it till it falls; and I am happy to know that the number is growing beautifully smaller and smaller every year, of those superstitious people who think they must be on hand when their bees swarm, to make all the noise and confusion they possibly can with horns and bells, tin pans, and even looking-glasses and shot-guns, to keep their bees from going to the woods "mit out settlin'." Others, again, just as unreasonable, but ashamed, perhaps, to be making such a racket for their neighbors to hear, quietly go to work and cut off the queen's wing so she can not fly; and don't you know that, if you have your queen's wings cropped you have got to watch them closer than if they were not cropped at all—I mean in swarming time? I want no cropped queens in mine; do you hear?

OLE FOGY.

Allendale, Ills., Aug. 5, 1885.

Friend F., it seems as if there were a couple of us who have been careless or forgetful. While you have Vol. 11 in hand and open, reading p. 741, just turn two leaves more and read page 745; also notice below, the "foot note."—In regard to the editorial you refer to, please notice that friend Salisbury says, "*Bees always alight*." He doesn't specify first or second swarms, or name any condition, as you do.

MY EXPERIENCE WITH THE BEE-POISON.

BY REV. L. L. LANGSTROTH.

IN 1838 I put two colonies of bees in an attic closet, but I made no experiments of any kind with them; they were simply looked at and admired. In 1839 I fairly began my apiarian career, and soon found that to experiment much with bees, meant to get many stings. At first these were not only quite painful, but caused severe swellings. I dreaded to be stung the latter part of the week, for often one eye would close and the other nearly so, and to preach in such a condition was by no means a pleasure. If stung on the hand, my whole arm would swell so rapidly that if my coat was not seasonably taken off, it had to be ripped off. In short, I was a regular martyr to the bee-poison.

My second year's experience was much more favorable, and in the course of a few years I became almost bee-proof. In the pressure of business, and my zeal for studying the habits of the bee, I preferred to be stung occasionally, rather than to lose time by wearing a bee-hat. The pain of a sting was seldom very severe, and not often caused much swelling. My experience was the same with that of most bee-keepers who had persevered in spite of stings, until at last their systems became accustomed to the poison.*

A few facts out of many that might be given: I once agreed to help a farmer to move a hive to a new location. He assured me that the bottom-board was securely fastened. It fell off before we had got more than a few steps with our load—covered with bees, some of which were crushed—and the air at once was filled with the enraged insects. The farmer dropped his side of the hive and ran away; it fell against me, but I held on until I lowered it to the ground; and then made the best of my way into the house. Perhaps a hundred or more stings were pulled out of my face and head! and yet in a few hours one could hardly have noticed that I had been stung at all. When visiting that great man, Dr. Jared P. Kirtland, of Cleveland, Ohio, he wished me to examine with him a colony of bastard (hybrid) bees. The doctor was armed with bee-hat and gloves—both of which I declined to use. We quieted them pretty well with smoke, when he began to discuss some point in bee culture with his usual animation. Soon his gesticulating hand was doing quite a business, the bees became furious, and paid all their respects to me; and how many stings were pulled out of my face and head I can not tell. As soon as this extracting work was over, I said: "Doctor Kirtland, I protest against all eloquence in the vicinity of bee-hives—especially when you are clad in proof armor, and I have none!" Although ever so well stung, the pain was soon over, and in a short time no visible proof remained that a bee had stung me.

In 1874, after the death of my son, my health became so impaired that I sold all my bees. The next spring an entire change seemed to have come over me with respect to the bee-poison. I first noticed it in extracting some stings with the poison-sac attached, for a friend who wished to procure the bee-poison in a perfectly pure state. I had noticed at

*The Austrian who came over with Mr. S. B. Parsons' Italian bees, when stung, would leisurely take out of his pocket a vial to anoint the sting with his favorite remedy! Seeing how indifferent Mr. Cary, myself and others were to stings, he soon ceased to produce the vial.

the beginning of each year's work among my bees, that the poison affected me in various ways, and my wife would often have to awaken me when she heard me unconsciously moaning in my sleep. The night after pulling out these stings, this moaning became so pronounced as to awaken the friends with whom I was staying, and alarm them with the fear that I was dying. Intense dryness of the tongue and fauces, accompanied sometimes by what seemed to be an aggravated form of heart-burn, smarting of the eyes, a heavy, drooping sensation in the eyelids, breaking out of fiery spots over various parts of my body, a disposition to almost tear the flesh of my cheeks, dreaming of the most excited kind, full of violent motion — these and many other symptoms were of frequent recurrence at the beginning of each bee campaign.

After getting the medicinal bee-poison, as before recited, the effect upon me was so severe that I became really alarmed, and earnestly sought to protect myself against any recurrence of such unpleasant symptoms. I soon found this was next to impossible. To converse with those fresh from handling bees — nay, even to receive letters or postal cards from them, was to be poisoned again.[†]

Ten years ago, being at my old home in Greenfield, Mass., I engaged to visit my friend Wm. W. Cary, of Coleraine, one Saturday afternoon, intending to preach to a congregation where for some years I had served as their pastor. The day was a charming one, and I was quite happy at the thought of meeting so many old friends. Mr. Cary had been handling bees all day, and was well charged of course with the bee-poison. Almost as soon as he had shaken hands with me, my eyes began to smart, my eyelids to feel heavy, and my face to itch. My spirits sank at once, and the thought of preaching and seeing my old friends caused me only anxiety; in short, the very bottom of all hopefulness seemed to drop out, as it were, in a few moments. Explaining my reasons, I sought other quarters, but the pleasure of my visit was essentially spoiled. Imagination! I hear some one saying. Does imagination cause burning eruptions on the body, constant roaring in the ears, as though near a waterfall, to say nothing of moaning in sleep, etc.?

From 1875 to 1881 I dreaded the return of each bee-season. My letters were all read by some member of my family, that I might handle none from bee-keepers. I felt that, let my general health be what it might, I could do nothing more with bees. While I could easily trace much of my suffering to the bee-poison, I could not believe that it was the cause of the head trouble from which I have suffered so much, for I was a frequent martyr to this many years before I kept bees. Now, had I given my experience with the bee-poison from 1875 to 1881, I should have left the matter in such a shape as to prejudice many against having any thing to do with bees. I should only have given the actual facts in my case; but for want of other facts not then duly weighed by me, my facts would have seemed to warrant inferences just the opposite from the truth.

In the spring of 1881 my health being more fully restored than for some years, it seemed to me almost an impossibility to keep longer away from the bees. A new thought suddenly occurred to me.

[†]The susceptibility of some persons to the bee-poison, seems to be as great as that of others to the poison-ivy. I can handle this with impunity, while I have friends who can not get near enough to it to see it, without being poisoned by it, if the wind blows to them from it!

Suppose a person after long use of tobacco or opium should give them up for some time — long enough for the effect they produce to pass away — and should then attempt to take the old, big dose! would he not be naturally alarmed at the result? May I not be mistaken, then, in supposing that any great change has taken place in my system, as respects the effects of the bee-poison upon it? and may not my painful experiences of the last six years be accounted for in another way? So long as I kept bees and dealt so largely in queens I was compelled each year to inoculate my system so fully with their poison, that however severe the ordeal at first, I soon became indifferent to it. Now being under no such necessity, I stop short every time of full and repeated doses. Suppose that I take such doses again. With fear and trembling on the part of my family, but with scarcely any on my part, I determined to test the matter, for as even the presence of freshly extracted honey in the house was enough to bring on another attack, I felt that I must get out of the world before I could escape from this dreaded poison. I determined, therefore, to make full proof of my new theory. Without any bee-hat, I helped my friends to extract their honey, all the time saying to the bees, "Sting me as often as you please;" and as they were gentle Italians, I did not scruple by somewhat rough treatment, to make them do much more than they naturally wished to, in the way of stinging. From the very first I did not suffer nearly as much as I had done every year since I ceased to work with bees! and little if any more than I had done every year when first handling them. In about a week I was again bee-proof, and launched out at once into a course of experiments (all in vain) to control if possible the impregnation of queens.

How can I ever describe my delight in handling again the movable frames! In the apiary of a neighbor, Rev. McGregor, I fully proved that with small strips of foundation for guides, I could use my comb-guides, or guide-frames, and secure from Italian bees the same perfect worker-combs that I used to get with these guides from the black bees; thus realizing a favorite idea of one of our greatest bee-keepers (Doolittle), viz., getting perfect worker-combs with the least use of foundation.

While handling frame after frame of such combs, and feeling as much enthusiasm as I did in 1853, when I first saw that the bees would follow the triangular comb-guide, I explained to the Rev. McGregor (apologizing for the seeming play upon his name), I must make those words of Rob Roy in Scott's novel, my own: "My foot is upon my native heath — and my name is McGregor."

Unquestionably some persons are so extremely sensitive to the bee-poison, and so dangerously affected by it, that under no circumstances should they keep bees. To such persons my experience can be of no service.

Oxford, Ohio.

Friend L., the facts you furnish us in the above article are indeed valuable. You may be perhaps aware that others have been affected by the poison of the bee-sting in the same way you mention — among them friend Heddon. Now, is it not probable that a good stinging might so inoculate friend H. that it would set him all right? The remedy might be in some respects a bold one; but if it were my case I think I would risk a

trial of it. If I understood you correctly, it is now your opinion that, had you at any time, while you were thus affected, been stung enough so that your system had become thoroughly inoculated with the poison, these bad symptoms would have disappeared. I am inclined to think that giving way to these feelings has often a good deal to do with it.

BEE BOTANY.

OR, HONEY-PLANTS TO BE NAMED.

HYPTIS EMORGI; A GOOD REPORT FROM THE PROCEEDS OF ONE COLONY.

I SEND you a specimen of a plant. It is a shrub or bush 4 to 10 ft. in height, with 50 to 100 shoots, from the size of your fore-finger to the size of your wrist, making a dense bush from 4 ft. to 10 ft. across the top. It has fine light-green twigs like knitting-needles, and long slim needle-like leaves of a very bright light-green color, which enables you to distinguish it from other shrubs at a great distance. It comes in bloom about the first of Oct., and continues till near the first of Nov. The bees swarm on it and roar like a swarm. However, they can not gather honey so fast as from bass-wood; but they store so much honey, that I had to extract twice while it was in bloom to give the bees room to raise brood.

I have kept bees in Missouri for 12 years, and have investigated Arkansas and Kansas. I have read the honey reports in the bee-journals for 20 years, but have never read, or heard of any thing, or place, that will compare with this for bees and honey. Who ever heard of 14 swarms, and 600 lbs. good thick honey that weighs 12 lbs. to the gallon, from a start of one weak swarm in March? This, too, by natural swarming, and without the use of comb foundation, or any unusual exertion.

Tempe, Arizona.

JNO. L. GREGG.

The plant from J. L. Gregg is *Hyptis Emorgi*, Torr., belonging to the mint family (*Labiata*), to which so many of our best honey-plants belong. Its late blooming must make it valuable for bee pasture. I think it has never been found east of the Mississippi.

W. S. DEVOL, Botanist.

Ohio Ag'l Exp't Station, Columbus.

FETID MARSH-FLEABANE.

I send you by this mail a weed, called here polecat weed.

E. A. BUTLER.

Terry, Miss.

Plant sent from Terry, Miss., by Mr. E. A. Butler, is the fetid Marsh-Fleabane (*Pluchea foetidis*, D. C.). This and allied species are found generally distributed throughout the eastern, southern, and middle United States, some of them in salt marshes and others in fresh-water marshes and along the banks of streams and shores of ponds, the above-named species being one of the latter class. Like most of the order *Compositae* it blooms rather late in the season—August to October. It grows 2 to 5 ft. high, minutely pubescent and glandular; leaves opposite, 5 to 8 inches long, coarsely serrate, resinous dotted; the small numerous heads of purplish flowers on slender pedicels are clustered in a panicle or paniculate corymb.

Columbus, O.

W. S. DEVOL, Botanist.

MOUNTAIN SPINACH.

I was advised to send you a specimen of something that grew in my flower-bed. We supposed at first it was some of the seed I had sown. It had at first a faint resemblance to sunflower, and grows seven feet tall. The plant was examined by a great many, and no two agreed as to what it was.

Marengo, O.

MRS. ABBEY A. SHERMAN.

The plant from Mrs. A. A. Sherman is Orache, or Mountain Spinach (*Atriplex hortensis*). It is a hardy annual 2 to 3 ft. high, very popular in France, into which country it is said to have been introduced in 1548. It is little grown in the United States, but seeds freely, and in some gardens becomes a troublesome weed.

W. S. DEVOL.

Columbus, Ohio.

Please name, and tell how inclosed plant ranks as a honey-plant. It is known here as a bad weed in young corn, and is called "Torment," or wild mint. Dorchester, Mo.

WILL T. ZINK.

The specimen from W. T. Zink belongs to the mint family; from the small cluster of leaves sent, and no flowers, I am unable to determine the species. If Mr. Z. will send specimen when in bloom I will endeavor to name it for him.

Columbus, O.

W. S. DEVOL.

PRIVET.

I send a specimen of a shrub now in bloom, which is every year covered with bees, and doubtless yields much honey. Will you please name it for me?

S. W. MORRISON.

Oxford, Pa., July 9, 1885.

Specimen of flowering shrub from S. W. Morrison is Privet, or Prim (*Ligustrum vulgare*, L.) found in woods and thickets in N. Y., Pa., Va., and westward to the Mississippi River, supposed to have been introduced from England, but this is doubtful. It grows 5 or 6 ft. high, and bears numerous small, white flowers.

W. S. DEVOL.

Columbus, O.

T. LANCEOLATUM; A FIRST COUSIN TO THE BASTARD PENNYROYAL.

Inclosed please find another specimen of the honey-plant I sent you for identification. The corolla is too deep for the bees to get the honey in the usual way, so I went to see how they did get it. The bee catches hold of the flower, and presses with his tongue and fore-feet at its slender neck, till it cracks enough to get his tongue in; then he slides it like lightning along to the honey. It was funny to see how eagerly he would slide his tongue along to the honey when he once got in. They did not appear to be able to get into some of the blossoms. This was something new to me, and I hardly knew whether to believe the bee made the crack or not; so I tried it with the point of my knife, and I found they would crack at the neck with a very slight pressure. Some would not crack at all; these may have been too old and not brittle enough. We sow wheat and oats for hay, and mow it in June. After a month or so, this plant comes up as thick as it can stand and lasts two or three months.

Soquel, Cal.

HENRY R. DAKIN.

The pretty little plant from H. R. Dakin is a species of blue curls (*Trichostema*). It is known to botanists as *T. lanceolatum*, Benth., and is a first cousin to the bastard pennyroyal so often spoken of in this department of GLEANINGS. It is a strong-scented herb with a soft pubescence covering the

whole plant; leaves about an inch long, entire; flowers purplish, borne in axillary clusters; stamens long exerted, curled. It is quite an interesting plant, about a foot high, the stems very leafy. Another species is found in the same vicinity, which strongly resembles this one, but the leaves are further apart on the stem, and the odor differs slightly.

Columbus, O. W. S. DEVOL.

MODERN TRANSFERRING.

FRIEND HEDDON'S METHOD.

IN response to your request I will tell you how we proceed to transfer bees from mixed styles of hives to our own favorite hive.

About swarming time I take one of my Langstroth hives, containing eight Given pressed wired frames of foundation, and, with smoker in hand, I approach the hive to be transferred. First, I drive the old queen and a majority of the bees into my hiving-box. I then remove the old hive a few feet backward, reversing the entrance, placing the new one in its place, and run in the forced swarm. In two days I find eight new straight combs with every cell worker, and containing a good start of brood. Twenty-one days after the transfer I drive the old hive *clean* of all its bees, uniting them with the former drive, and put on the boxes if they are not already on. If there is any nectar in the flowers, this colony will show you box honey. I run them together as I would one colony in two parts. Now to the old beessless hive. Of course, there is no brood left, unless a little drone-brood, and we have before us some combs for wax, for more foundation, and some first-class kindling-wood.

If you have no method by which you can use a full hive of frames, of full sheets of foundation, running a full swarm into them at once, by all means procure it without delay. But if any one has a mania for cutting up combs and fitting them into frames, my method given above does not prohibit them from using all the straight worker-combs the old hive contains, after first extracting the honey from them. Should any one wish to increase his colonies at the same time he transfers, only the following deviations from the above are necessary: Run the second drive into another hive of full frames of foundation, and use the old hive as before. Now that we have foundation perfected, so that the bees will draw the lines or side walls to full breeding depth, in from two to three days, why fuss with the old comb from the old hive? Having once experienced the advantages to be attained by using the above method, I shall certainly never go back to the old one. All of you know what a nuisance a few odd-sized hives are in the apiary; also some who have just started wish they had adopted some other style of hive. The above method of transferring will get all such out of their trouble.

The cost of foundation and new hives is fully made up by the better combs, and you have the change to better style of hive thrown into the bargain. I have thoroughly tested the results of the plan herein described, and am speaking from experience.

We have just practiced the above upon 72 colonies, and without a failure or mishap of any sort. I purchased 16 colonies of bees; that is, I purchased the bees, brood, and honey, with the agreement that I should return the hives and empty combs,

which I have done. We made each one cover two sets of combs in two brood-chambers, with two queens, besides the surplus sets used above for extracting, and all are rousing strong. When you plan to double your colonies, you remove the old colony to an entirely new location, when you make the first drive. It is now my opinion, that, even without the use of comb foundation, in the days when we had none this plan of transferring would have been the preferable one. As we are cutting out the old combs for wax, we transfer any that we find, that are *perfect*, now that they are all clear from bees, honey, and brood. JAMES HEDDON.

Dowagiac, Mich., Aug. 6, 1885.

Friend H., in your concluding sentence, "Clear from bees, honey, and brood," I can readily understand how you are clear of *bees*, and, after the last drumming-out, clear of *brood*; but, how about the *honey*? Old box hives at swarming time, in our locality, are usually heavy with honey; and one great obstacle in the way of your method is some way of disposing of this honey. There is also more or less freshly gathered pollen, which we here consider worth even more than the honey, early in the spring. I presume enough of the old bees will go back into the hives to care for the unsealed brood, so that none of that is lost. The point you mention, of getting rid of the dauby and troublesome process of fitting old pieces of comb into frames, and fastening them by means of splints, transferring-wires, etc., is, I grant, a big step ahead. We decided long ago, in our own apiary, that we wanted no more combs at any price, that were not built on frames of wired foundation.

INTRODUCING VIRGIN QUEENS.

AFTER I saw G. M. Doolittle's article on introducing virgin queens, in Aug. 1st GLEANINGS, and as I had such a splendid opportunity to test it, I prepared to my nuclei this morning, and will give you exactly what I experienced on July 31st. I introduced 21 virgin queens to nuclei that had their queens taken away the day before, excepting three that had been queenless for several days. Of those virgin queens some were caged 15 days in the nursery, and some were caged only 3 days. I let them run in at the top of the hive, and they were, to all appearances, safe when I left them.

To-day Aug 5, I examined the nuclei, and found 9 missing from the 21. One of the three that were several days queenless accepted the one given them; the other two killed theirs. I found only one of them laying. Only one of the queens had her wings injured so that she could not fly when taken from the nursery. I destroyed her. All the others were fine large queens. About two weeks ago I tried another lot. The queens were just a day old, and the nucleus had been queenless about 2 days. I lost only two, I think, out of about 15, and some that had just hatched were accepted at once. I believe the action of the queens has every thing to do with safe introduction. I let one into a nucleus and she set up a terrible piping, as much as to say she was ready to fight any thing. The bees accepted her at once. Had she started to run she would have been killed. W. J. ELLISON.

Stateburg, S. C., Aug. 5, 1885.

He that is faithful in that which is least, is faithful also in much. LUKE 16 10.

MYSELF AND MY NEIGHBORS.

If any of you lack wisdom, let him ask of God, that giveth to all men liberally, and upbraideth not; and it shall be given him. — JAMES 1:5.

WHAT a grand thing is wisdom! I shall not take space this morning to illustrate how true is our text, to any great extent, but I shall confine myself mostly to showing you the importance of wisdom. Let me give you a little sketch of my dealings with my neighbors for the past twenty-four hours. While I was out in the field, a man came along wanting my name on a paper. The undertaking was a grand one, and I could wish it God speed with all my heart. But it was something out of my line of work, and I asked why he wanted my name first. He said he wanted it started by a man universally known in our county, and one who is known to be straight and upright in business, etc. He urged that my influence might help him greatly in getting the good cause started. I hardly need tell you that I am opposed to putting my name on any paper carried by a stranger. He showed me similar papers that had been carried around in other counties, and I pronounced the signatures genuine, and as belonging to the best men I know of, many of them; but I objected, until I knew more about him and the new movement. He asked me what he should do to remove my objections. Here is where I wanted wisdom to answer. I finally told him that, if the pastor of our church, and the deacons of our church, would give it their sanction, I would, if he

wished, head the list. Was it a wise thing to do? I thought so, and think so still. The pastors of our churches, and the deacons, are the best counselors I know of in the world, especially in a matter like the one presented.

We have been having exceedingly wet and rainy weather. Farmers all around are worrying about their grain, and the thrashing-machines have not yet got started, because, just as soon as the grain begins to be so it would answer tolerably well to thrash, it rains again. Thrashers were coming tomorrow, and my four acres of wheat and rye would do pretty fairly. But just at dusk one of my near neighbors, who has thirteen acres of wheat, and who makes farming his business, called in my absence to inquire if I couldn't possibly let the thrashers do his grain first. One of the boys said he would present the matter to me when I came home from the railroad meeting, and then added: "Now we will see whether Mr. Root loves his neighbors as himself."

On the way home from the railroad meeting my neighbor met me. The question came as before, "What ought I to do?" What would a wise man do under similar circumstances? I told him to tell the thrashers that they should do his first (you see I did not know they were watching me to see how my *Christianity* would hold out). He had a good deal more than I had, and he has been a very kind neighbor, and I felt it a privilege to do him a favor. It is true, it rained before the thrashers got through with mine; but I have not been

sorry a bit. In fact, I felt glad to think my neighbor got his thirteen acres secured in nice shape. They commenced on mine about four o'clock. There were indications of a storm when we got started. If nothing happened we would get through before dark and before the storm. One of our best men, and one who usually handles the team, said he could pitch it on faster than the boy who was pitching it, if I thought it best for them to swap places. The boy, although a splendid one for any kind of hard work, was not much used to handling a team; and, against my better judgment, I consented to letting him load and drive. The load was on, and they were hurrying to reach the machine before the other load was off, when he uncautiously drove near where an under-drain had been made some time before. The wagon-wheels cut into the soft damp ground so that the load was stuck. The storm and night had almost come. What did wisdom dictate? My decision was to stop the machine, drive the other empty wagon alongside, and pitch off part of the load. One of the men belonging to the machine said he could make that team pull that load out of there. He worried the team, strained them to their uttermost, broke two whiffletrees, and even then did not get it out. Another man said his team would pull it out. I begged to have the empty wagon run down and take it slowly but *surely*. The new team broke the harness; and when they got it fixed, the horses got discouraged and would not try any more. Then scantling and plank were carried to pry the wheels out. After a delay until it began to sprinkle, indicating the coming of the storm, my plan was adopted. Now, I am very well aware that many good teamsters (which I am not) will often get a load out by *making* the horses take right hold of it when they think they can't do it; in fact, I have seen a good many loads pulled out, when I should have gone for another wagon. But all things considered, I like my way best. I do not like to see horses whipped, nor made to strain themselves to their uttermost. How often a little wisdom will help the work along! In this case a lot of hands stood idle a long while, while the rain came up and night came on, which might all have been avoided had I listened to the convictions of my best judgment, and not intrusted any one but an experienced driver, and one who knew the "lay of the ground." When the rain began to come down so as to make sure that the work must be stopped, all hands turned in and worked like "beavers" in loading what we did not get thrashed, on to our three empty wagons, and pushing them into sheds and warehouses, until by eight o'clock our grain was all secure. Men and teams worked hard, and strained every nerve, without supper or feed, until my property was secured. We are all human, and we all lack in judgment many times; but as I went to bed that night I had reason to thank God that our little band during that emergency were *honest* and *true*, for not even the smallest boy had shown the least bit of objection to their severe hard work, without a bite of supper until long after their usual time.

This morning our colt "Nancy" is sick. She probably worked too hard, especially as it was slippery and severe on a horse without shoes. Some of the friends declared that I had better send for a "horse-doctor." Now, then, where is wisdom once more? If I knew of an *educated Christian* man who has a good reputation for doctoring horses, I should gladly send for him. Do they have such in your neighborhood, friends? I considered the matter a while, and finally declared that if Nancy were going to die, she should die in the natural way, and not from the effect of powerful drugs which I have often seen administered to sick horses, and the poor dumb friends died after all. "Even the most powerful kinds of medicine wouldn't save them," so the horse-doctor said. Now, dear friends, very likely I have not any great stock of wisdom; but this one thing makes me feel happy: I am searching diligently for wisdom day by day; yes, pleading the *promise* God has given at the head of this little talk.

P. S.—Nancy is dead! When it was certain that her malady was no trifling one, I sent for our family physician and two or three men whom I knew to be conversant with horses, and more or less accustomed to handling sick horses. I was pleased to know that the doctor had once studied as a veterinary surgeon; but he frankly admitted that it is often very difficult indeed to decide what is best to do with a sick horse, and he is as much opposed as I am to guessing at the trouble and then administering powerful drugs. Many times relief is given by mechanical means or appliances, and of course we should always spare no expense in availing ourselves of the most intelligent and experienced help in saving these dumb friends of ours from suffering. But let us hope that the age is fast passing away, of *guessing* at the trouble and then *guessing* again that something that would kill a well horse might possibly hit the trouble and correct it.

HAVING FISH FOR PETS.

SOMETHING ABOUT HOW TO KEEP THEM IN THE HOUSE.

WHEN I was young, and did not have much to do, I loved pets of all kinds; but my favorites now are fish, and I nearly always have some of one kind or another. As I write I can look up to a shelf by a shady window and see four lovely carp in a five-gallon demijohn. It is clear and nice, and the fish look as if floating in air. The bottle is two-thirds full of water. The largest fish is about four inches long; but in the bottle he looks to be six inches. I prefer a bottle to a globe, because they hold more water, and so it does not need renewing so often.

The first week after putting the little fellows in their cage you must change the water four or five times a day; but after that they will not need changing oftener than once a week. You can always tell when to change the water, for they will put their noses out of it and hang their tails straight down and float around that way. Do not put the coldest water you can get on carp, but let it be with the first chill off, or it will stiffen them right out

and they will not live so long. Be sure not to feed them; if you do you will have to change the water every hour, and they get so uneasy that they are no pleasure to look at. They get enough animalculæ from most waters to keep them. We kept two in a tank where the water was run off on to a strawberry-bed once a week; and when we wanted the water for drinking we killed the fish. One was full of spawn, and the other was fat. They had been in about eight months, and had grown considerably. The well water was beautifully clear and sweet, so they must have lived on the animalculæ, for there was nothing else that we could see; and, in fact, we did not see them; but scientists say that the water is full of them. I take their word for it without looking, as I know I could not relish the pure, clear-looking water if I had seen bugs and snakes in it.

The largest of my pets loves to jump. He will start from the bottom of the bottle and rush to the top of the water, and spring quite to the neck. His fins will make quite a noise as he strikes the glass. I thought he was after flies; but I caught and killed a couple and dropped them into the water, and they would never touch them.

Minnows make nice pets, and they will catch and eat flies, and in a short time you can teach them to come to the top of the water for food; but you must have lots of water and very few fish, to be nice. I have kept two fish, about two inches long, tail and all, in a half-gallon Mason jar, for a year. A candy-jar is prettier, as it is clearer, and they will pay for the trouble. Of course, gold-fish are the prettiest, but they are not always obtainable, and they are not so active as carp or minnows.

Little folks, try one glass of fish for pets, and you will be delighted with them as soon as they get accustomed to their new home. Mr. Root thinks may be the hot spring would be a good place for carp. I do not know if they could stand the sulphur; but if they could, wouldn't it be nice! The pond could always be kept warm by the water running into it, and they love warm water.

Some one made an incubator—that is, a machine to hatch eggs—and put it where the hot water could run through it, and I heard that it hatched out the eggs nicely. I want to go and see it; and may be I will some day, for I love to work with chickens. Light Brahmas are my favorites, but we are trying Plymouth Rocks this year, and we have an incubator that we are getting ready to set, and, of course, I am interested in all such things; but we can not all have hot-spring incubators. We all can have carp, or fish of some kinds, however, even if they do not bring us much money. When Mr. H. was at Santa Barbara last week, he and a friend went up to the Old Mission, and they saw a large reservoir back of the building. They went to it and saw a lot of large carp in it, and they were so tame that they followed them all around the reservoir, looking for something to eat. The men hunted in their pockets for some crackers; but not finding any, Mr. G., who uses tobacco, crumbled off some and threw that in. The fish would take it in their mouths and then spew it out again. The men had a good laugh at their evident disgust at the uninviting repast.

J. P. Israel's piece is very amusing. We hope he will come again. We think C. C. Miller will have to hire a cheap boy to hunt out the especial items for him—one who does not care to read much, and would go by the headings. I suppose he finds the extras so interesting that he forgets all about what

he had been wanting. I read every thing in GLEANINGS, although I am not financially interested in bees, and am not very good friends with them any way; but even the bee-articles are so spicy that I would not miss them for a considerable. But I prefer the carp and chicken stories, and especially the Homes and comments.

Los Alamos, Cal.

AUNT KATIE.

Thank you, Aunt Katie, for the instruction you give in regard to keeping fish in the house. A friend was down to see our carp-pond a few days ago, who said that a carp-raiser made his wife a present of two little fish not larger than a cucumber seed. They fed the fish on small particles of oatmeal, and he said that they doubled in size in only three or four days. Such pets are not only amusing to the children, but they are instructive. You, my friend, have learned that fish can live in a glass jar without being fed, etc.; and it seems to me that all the knowledge we gain of this kind, by practical observation and experience, helps us along in the world. When poor Nancy was sick, oh how I did wish that I knew more about horses, that I might be able to give her at least a little intelligent relief from her sufferings! When the man who took care of her came into the stable in the morning, even though she was too nearly dead to notice any thing she looked at him and whinnied.

THE TROUBLE THEY HAD AT CHARLEY'S HOUSE.

WERE THE BEES ROBBING, OR WHAT WAS THE MATTER?

THIS has been a poor season for bees so far. It has been cold and rainy. Our principal honey-plants are white clover, basswood, poplar, locust, willow, maple, and buckeye. We can tell when our bees are working on buckeye, by the bright-red pollen they gather from it. Basswood is plentiful in our vicinity. Maples are numerous in the swamps. The bees gathered lots of maple pollen in the spring. Mustard, tansel, goldenrod, dandelion, and pennyroyal are also plentiful. Figwort grows wild in the woods. Last spring we saw the bees of one of our large colonies rushing in and out at a terrible rate. Supposing that a neighbor's bees had overpowered it, we shut it up, and to keep them from robbing our other colonies we shut them up also. Soon thousands of bees gathered over the hive we supposed was getting robbed, and a smaller number on the other hives. The day was a warm one, and late in the afternoon we opened the hives. The bees that were on the outside were gone. Now, what became of those bees? This is a question that I do not see into. The next morning all the bees went to work, and the swarm we thought was robbed soon filled their hive, made some surplus, then cast a fine large swarm. What were these bees doing that day? Could it be that they were taking honey from a beech-tree? and if we have any more such experience, what shall we do?

Our bees at present are working on white clover. We have the A B C book, and I like very much to read in it.

CHARLEY L. GREENFIELD, age 13.

Somerville, Ohio.

Friend Charley, your bees were out having

a playspell, and you are not the first one who has been misled in just that way, as you will see by the A B C book. When you shut up the hive, the young bees that had for the first time in their lives been out trying their wings were compelled to cluster outside of the hive; and after they had watched a sufficient length of time, and nobody came around to let them in, I suppose they went to other hives, probably attracted by the humming of the returning bees toward evening. The smaller number you saw on the hives not shut up were the young bees going to the hives because they could not get in at home. Young bees out on a playspell will usually be permitted to pass without hindrance into any hive, just as you would let a baby right into your house without any objection, if it should happen to wander away from its own home. If you watch carefully you can tell robbers from bees having a playspell, by noting their behavior. The playing bees dance up and down in the air, seemingly, and they also have a brighter look than old bees, being lighter colored on account of the soft down that covers them about the time they take their first outdoor flight.

TOBACCO AND SNUFF.

ALSO SOME FACTS ABOUT ANTS IN THE SOUTH.

SEEING you have not disdained to publish my little report, encourages me to appear before you again in a social sort of way. The letters in GLEANINGS, as a rule, are so homelike and chatty that one is naturally impelled to be sociable in adding to them. In reading them I frequently feel inclined to have my say-so on some of the points talked of; though as regards bees I would not venture, for I know as yet comparatively little of them.

Of tobacco, I may say that I am opposed to its use in any form or for any purpose. I would be a "prohibitionist" as regards it, if it would have the desired effect. If you had seen as much of the habit of "snuff-dipping" as I have been unfortunate enough to witness, you would not be able to say that our girls do not use it nowadays. Among a certain class of people South (generally mill and factory operatives), it is a common practice for the women to dip snuff; and many, many girls, even the little ones four and five years old, are brought up in the filthy, detestable habit. This, however, is a habit by no means confined to factory operatives; for many country girls become addicted to the use of the vile stuff; and seemingly it is as hard for them to give it up as it is for men to part from their dear tobacco-quids. In central Alabama I was astonished to find among a *nicer* class of ladies that the habit was practiced, though in justice to them I must say it was strenuously concealed whenever practicable, from all outsiders who would not "dip." You must know that the Southern factory operatives are as yet a different class of people from the New-Englanders of the same occupation. I have heard my grandmother (who is a Vermonter) say there is a vast difference. In course of time I trust the class down here known as "factory folks" will be on a par with the renowned "Lowell girls" of Massachusetts. As yet they constitute an illiterate, oily, "unwashed" class.

ANTS.

I hope you do not imagine that all over the South the bee-keeper has to fight against the ant. If you should be under that impression, let me disabuse your mind of it at once. There are many places never troubled with the industrious little nuisance, while some others are infested. For instance, we seldom see any here; yet about sixteen miles distant on our plantation one can scarcely look on the ground without seeing some running one way or another, and it is pitiful to see the little chickens following the mother hen and keeping up a constant dance, in order, if possible, to escape the bites of these little dark red ants.

I'll tell of an experiment of mine. I read once of the different kinds of stings that ants have—that is, some large red ones have a barbed sting like the point of a fish-hook, so that he is obliged to leave it in a substance too tough for him, as a bee does; but the common little ant merely bites. I thought it would be interesting to test the truth of the matter; so one afternoon I took a walk alone, to a red-ant hill whose location I well knew, and, seating myself beside it, I watched them awhile and then I carefully caught one and allowed him to run up my arm. Soon finding a spot to suit his purpose he inserted his sting a little below the elbow; and when he freed himself his sting remained, with a portion of the vitals, while the ant ran wildly about, then disappeared in the crowd, soon to perish, I suppose. I was satisfied fully of the truth of what I had read; but I was not content to let the ants alone. I caught and tried another with the same result; then more, until when I had finished I was the contented possessor of five stings on my arm. By this time my arm was itching, and was considerably inflamed. I walked home. When, by reason of the pain and itching, I could conceal my uneasiness no longer, I explained at the house what I had done, and was laughed at for trying such an experiment on myself. I went to my room, and was still suffering all the agonies the large red ant is capable of inflicting on a system rather susceptible to the effects of such poisons, and was in tears by now. I heard a voice calling me. "Bert! O Bert!" it called gently. My heart swelled; it was one of my brothers, and I thought, "Now I shall have some sympathy." I answered his call. This is what he said to me: "I say, Bert, had you not better send the result of your experiment to the New-York Entomological Society?" I "collapsed." I have never tried to investigate the different species of ant-stings since.

BERTIE NORRELL.

Augusta, Ga., June 21, 1885.

Friend Bertie, I am afraid you are a little severe on your neighbors who work in the factory. There are factories here in Ohio where drinking, swearing, and tobacco-using are the rule; and then, again, there are others where such things are not known at all. I believe that the boys and girls who work in our factory are considered quite as respectable and intelligent as any class of people we have; and I am inclined to think that it is becoming more and more customary with the proprietors of shops and factories to insist not only on temperance in the matter of drinking, but in the choice of language, etc. Of course, in many kinds of work it is not possible for the operatives to avoid dirt and grease; but this fact should never be considered a reason to look down

on them.—We are glad to hear of your experiment in regard to the ants, and the way in which they sting.

SUNDAY SWARMING.

GETTING A SWARM FROM A HIGH TREE.

ONE Sunday a large swarm of bees came out and settled very low upon a peach-tree limb. It stayed about two hours, and then started off toward the east. If it had been a week day we could have hived it. Before this, all swarms that came out on Sunday stayed till Monday; but this one did not, so we went to work next Monday morning with sad hearts. Pa went to work in the orchard, and sent my brothers and me to hoe in the garden, and told us when we got done to go where he was. Just as we got done in the garden at 11 o'clock, we heard a loud hum which sounded like bees passing over. Brother Finney ran out at the back of the watermelon patch, and found a large swarm of bees in the top of a high white-oak tree. Pa said it was almost too late for them to leave, and told us to work till twelve o'clock and then we could hive them. I was looking all the time for them to fly away, and I tell you I did not eat a very hearty dinner that day.

I was soon seen climbing up the tree, with some rope in my hand. The rope was made fast to the limb, then to the tree. Mother was at the foot of the tree, while my brothers cut. Pa was not in sight. When the limb was sawed off, the rope broke and the limb fell down, and there was a little scattering out at the root of the tree, especially among the younger boys. These words were often repeated: "Are they stinging you much?" No answer. After a while, "Are they stinging you much? Why don't you answer?"

At last it came. "I was shutting my mouth to keep the bees out. They are flying all over me, and stinging me on the head."

One of the boys was soon seen running toward the house, with one eye larger than the other. Finney kindly gave me the swarm. They settled on a smaller limb. I got another rope, then tied it to the limb and sawed it off and let it down and hived them, and they lived and did well.

After a while I sent \$3.00 for half a pound of bees and a queen; but when they arrived they were all dead but the queen and a few bees. I put them in a hive with a frame of brood, and next morning I went to see how they were getting along, but they were gone. On looking around I saw a few bees crawling in the grass, so I looked for the queen, but in vain. So I went to the house, feeling very sad—money gone and bees gone, and no money to send for any more. I guess you know how I felt.

About 11 A. M., mother said that the bees kept flying around the house and told me to look after them. When I looked, where do you think I found them? On the top of the house, under a board! We hived them and moved an old colony, and set the new one in its place, which made it a strong colony; so now I have three colonies of Italian bees, and all doing well.

B. J. TAPLEY.

Columbus, Miss.

Thank you, my friend, for your graphic and interesting letter; but it seems to me there would be no harm in hiving bees that settled upon a peach-tree limb, even if it

were Sunday. Of course, I should not want to go up into a tall tree with ropes, etc., on the Sabbath. The point you make, in regard to being sure that you have a rope that will not break, is a good one. I have heard of just such mishaps before. The foliage on a large limb is pretty heavy, and you want a good stout rope. If your half-pound of bees arrived mostly dead, the man who sent them to you certainly ought to credit you with their value; at least, that is the way we do business. You very properly went to work as well as you could to save the queen, so the shipper ought to feel grateful to you for saving him so much, even if the bees did die.

A SIMPLE DEVICE FOR EXCLUDING DRONES.

A DRONE-EXCLUDER MADE OF A SINGLE PIECE OF WOOD.

MAIL to you what I call a drone-excluding device. I think it ahead of Alley's in every way; handy to make, cheap, nothing to rust. Place it at the front of hive, tuck it so the drones can not move it, then see them come out of the tube. When they come back they alight on the hive, or at the entrance of hive. They will never find the place where they got out. Try it and see; if it is of any use to you or any other man, let him have it. You see, I trapped wild turkeys. This is the same, only the drones come out to be killed, while the turkeys went in. Bees are doing finely.

B. F. SPAFFORD.

Morning Sun, Iowa, July 27, 1885.

SPAFFORD'S DRONE-EXCLUDER.

The friends will notice that this device is made entirely of wood. The square tube is $1\frac{1}{4}$ x $\frac{1}{2}$ inch at the large end, and $\frac{1}{2}$ inch square at the small end. The hole is about $\frac{1}{2}$ inch square; but I presume a round hole, cut square and funnel shape at each end, would answer equally well. The arm projects 5 inches. A notch is cut in one side of this arm deep enough to let the worker-bees through, but exclude the drones. The device has to be placed over the entrance of the hive, and fastened so it can not be moved away. The worker-bees in going out can go through the tube or under the bar, as they choose. The drones, finding themselves unable to get under the bar, will gradually work along until they go out of the tube, and I can readily believe they will never think of going back the way they got out. These devices should be made at a price not to exceed 10 cents each. If wanted by mail the postage will be 5 cents extra. I should be glad to have friend S. tell us how long he has used this arrangement, and how it answers under all circumstances. I suppose we should have to have metal for the bee-space, if we expect to restrain the queen as well as the drones; but wood will answer perfectly well for drones only.

Every boy or girl, under 15 years of age, who writes a letter for this department, CONTAINING SOME VALUABLE FACT, NOT GENERALLY KNOWN, ON BEES OR OTHER MATTERS, will receive one of David Cook's excellent five-cent Sunday-school books. Many of these books contain the same matter that you find in Sunday-school books costing from \$1.00 to \$1.50. If you have had one or more books, give us the names that we may not send the same twice. We have now in stock six different books, as follows; viz.: *Sheep Off*, *The Giant-Killer*, *The Roby Family, Rescued from Egypt*, and *Ten Nights in a Bar-Room*. We have also *Our Homes, Part I*, and *Our Homes, Part II*. Besides the above books, you may have a photograph of our old home apiary, taken a great many years ago. In it is a picture of myself, Blue Eyes, and Caddy, and a glimpse of Ernest. We have also some pretty little colored pictures of birds, fruits, flowers, etc., suitable for framing. You can have your choice of any one of the above pictures or books for every letter that gives us some valuable piece of information.

"A chiel's amang ye takin' notes;
An' faith, he'll prent it."

WELL, little friends, it is now August, the month that usually furnishes us the dry hot weather. But it is not dry here at all; in fact, it rains almost every day, and the under-drains carry so much water into the carp-pond that it is full, and running-out at the outlet almost all the while. When the water rises so high that the carp can get up and nose around the grass on the bank, they enjoy it amazingly—especially when the water is very warm. The other morning I went down to the pond very early; and so many great big fish were busy at the roots of the grass along the bank that I thought perhaps I could catch one and carry it up to the house to surprise Huber and the rest of the family. I got down on my knees among the tall grass and weeds, and waited until a great big one came up right before me. The water was so muddy he could not see me at all, and I waited until his great shining back was right up between my two hands. I thought I would make real sure, and so I moved my hands down until they almost touched him, and then made a grab. Do you think I got him? Not a bit of it. I guess we both felt somewhat astonished. The minute one finger touched his back he made the biggest flop you ever heard of, and threw the water all over me, and was gone somewhere so quick that I couldn't tell how or where. Just then I heard a chuckle upon the fence; and, looking up, I saw a squirrel acting just as if he were holding his sides to keep from laughing. When I turned he started off along the top of the fence; but he made a sound as if he were chuckling still. I washed the muddy water out of my eyes, and went home just in time for breakfast, where I told my adventure; but I didn't have any great big fish to show them, as I had planned.

KIND WORDS FROM ONE OF OUR JUVENILES.

My papa keeps bees and thinks a great deal of his A B C book he got of you, and doesn't know how he got along without it, and also takes GLEANINGS. Mamma thinks a great deal of Our Homes in it. He has twelve stands of bees. Papa bought that nice queen you sent to Mr. Essick (as he found after sending to you that his bees had foul brood). Papa likes to deal with you, as you are so prompt.

Grand Ridge, Ill.

LIZZIE A. PARMLEE.

My papa had 20 swarms of bees last fall; five of them died in the winter. One of them lost their queen this spring. Papa gave them a comb with larvae in, but they would not build queen-cells. He looked two or three times, but could not find the old queen, so he put a weak swarm in with them, and now they are all right. Nearly all the bees died around here the past winter.

MARY WILLSON, age 9.

Newmarket, Ont., Can., June 4, 1885.

A FAVORABLE REPORT OF THE FOUNTAIN PUMPS AS A SWARM-ARRESTER.

We had a swarm of bees the other day, and they stayed on the tree about three hours, and then they started to go away. Mamma went and got the fountain pump, and threw the water up in front of them, and they thought it was raining, and they turned and came back and went on another tree to see if it was really raining. Then we got them and put them in a hive.

ALICE McBAINE.

Cokeville, Pa., June 5, 1885.

CROSS BEES, AND FLORA'S PROPOSED REMEDY.

Grandpapa says Mrs. Harrison need not kill her cross bees. Just make a false man and set it up before the cross bees, and let them have their fill stinging that. We have only one stand of hybrid bees, and they are as cross as the letter X. They will go four or five rods to sting a person.

Daisy, Kansas.

FLORA A. CONSTOCK.

Although I have never tried your plan, Flora, it does not seem to me as if I should want to do any thing that would make bees sting worse. My experience has been, that it is best to teach them to forget their stings as much as possible. By the way, I think I would apply the same treatment to little girls and boys. Have them taught in such a way that they will forget that they have the power to sting or hurt the feelings of anybody.

HOW TO TEACH FISH TO RING A BELL WHEN THEY ARE HUNGRY, ETC.

Pa has 14 stands of bees. He divides them in stead of letting them swarm. Pa is very much interested in carp culture. I read in a little paper pa has, that fish in Japan are taught to ring a bell when they get hungry. The way they learn to do it is to hang a silk cord in the water, with a little piece of bait on it. The fish then see that it is something to eat. They catch hold of it, and give it a jerk, which rings the bell. Pebbles are afterward tied to the cord. They will then catch hold of the pebbles when they get hungry, and thus ring the bell.

AMY J. HOLLEMAN.

Wager, Ark., June 1, 1885.

RASPBERRY-BLOSSOMS, CHICKENS, ETC.

The bees are working busily on the raspberry-blossoms and clover, especially the alsike. We have had ripe strawberries for two weeks. I hope

Huber has had some by this time. You seem to have had bad luck with your chickens. But if you had washed the eggs clean in luke-warm water they would have been as likely to hatch as at first. Of 90 little chickens hatched, we have lost but ten. Well, I will close by telling you that to put a swing up in or near the bee-yard is the way to get the children to watch the bees in swarming time. Papa always puts one up for us, and we like it pretty well.

ETHEL I. BEATTY, age 14.

Shaw's Landing, Pa., June 20, 1885.

HARD CIDER "HARD" ON BEES.

My brother-in-law lives about fifty yards from where we do. He had a barrel of vinegar sitting out in the yard making, with a cloth tied over it. His bees cut a hole in it, and they got drunk. They were stumbling about, and stinging and falling all over the place. This is the truth. Did you ever hear of bees getting drunk before? He covered it up, and the next day they were all right.

Collinsburg, La.

JOHNNIE DUDNEY.

Yes, friend Johnnie, I have heard of bees getting drunk before, but I have always been a little incredulous. Are you sure they did not get their wings daubed so they could not fly, that made them tumble about in the dirt? Bees are apt to do this when fed in the open air with any kind of a feeder, unless the honey or syrup is made very thin by adding water to it.

ABOUT THAT BEE-TREE.

My pa and uncle robbed four bee-trees this spring and we had some very fine honey and sold the bees-wax for 12½ cents a pound. We tried to save some bees from the trees, but could not; they would not go in the hives. My pa found a little oak this spring that had a swarm of bees lodged on it. He took his ax and cut the tree down and tried to save the bees but failed. He left the hive there all night, and in the morning the bees were all gone, so he brought the hive home. We have a great many wild flowers here, and some wild honey in the woods. I am anxious to learn about bee-raising, and if I can get the money I will take GLEANINGS, and try to raise bees. I love flowers and so do they. I have my window garden of flowers, and we are independent girls; we saw and nail our own flower-boxes, and put up the shelves, and I think we can make a hive.

SARAH L. MARTIN.

Bayou Chicot, La.

HOW WE HIVED A SWARM OF BEES.

One day last spring my father had gone away, and while he was away the bees swarmed. Well, I ran to the field after my cousin, who is about 20 years of age. He was working for my father. We did not think he would be of much help, because he was such a coward around bees. Well, they had alighted on a big limb—so big that we could not cut it off, because it would spoil the tree, so we spread a table-cloth on a stand, and then placed the hive on it under the bees. We dared not go up so close as to shake the limb, so my cousin took a long rope and went up to the limb very carefully, and tied the rope to it; then all of us—my sisters and brother, cousin, and myself—got hold of the rope about a rod from the limb, and then we would all jerk at the same time. Well, we managed to get a few of them off, but not enough to amount to any thing. My cousin got stung three or four times, and then he had his overcoat and mittens on, and a veil over

his face. I guess he must have sweat some, for it was a very warm day. Well, my sister Nettie plucked up courage and went up and shook them all off, and never got stung, and then we got them in the hive all right, and did not have any more trouble.

IYA A. PECK, age 12.

Jackson, Mich., June 3, 1885.

REPORT FROM A JUVENILE.

Our bees were gathering honey lively until bass-wood ended. The honey which the bees gathered so far is of the finest quality that we ever see or tasted—so white and sweet.

Ligonier, Ind.

A SUBSCRIBER'S SON.

NETTIE AND HER EDUCATED HEN.

I have an old hen, and her name is Mabel. She has 18 little chickens. I take her and set her on a box, and tell her to sing me a song, and she will begin and sing a few moments; and if she does not sing long enough I tell her to sing some more, and then she will sing until I tell her to stop. I keep Mabel and her chickens in a coop. One morning all of her chickens got out of the coop and went off in the pasture, and I went and got her and asked her if she knew where her chickens were, and she answered me in some language, I do not know what kind; so I took her out where her chickens were, and I asked her if she was glad I took her to her chicks, and she answered me. My old hen is a pure buff Cochins. There is a lady who engaged our eggs one year ahead, so as to be sure to get the pure buff Cochins. She takes all the eggs we have to sell. We keep about 30 hens. My brother keeps bees; he has three colonies.

Woodstock, O.

NETTIE CRANSTON, age 10.

WINTERING OUTDOORS WITHOUT ANY HIVE; A REPORT FROM ONE OF OUR JUVENILES.

Mrs. Mary Anderson, near Antrim, Guernsey Co., O., had a swarm of bees July 4th, 1881. They hived them in a new box. In an hour they came out and went back; but instead of going in they went under the bench and built combs extending from the bench to the ground, a distance of 12 inches, and 20 inches in width. They had no protection except a picket fence, and a few loose boards that stood on the west side to prevent the snow from blowing in on them. In this condition they wintered successfully while several other stands on the bench died. One of their neighbors, a Mr. Griffith, transferred them in the spring, and pronounced them good. They were the black, or brown bees. The lady who owned the bees lives about four miles from our house; and as it was something new to me about bees, I thought I would write it to you.

ANNA B. MCGREW, age 10.

Milnersville, O., July 8, 1885.

Friend Anna, there are a good many cases on record quite similar to yours; and I believe that a great many times our bees would winter all right if put under a bench, without any hive at all, where they now die by the hundreds and thousands. These cases point clearly to the fact that our bees are too closely packed up; that is, they do not have air enough; and such facts have come to light year after year for almost centuries. It is doubtless true, that they will do better with some protection than with no protection at all; but the protection ought to be in such shape that it permits air to pass freely, around and through the cluster of bees. A

chaff hive with the entrance open the full width in winter, as it is in summer, and loose leaves or loose chaff above the cluster, seems to me would be about the thing.

Pa has five swarms of bees, and one of them is an Italian swarm. He has log hives five feet long and 32 inches in diameter. They are hollow, and there are little doors in each end, and he takes the honey out of the little doors. I like honey. MILLY KEYSER.
Wilksport, Ont., Can.

I am twelve years old, but I must write about bees. Bees were introduced into America from Europe; they were first brought to South America in 1845, and California in 1850. The Indians called bees the white man's fly, because it followed where he went. EUGENE HOLZER.

Allerton, Iowa.

HEDDON PLAN OF AFTER-SWARMING.

Ma has 40 stands of bees. She lost eight stands last winter. She did not lose as many as the most of the people. It was very cold here. My ma takes GLEANINGS. She had only 21 stands in the spring, and now she has 40. Ma tried the Heddon plan, and did not have any after-swarms at all. I read GLEANINGS when there are letters in it. ANNIE COCHRAN.
Macon, Ill.

WHAT AILED THE BEES?

Papa bought several stands of bees, and the most of them died last summer. Could you tell what was the reason? ETTIE FARIS.
Huffman, Ala.

Friend Ettie, it is pretty hard to tell why the bees died in the summer time, without knowing more about the facts in the case. Perhaps they lost their queen, and dwindled away. I think the A B C book would help you to find out what the trouble was.

THE CALVES, THE DOG, AND THE SHEEP, AND THE WAY THEY MANAGED TO FIND NAMES FOR THEM AT JESSIE'S HOUSE.

My father takes GLEANINGS. We have an extractor that we bought of you several years ago. Brother has three calves, named Cleveland, Hendricks, and Tilden. Sammie has a little dog named Huber, and two sheep named Doolittle and Novice. I am one of six children, Baker, Fannie, Jessie, Ellie, Thomas, and Susie. JESSIE SMYLLIE.
Caseyville, Miss.

HOW TO HIVE A SWARM OF BEES, DESCRIBED BY ONE OF OUR JUVENILES.

My aunt Fanny keeps bees, and one day they swarmed, which is something I had never seen them do before. On my way to school I heard an awful noise, and I knew in a moment what it was. Then I ran into her house and shouted at the top of my voice, "Aunt Fanny, your bees have swarmed!" But I could not find her; so I ran over home and told mamma the whole story. She ran out to look at them, while I ran up the road to find my aunt Fanny. I saw a boy, and he said she was up at his house. After I ran up there and told her, she jumped and caught up her shawl and said, "What! have those bees swarmed again?"

"Yes," said I.

Then she told me to run down on the new road, and get my uncle William, who was cutting bean-poles, which I did. We got into the wagon and drove home as fast as we could. Then we fixed

the hive all ready beside the other hives, and then my uncle William took a saw and sawed off the limb upon which the bees had gathered, and placed it in front of the hive. Then my aunt Fanny sat down beside them and took a little branch off a pine-tree, and tickled the bees on their backs, and made them go into the hive. I lay down in front of the hive, and laughed to see them stand on their heads as they went in. HERBERT A. HODSDON.

Center Ossipee, N. H.

Friend Herbert, your description is real good; and I presume that, by the aid of it, one who had never hived a swarm would manage pretty fairly.

BEES THAT MAKE HONEY, BUT DON'T SWARM.

My brothers had a swarm of bees summer before last that swarmed six times, and went back to the hive every time. It died the next winter, and had a lot of honey left in the hives. What is the matter with a swarm that makes lots of honey and doesn't swarm? My brother has got a swarm of bees that have not swarmed for three years.

Douns, Ills.

Why, my little friend, I should say that nothing was the matter; but on the contrary, the bees are doing exactly what we want them to do. If you could advertise a race of bees that would make lots of honey, and would not swarm, you could make a mint of money.

450 SWARMS OF BEES IN SIX DIFFERENT APIARIES; REPORTED BY A 12-YEAR-OLD JUVENILE.

I have one swarm of bees, which was given to me by my pa. He has 450 swarms standing on six different places, which he works with the help of a hired boy. I have two brothers and two sisters, and we have to help pa in the summer, making foundation and extracting honey. Pa puts a lot of empty comb into empty bee-hives on the wagon, to carry them to the different places, and fetches back full ones; then we children have to put them in the extractor, and throw out the honey and put it in tin pails. I can not go to school just now, as we are very busy; but I am fond of books. My elder sister is 15 years of age, and is at work putting foundation in honey-boxes. My youngest brother is five years old. He is wasting a good lot of nails, and not much good yet. ELIZABETH HOFFMAN.

Canajoharie, N. Y., June 28, 1885.

Why, Elizabeth, your father is really putting in practice the plan I give in the A B C book. I notice your letter is dated where the *Bee-Keepers' Exchange* used to be published. I am glad to know that bee culture is flourishing to such an extent in the neighborhood of our old friend Nellis.—Never mind the nails your five-year-old brother is wasting. Although his work may not amount to much, driving nails helps to make the boy grow into a man; and if he learns to drive nails skillfully, the time and money won't be wasted. It was only yesterday that I saw two of our grown-up men driving nails, and they started the nail into the board in such a way that it acted like a wedge, and would be almost sure to split the board unless it were very tough and strong wood. I wonder how many boys and girls who read this know just how to set a nail when they commence to drive it. If you do not, get your father or brother to show you.

OUR HOMES.

Give, and it shall be given unto you.—LUKE 6: 38.

IN my talk to you to-day, my friends, I shall lay myself open to the charge of boasting of how good I am, as I have done many times before; but those who are acquainted with me understand what I mean, and will take me as I mean, but it might not sound so well to a stranger; therefore if any one reads this who has just subscribed for GLEANINGS, and does not know my way of teaching, he will please take notice.

Our friend Terry, in teaching us how to raise potatoes, feed horses and cattle, and other like farm operations, keeps telling continually what *he* did; and his statements are so much beyond what farmers usually do, that a great many are tempted to say they do not believe he is truthful. You can visit him, however, if you wish, and can inquire of his neighbors or hired help in regard to the statements he has made, and thereby satisfy yourself. Now, I have not any thing to tell, of how much money I have made, or of how much better I have done than other people; but I do like to tell how I have succeeded, assisted by the teachings of the Bible, in getting along very pleasantly with the world, and in having a very pleasant and joyous life myself.

The words of my text came to my mind this morning while we were discussing celery. We have for the first time succeeded in getting a good crop, some of it ready for market in July, and it is selling quite readily at five cents a stalk. A stalk of the White Plume, and another one of the Crimson Dwarf for contrast, were in a glass while we were talking. One of the family remarked, that the boys all over town were going into celery, and that they would soon run the business all out, for they were getting just as nice stalks as I did, if not nicer. Another member of the family made the remark, "That is just what he wants them to do—and, in fact, is just the way he has worked all his life." I presume that the speaker meant that I always delight in teaching people how to do things, especially young people; and that, when my pupils become more expert than their master, I am always happy. I have been thinking it over, dear friends, and I think it is true. I do not wish you to give me any great credit for it, for it seems an easy thing since I have become a Christian. You know I have no patents on any thing I have ever originated, nor do I want any. Visitors often express surprise, and say they should think that I would need some protection. My reply is, that I am glad to have people copy any thing I make; and if they have facilities for making it cheaper than I can, I ought to be pleased because the world at large will be benefited by lower prices. But some of my intimate friends declare that if I had my improvements patented, and would monopolize the sale of them, I could be worth thousands of dollars more than I am now.

Now, then, friends, remember the caution I gave you in the first paragraph of this talk,

when I say, "I do not want to be worth thousands of dollars more than I am now." I do not make this speech in the presence of strangers, or of those whom I think would not understand me, for it would be met with derision, and may be sarcasm. Some whose eyes fall upon these lines may say, "Mr. Root, if you do not want to be worth any more than you now are, why do you stick and hang for every penny, in the way you do, and persistently keep dunning those who owe you, with such fierceness?" My reply would be, that I try to collect all my just dues, because I believe it is better for the one who owes to pay it, rather than to be excused from paying it; and I have come to this conclusion after years of experience. Yes, I believe it is better for a poor widow to pay her just debts than to be excused from paying them. If widows or other people who have been unfortunate by reason of sickness or death, or other ways, need assistance they should have it, and I believe our townspeople are well aware that I am ready to subscribe liberally; but I think such subscriptions should be a separate matter from the debt. My experience has been, that there is something demoralizing in excusing a person, whether a woman or man, from paying what he justly owes. If a poor family were owing me five dollars, I should insist upon the payment, if there were a reasonable prospect that they could pay it; but if a subscription were started in order that they might have a house built, so as to avoid paying rent, I should enjoy subscribing *ten dollars* for the purpose, or even more, if the case seemed to demand it.

Now, then, in regard to the promise, "Give, and it shall be given unto you." People often urge, that, if we are not protected by a patent, the unscrupulous world will rush right in and steal every thing, may be leaving the inventor penniless. I have heard of such cases, friends, but they have never come under my own experience; that is, I have heard people declare they were the authors of great inventions, but that unscrupulous men of means had robbed them. I have never come across such a case that I know of. On the contrary, my experience has been, that, where a man has been willing to give freely all the knowledge or information he possessed, in some way or other new things were continually opening up to him. In the past two or three years a good many have started in the supply business, making and dealing in bee-hives and fixtures. I have been asked if I was not afraid that so many would go into it that it would be overdone, and our large factory would be standing idle. I have not had any such fear, but, on the contrary, I have enjoyed the work of furnishing these tools and implements for running opposition to us. I have delighted in having the friends visit our factory, and witness the manner in which we make hives, comb foundation, sections, etc. I have been glad in seeing them take measurements, that they might build machinery like our own. One reason why I was glad to see them do it was because it saved heavy freight shipments on such heavy goods as hives and sections. We are now

getting five cents a stalk for our celery, as I have told you. Some extra fine stalks have brought as high as ten cents each. With the prospect that all the boys will go into it another season, the prices will go away down. Never mind; then many people will be able to afford this luxury, who can not enjoy it now. New things have opened up to me all my life, and I have no fear but that they will be opening up still.

A few months ago there was a talk among bee-keepers that Cuba was going to furnish nice honey so cheaply that, if it were permitted to come to the United States free of duty, nice honey would come down to six or seven cents a pound, and our bee-keepers would be compelled to give up the business, and would become bankrupt. Now, I did not look at it that way at all. When it was announced that Cuba could furnish such amounts of honey by means of modern appliances, I felt a thrill of pleasure in thinking that honey would then be able to compete successfully with sugar, and that many poor people could enjoy it every day who could not afford it at present. And while I am about it, I do not believe in duties between countries. I do not know any thing about the political aspects of the matter, but I would have nations as neighborly as individuals, and it seems to me to be a grave mistake when we put up a barrier, in the way of duties and customs. When Jesus spoke the words at the head of our chapter, he had been talking quite a little time to his followers about the evils of jealousy, covetousness, and selfishness. He said, "Love your enemies, and do good to them that hate you." Now, it seems to me that in this matter of duties we are afraid to do good to those who are *friends*, to say nothing of enemies. "If ye do good to them who do good to you, what thank have ye?" And again, "If ye lend to them of whom ye hope to receive, what thank have ye?" What an unpleasant thing it is to be always worrying, for fear somebody will get ahead of us, or for fear somebody will get the better end of the bargain! Only yesterday, I, with a neighbor, bought a carload of water-melons. Some suggested the proper way was to have two divide them—one pick the best melon, then the other pick the best melon, and so on until the carload was exhausted. We managed in that way, but I objected on account of the time it took. The time occupied was in making careful selection, so that the man who was working for me might not let his opponent get the better end of the bargain. I proposed that each should take a melon, as near alike as they could get them, by picking them up about as fast as they could handle them. Very likely the division might not be as exact, if we did it this way. Well, suppose it were not. My neighbor would have a little better half than I did, or I should have a little better half than he did; and providing it were impossible to divide them exactly, I should prefer that he have the better half, and I have do doubt he would prefer that I should have the better half. Then why so much anxiety and so much pains?

Since Nancy has died, I am under the nec-

essity of buying another horse. My first impression that was at all pleasant, in regard to her death, was, that I could probably purchase a horse of somebody who needed the money badly, and thus do him a favor. I like to pay people money; don't you?—especially when I have an opportunity of noticing the good use that is made of it. A few days ago one of our men wanted me to come and see his garden. He was not at home when I chanced to have a spare moment, but I went all over his little place. I looked at all his vegetables, and admired his pretty lawn. I took in at a glance the work his good wife had done also, in making the home pleasant, and the thought that the money that I had paid him for years every Saturday night had been used in this way, gave me a thrill of pleasure. I know he loves his home, and I know he thanks God for it.

Now, in regard to purchasing a horse, somebody suggested that farmers would ask more for their horses if they found I wanted one, because they know I pay liberally. Well, suppose I do give some young hard-working farmer a good price for the horse he has taken great pains to rear and train. What harm will it do? You may say, "Why, friend Root, you will run through all the property you have, if you pay big prices for every thing, just because you like to see people pleased with a big price." To which I reply, I shall not do any thing of the sort. People have prophesied that nobody could ever stand the ways in which I "throw away my money" ever since I became a Christian. But I have not become poor, nor got into debt. It is true, I am paying interest on four or five thousand borrowed money, and I have been paying interest almost all my life. A good deal of the interest goes to my employes, who have left their hard earnings with me, and I enjoy the fun of paying the interest. The book-keeper has positive orders to pay it annually, whether they call for it or not; and if they do not want it, the interest is allowed to compound. Sometimes she argues that there is no need of giving people compound interest, when they would be perfectly satisfied with simple interest. Now, I think that compound interest is all right. When I keep anybody's money, providing I need it, I want to pay them for the use of it, just as much as I would pay a man for the use of a horse when I use the horse every day. Some widows of our town have left their money with me. They get no interest at the bank, and it affords me a real pleasure to make investments so I can afford to take their money and pay them interest for it. Do you say again, that I shall break up if I keep going on in that way? People who do not know me have said so ever since I became a Christian, but they have been mistaken. What does the little text say, at the head of our chapter? I have not quoted it many times, but I have had it in mind all through my talk.

I like to buy queens of the friends in the South; I like to send them orders for "great big lots" of them. And then I like to see postal cards where the book-keeper tells them, "The above amount is subject to your

order whenever you choose to call for it." Then I like, too, to see the friends call for it, and I love to show them how quickly we can speed a check on New York, in answer to these requests. I tell you, friends, it is rare fun to do business—yes, lots of business, when you have the money ready to meet every payment or every demand just as soon as the call comes. No doubt you agree with me; but perhaps you ask, "But, where shall we get this inexhaustible bank account, or balance on the bank, subject to order?" Why, bless your heart, dear brother or sister, read the text, and now read this promise:

But seek ye first the kingdom of God, and his righteousness; and all these things shall be added unto you.—MATT. 6:33.

If all your business arrangements are managed with the sole thought in your mind of doing good to your fellow-men, or, in other words, working for the Savior's glory, God will send the means and whatever else you need. Do you ask if I have ever been cramped for money? Yes, many and many a time, and many and many a time have I prayed, as many of the older friends know, for the means to do that which seemed right, and I believe that God always sent it whenever he could do so, and not have it harm me. A great many of my plans and experiments have been made just to discover something whereby I could keep the friends at work who were faithful, and wanted work; and whenever the motive has been purely to help my fellow-men, and not to get riches and honor for myself, God has sent the means. A good many times I am off the track. Sometimes for days together it seems as if I had strayed away from my Savior, and as if selfish feelings and ends would get uppermost. Then, of course, God could not consistently send me means. The first commandment reads, "Thou shalt not have other gods before me." When I keep in line with that, I am happy and thriving and prosperous. When something else gets before God, and I become selfish, I get to dwelling on narrow and contracted ideas—envy, jealousy, etc. (for I tell you, I know all about these things), then God withholds his promises, and I thank him for so doing.

I am vehement in collecting what is due me, whether I have money in the bank or not; although it is true, that sometimes, when we are in urgent need of money, I mention the fact to the friends who are owing me. I can illustrate the point I wish to make, by a little incident of the morning. Huber was playing near a large basket of beautiful red Astrakhan apples. His mother did not wish him to eat them, for very good reasons; and when I saw him chewing something, I looked; but the apples in the basket were all sound and whole, and he had none in his hand. Again and again I saw him eating, but it was apparently something else besides the apples. Pretty soon I looked over my shoulder, and saw him taking a great bite slyly, after which he crowded the apple away down under the others. For the first time in his life he was caught in the act of deceiving his papa. I fished the apple out of its hiding-place. In his guilty haste he had got hold of one that was rotten,

and had got his mouth full, and some on his nose; but, worst of all, *Satan* was making an entrance to his little heart, and, baby as he is, he showed his guilt in his downcast eyes. His papa gave him a little sermon, adapted to his limited vocabulary and intelligence. Did I take all this pains, and stop my work, and "make such a harangue," as some might have called it, just because of the value of a miserable little snarled specimen of an apple, and half rotten at that? Why, bless you, no. I did not care how many apples he ate, and I would have given him a basket full, or a wagon-load, in an instant, had I been sure they would have contributed to his best good and highest happiness. They were withheld because they were not good for him; and yet one who did not know me, nor understand the circumstances, might have called me little, stingy, and selfish. An hour later a poor specimen of humanity called at the back door, and wanted to know if I would give a poor man a bite of breakfast. I told him that the laws of the State of Ohio made it a crime for him to go around from house to house, making such a request. He at once replied that I was a pretty specimen of a Christian if I could not give a simple breakfast, with such an establishment as I seemed to be master of. I told him that he seemed to be able bodied, and capable of working, and that I would find him work at once, if he would do it, and find him a breakfast too. He glanced up, and then declared that he was not going to work unless he could have some kind of *decent* wages. He preferred to beg, if he could not make his own terms in regard to his services. Do you not see, friends, that the promise at the head of this chapter refers to none of these things?

In all your intercourse with your fellow-men, give good measure. This noon, one of the girls was going to send away some soiled bee-feeders. Christian people ought to give good measure and clean measure. I thought so then and think so still. Give a good clear equivalent for all you receive. Be careful and faithful, and make it your effort to please those whom you serve, and God will, in his turn, give to you good measure, pressed down, and shaken together; for I assure you that the great Father above is not short-handed when he makes good his promises. Try him and see.

I believe I have mentioned before, my experience with a brother-jeweler, while in the jewelry business, at the time of my conversion. We had been having a newspaper controversy, and I had occupied column after column in our county paper, telling the people how good and how smart I was, and how bad and how unfortunate my brother-jeweler was. We paid for these newspaper notices at so much a line, both of us, and threw away our money that way, besides throwing it away in selling things at a less price than they could be afforded. Does a Christian ever get into such jangles? If he does, it seems to me his Christianity is rather weak. Well, after my conversion, customers who wanted to buy articles of some value would go first to one store and then the other. One rainy day, when trade was

dull, somebody wanted a piece of plated ware, worth ten or fifteen dollars; and in order to get me to lower my price, the customer mentioned the fact that Mr. W. had a beautiful one that he had offered so and so. What should I do? What *ought* a Christian to do? I prayed God to show me, and the still small voice said, "Do good to those that hate you." Mr. W. doubtless hated me, because I had tried to injure him, and had tried to get away his custom, and break down his trade in every way I could. I will tell you what I did. I told the friend who wanted the article that it was not unlikely that Mr. W. had got something nicer than I had, and perhaps he had succeeded in getting it cheaper than I had bought my goods, and that I was quite willing she should trade with him, for he was a young man just starting in business, and that I should be glad to see him get along well. The lady looked up in astonishment. I assured her, by a pleasant look, that I really meant it, and by my advice she bought her goods of my neighbor. Do you think I felt bad because I had lost quite a sale? Not at all. God sent into my heart a flood of peace and happiness that was worth more than all the money I ever received in all my life for *any* goods, and I kept it up day after day, until my neighbor finally concluded that true religion was something worth having. And God crowned it all by enabling me to lead this man to the feet of the Savior; and one evening, after we had had a long talk, I had the pleasure of calling upon our pastor to kneel in prayer with the two jewelers of the town, who had, only one year before, been such bitter enemies that it was the talk of the county. Did my business suffer meanwhile? Why, bless you, no. No man's business *ever* suffered because he took a *friendly* interest in the business of his rival, and delighted in turning trade into his hands. I have not kept up that spirit all through my religious life, dear friends; but if I had, I should be a happier man than I am now, and very likely I should have been a richer man in dollars and cents.

Since newspaper controversies are up, I want to say a word here. A great many bee-journals have been started, and those who have started them have no doubt been very anxious to have them a paying investment. Now, it is the most natural thing in the world for an old-established journal to feel that no more journals are needed in the same line of work; and we should have to be almost more than human if we did not at times give way, at least just a little, to a feeling of jealousy. I have had to pray over this a good deal; but I think I am clear over selfish feelings there now, and I am sure I rejoice to see other journals improve, and originate new features that I never thought of. I am not afraid now that I shall not be able to smile and look happy when somebody tells me that he takes some other bee-journal than my own; and it does not hurt me any — at least I think it does not — to have some one make the remark in my presence, that some other bee-journal contains all that is worth reading. Of course, I do not quite agree with him; but then,

you know we have different opinions and "notions," and I don't believe that I want to see any editor of a bee-journal hurt himself by some unwise course. Why, to be sure, I do not. I feel ashamed of myself when I think of the feelings that I have sometimes entertained. If the other journals speak slightly or sneeringly of GLEANINGS, and some of the queer ways in which it is managed, I try not to feel hard toward them for their unkindness, and I almost always succeed. Suppose you read that sixth chapter of Luke, from the 27th verse to the end of the chapter. What a happy world this would be, if all tried to follow that chapter!

A great many who read these pages may be poor in this world's goods, and feel like saying that, if they had a store and plenty of money, such a course would be easy. But, how about those who work hard every day, and can just make both ends meet? How shall they give, when they have not any thing to give? You are mistaken, my friend. You *have* something to give. Everybody has something to give, and does give it. Sometimes they give it grudgingly, I know; but it is given, for all that. If you are working by the day, you give your employer your strength and your good will — at least, you *ought* to give your good will; but I am afraid that some who work for wages do not. If so, they are the sufferers. If your employer is hard and exacting and unreasonable, soften him and Christianize him in the way I did my brother-jeweler.

There seems to be one thing that the laboring-classes, many of them, do not understand. It is this: There is, the world over, a continual demand; and an unsatisfied demand, for faithful service—for cheerful good will. It is not strength we want. Strength of muscle is cheap; there is plenty of it. Strength of muscle we find among the men who shovel gravel on the railroads; but too often we find it without the good will accompanying. I once knew a widow woman with quite a family of children, who would not listen to the advice of her friends, to put her children out. She wanted to keep them all together, and she wanted to provide for them without outside assistance. Her strength was not great, and she tasked it to the uttermost, and then felt she was not equal to the task. What should she do? In a little time the neighborhood discovered that she was faithful to any thing intrusted to her care — more faithful than the ordinary help that could be employed. In whatever she did, whether it paid or not, she was in the habit of insisting on strict fairness and honesty; she could not be induced to be a party to any little petty fraud; and most people who employ hired help for housework know that little petty frauds are common. In other words, she did her work as if she felt that the all-seeing Eye was on her, and it was him she feared, and not man.

One has to be faithful quite a little time, sometimes, before God's promise comes, and it was so in her case. But it did not take long before she became known and appreciated, and she had plenty to do, and at prices

that would enable her to keep her little family all together, educate them, and bring them up in the fear of the Lord. This is what Jesus meant when he said, "Give, and it shall be given to you." You know he told us that, after our duty to God, is our duty to our fellow-men; and it has seemed to me all my life that a great blessing was following every man or woman who delighted in seeing others prosper, and who find no greater pleasure than in studying and devising ways and means by which they might confer favors on their fellow-men.

Now, dear friends, I have talked to you today in regard to the importance of loving your neighbors; for love must be the inspiring motive, or it can not be done. You must have such a love for the friends round about you that what you give will be given through love, or as the outcome of love, and love will often prompt withholding. I refused to let Huber have even one red Astrakhan apple out of a great basket full, because I loved him, and I did not want to see him sick. If you love your neighbor, that love will prompt you just exactly what to do about giving. If you hate him, and are all the while saying sneering things about him, and encourage the family to talk over his weaknesses and inconsistencies, you are away off from the track; and while you are in that attitude and frame of mind, your giving amounts to nothing. You can not put on this Christian spirit. There is only one way, and that way is the straight and narrow path. It begins at the feet of the Savior. You must get clear down low at his feet before this can come natural or easy to you. He told his disciples one day when they were talking the matter over, that anybody who came in any other way was a thief and a robber. See the tenth chapter of John. Now, then, when you are tempted to be selfish, remember God's words, "Give, and it shall be given unto you." And remember, too, that your old friend told you how to manage so you could do it, and be happy over it, no matter where or who you are.

TOBACCO COLUMN.

FROM ONE WHO HAS USED TOBACCO FOR 15 YEARS.

I HAVE been using tobacco for 15 years, but have resolved to not use it again. I have not used any for eight months; and if you think me worthy of a smoker, send it by mail; and if I ever touch it again I will pay you for it, and pay postage too.

J. M. RITTER.

Clapper, Mo.

I have 5 stands of bees, and I need a smoker very much. I smoke a cigar once in a while, but I would quit for a smoker, and promise to pay you for it if I ever smoke again. You say you want a person to say he will never use tobacco any more. I will say that, and stick to it; if I don't, I will register your pay for it.

P. P. CYRUS.

Staley, Ky.

DYSPEPSIA AND TOBACCO.

I like to deal with men who try to abandon the use of tobacco, and therefore I will inclose you one

dollar for GLEANINGS. I have used tobacco for the last five years, and it will be 100 years before I use it again. I see that you will send any man a smoker, who will try to quit the use of tobacco. Please send me one, and I shall be very much obliged for it; and if I use the poisonous stuff again I will pay you for the smoker. Now, my dear friends, all of you who read GLEANINGS, bear this in mind—that I was very sick from the above-named poisonous weed. I had had dyspepsia for nearly fourteen months when I quit the use of tobacco, but I got my perfect health again.

Alabaster, Mich.

WILLIAM KOHN.

I have resolved to quit tobacco, and I think that your gift will help me to quit that ugly habit; and if I ever use tobacco any more, I will at once send you the money for it; but I don't think I shall ever take it up again.

JAMES R. ELMORE.

Horn Lake, Miss.

I have been a reader of GLEANINGS for some time; and as I was a tobacco-user I was induced to quit by reading GLEANINGS. If you think I deserve a smoker, send it; and if ever I use tobacco again I will pay you double the price of the smoker.

Swander's Crossing, O.

JOHN H. DEWLESE.

FRIEND HUBBARD MAKES A FINAL DECISION.

I have often thought I would quit the use of tobacco, and now I have fully made up my mind to do so; and when I commence to use it again I will send you one dollar to pay for the smoker.

Oil City, Wis.

E. HUBBARD.

A MUTUAL AGREEMENT OF TWO NEIGHBORS TO DISCONTINUE THE USE OF TOBACCO.

Myself and one of my neighbors quit using tobacco on Easter Sunday, and I notice in GLEANINGS you give a smoker to those who quit. Now, we want you to send on the smokers, and if we commence using the weed again we will pay for the smokers.

F. P. HISH.

Henton, Ill., June 18, 1885.

I have been keeping bees about two years; and believing smoking to be an adjunct to beekeeping, I contracted the habit; but I found it hurting me, and told my wife I was smoking my last paper, and then I was done. But she doubted it; but seeing your offer strengthened my resolution. Though I can't say for certain, yet I will try; and if I fail to keep my resolution you will get your pay, or smoker will be returned.

S. DANIELS.

Pine Grove, Ohio.

Your generous favor (a bee smoker) came to hand a week ago to-day. It is a "dusky" smoker, I assure you. I never knew what to expect of a smoker before, but I know one thing—that if there were no better one in existence than the old smoker I had, I would have to invent one. But, friend Root, how can you afford to give them away, to hire men to not injure themselves? or is it none of my business? You do not even exact the postage, which was 19 cents on mine, or 17 more than I sent you, as I sent a stamp, thinking my letter would probably necessitate a private reply. I acknowledge I am a thousand times obliged for your generous confidence, and not that I have any desire to break my pledge. I will send you your money if you will tell me how much to send, as I am not willing to take any thing for nothing, and I hope you will find but few bee-men any other way disposed.

Pine Grove, O.

S. DANIELS.

Thank you, friend D.: but I don't want any more money, unless you go back to tobacco again, then you can send me the 70 cts. If I can see the friends giving up tobacco and other bad habits, it will be pay enough, and God will take care of the postage-stamps.

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

A. I. ROOT,
EDITOR AND PUBLISHER.
MEDINA, O.

TERMS: \$1.00 PER YEAR, POSTPAID.

For Clothing Rates, See First Page of Reading Matter.

MEDINA, AUG. 15, 1885.

For with the same measure that ye mete withal it shall be measured to you again.—LUKE 6: 38.

SECOND-QUALITY SECTIONS.

We have in stock about 10,000, just as good as our best in every respect, except that the color is a little off. We will sell these at half price as long as they last.

SPAFFORD'S DRONE-TRAP.

SINCE our article on another page in regard to this little implement was written, our apiarist gives notice that it works like a "charm." The drones are all found outside in a cluster the next morning after it has been used. We can furnish them at the prices given under the illustration.

OUR LAWN-MOWER FOR BEE-KEEPERS.

SO much of a trade has sprung up in these that we are enabled to reduce the price to an even \$6.00, instead of \$6.50. It is, perhaps, the best lawn-mower made, for cutting grass when it gets to be four or five inches high; and during a damp season, like the present one, such a machine is quite desirable.

INTRODUCING NEWLY HATCHED QUEENS, ETC.

ON page 562, friend Ellison gives a report in regard to introducing virgin queens. His success was just about what I should expect it to be with queens newly hatched. With those several days old he did better than I should expect. I believe the general experience has been, that newly hatched queens can be let loose into any hive that has been queenless for 24 hours or more, almost without a failure.

SENSE AND NONSENSE: SIFTING ONE FROM THE OTHER.

OUR good friends of the *Ohio Farmer* pleasantly take GLEANINGS to task for being devoted exclusively to bees and honey, and yet discussing whether arnica is good for sprains or not. If the editor of the *Ohio Farmer* read our whole article through he will notice that I had been speaking of the application of remedies in the shape of medicines for bee-stings. Well, I believe that nearly every old bee-keeper now agrees that the various stuffs that have been so emphatically declared a perfect remedy for stings have all been proved to amount to just nothing at all; and I "sort o'" asked the question, if it was not possible that our remedies for sprains and other like mishaps had as much to do with relieving the suffering, and no more. May be arnica

is good; but, would not water as hot as the patient can bear it be equally good, or possibly better?

MAMMOTH CAVE; FRIEND HOLMES TELLS US SOMETHING ABOUT HOW TO GET THERE.

SINCE my articles on the Mammoth Cave appeared, several have asked the question as to the best way, cost of getting there, etc.; and Mr. Holmes has kindly furnished me the following. If you will write to him where you live, he will probably tell you about what the expense of the trip will be.

Mammoth Cave, Kentucky, is eight miles from Cave City station, which is 195 miles south of Cincinnati, and 85 miles south of Louisville, on the main line of the Louisville & Nashville Railroad, which is one of the great trunk lines from all points north to Florida, and from the North and East to Texas, Mexico, Arizona, and California; and passengers purchasing their tickets over the Louisville & Nashville railroad, by notifying the conductor after leaving Louisville, can stop at Cave City to visit Mammoth Cave, within the limit of their tickets. Parties desiring to visit the cave can make arrangements for so doing by writing to General Passenger Agent, Louisville & Nashville Railroad, Louisville, Ky., or Herman Holmes, Traveling Passenger Agent, Medina, Ohio.

ADVERTISEMENTS THAT DO NOT PAY.

SOMETIMES an advertiser writes that his advertisement has not brought him a single application. Now, although we are very sorry to know that any investment of this kind has not been a paying one, we can in no wise be responsible for the result of such ventures. We sell you the space in our advertising columns, and arrange it so as to make the best appearance possible for each of our advertisers; but the result must rest with the one who gives the order. Perhaps some suggestions in regard to advertising may help you. When the season is comparatively over for untested queens, and everybody wants to sell, a good many will put in an advertisement. At such times it may meet with no response, where the same advertisement, put in in April or May, would flood the advertiser with orders. Again, people are a little slow in sending their money to a new man. A trade in any commodity must be built up by degrees, as a general thing, and it is only human nature to prefer to wait until your card has been standing for some time in the advertising pages, before sending an order. People prefer to get acquainted, as it were; but after they once discover you are prompt, and that you furnish all or more than what you agree to, your advertisements will meet with a quick and bountiful harvest, providing, of course, your prices are fair, and that you come before the public at a season when your goods are in demand.

BEE-KEEPERS WHO MAKE A BUSINESS OF GETTING TRUSTED FOR SUPPLIES WHICH THEY NEVER INTEND TO PAY FOR.

A PAPER on this subject has just been sent us for publication. The writer states that there are men who get trusted one year to A, the next year to B, the next to C, and so on, without ever paying any of their bills; and the proposition is made, that the names of such men be published. I am glad to see that this class of individuals seldom go into bee culture very much; but I do feel that there are enough of them so that the names of one or more of them should be kept constantly before the public, as a warning. Before doing this, however, we will notify the parties, and ask them what they have to say in regard to the course they have pursued. Another thing, I do not believe it is right for supply-deal-

ers to trust men whom they do not know. Insist on having a reference from the station agent, postmaster, or banker, before you fill any man's order without the cash, unless you know something about him; or inclose a postal card to us, and we will tell you, without charge, whom you can trust and whom you can not, as a general thing, for we have records of almost every man who has asked for credit for things pertaining to the bee or honey business. It is a part of the duty of bee-journals, without question, to save their patrons from losses of this kind.

REPORTS ENCOURAGING.

AS the honey season is over with us I will report my success. I started in the spring with three weak swarms and two fair ones; increased to 14 by natural swarming, and have extracted 500 lbs. of white-clover honey; have 100 lbs. yet in the combs, also 50 lbs. section-box honey. Basswood did not yield as much honey as we anticipated, as it did not last over four days. White clover came about June 1st, and lasted until the latter part of July. M. W. SHEPHERD.

Rochester, Ohio, Aug. 5, 1885.

Bees are now doing very well. We are getting 45 cents per pound for comb honey.

GEORGE B. McARTHUR.
Pickering, Mo., Aug. 7, 1885.

I report a very good season. I think I shall get 7500 lbs. from 100 swarms, spring count, mostly blacks. I lost one in wintering.

E. L. SWACKHAMER.
Schenevus, N. Y., Aug. 10, 1885.

Our bees have exceeded our brightest expectations. Some of the hives, which are only wild swarms, have completely filled their hives in a week or two; so if it were not for taking cards of honey and brood to feed in other young hives, and, together with the cutting-out of combs and all, I don't know what we should do with our honey.

A. P. GIBSON.
Church Hill, Jeff. Co., Miss., June 28, 1885.

CONVENTION NOTICES.

The Western N. Y. and Northern Pennsylvania Bee-Keepers' Convention is to be held at Salamanca, N. Y., Sept. 1 and 2d, 1885.

Janestown, N. Y. A. D. JACOB, Sec.

The Mahoning-Valley Bee-Keepers' Association meets at Newton Falls, O., Aug. 20, 1885.

E. W. TURNER, Sec.

The best Queens out.

I will furnish queens from July 1 to September 1 for one dollar; warranted tested, \$2.00; after then the price will be the same as in A. I. Root's list. Queens all bred from an imported mother.

16tfdb **G. F. SMITH,**
Bald Mt., Lackawanna Co., Pa.

DADANT'S FOUNDATION FACTORY, WHOLESALE AND RETAIL.
See advertisement in another column. 3btfdb

For Sale. Six full colonies of bees in L. hives, on frames of wired foundation, \$6.00 each. They are strong, and have black and hybrid queens. I guarantee safe arrival.

IRA D. ALDERMAN, TAYLOR BRIDGE, SAMPSON CO., N. C.

Red-Clover Queens by Return Mail.

I am now up with my orders, and can send queens by return mail. My queens are almost without an exception purely mated, and my bees worked just thick on red clover from the time it bloomed until the present.

15tfdb **J. T. WILSON,**
NICHOLASVILLE, KY.

IF YOU WANT

A GOOD ONE-PIECE SECTION CHEAP

Send to us. Sample and Price List Free.

VANDERVORT

COMB FOUNDATION MILLS.

Send for samples and reduced price list.

2tfdb JNO. VANDERVORT, Laceyville, Pa.

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they want to dispose of, we will insert notices free of charge, as below. We do this because there is hardly value enough to these queens to pay for buying them up and keeping them in stock, and yet it is sometimes quite an accommodation to those who can not afford higher priced ones.

I have 8 or 10 hybrid queens I will sell at 25 cents each. FRANK BAKER, Oakley, Macon Co., Ill.

I have 3 hybrid queens at 35c each, or the 3 for one dollar, by mail. W. A. COMPTON, Lynnville, Tenn.

A few good black and hybrid queens, at 15 and 25 cts. Kanawha-Valley Apiary, St. Albans, W. Va.

I have two black queens for sale at 25c each, or the two for 40 cents.

L. W. GRAY, Troy, Orange Co., Fla.

I have a few good laying hybrid queens for sale, at 50 cents each; blacks, 25 cents.

D. B. FLERY, New Carlisle, O.

I have a few hybrids I would dispose of for 30 cts. each; black queens 20c.

JOHN H. MARTIN, Hartford, Wash. Co., N. Y.

I have four young Italian queens, with clipped wings, that I will sell for 75 cts. each.

MARIA L. DEMING, Watertown, Wash. Co., Ohio.

Hybrid queens, 50 cts. each; black queens, 25 cts. each; from Aug. 1st to Oct. 1st, safe arrival guaranteed. G. D. RADENBUSH, Reading, Berks Co., Pa.

I have a few hybrid queens—some daughters of imported mother, for which I will take 35 cents a piece. W. A. KIRTLAN, Salem, Col. Co., Ohio.

I have about 50 hybrid queens which I will mail for 50c each; 5 for \$2.00. These are '85 queens.

B. T. BLEASDALE, 596 Woodland Ave., Cleveland, O.

Five fine large yellow hybrid queens, two months old, bred from pure Italian mothers, at 40c each, and guarantee safe arrival.

CHAS. McCCLAVE, New London, Ohio.

I still have a few very prolific hybrid queens that I will sell for 50c each. Queens ready to go by first mail. Safe arrival guaranteed.

GEORGE P. KIME, Evansburgh, Coshocton Co., Ohio.

I have 15 or 20 hybrids which I will mail at 50 cents each. Pound of bees, frame of brood, and honey in nucleus hive, \$1.50 more. Two-year-old Italian queens, 75 cts. Bees as above, \$2.00.

CHAS. R. BINGHAM, Edinburg, Portage Co., Ohio.

Speak quick if you want them. Several dark or small Italians, several fine hybrids, and several dark hybrids, at 15, 20, and 30c each, according to merits. No poor ones sold. Sent in Pect cages.

C. WECKESSER, Marshallville, Wayne Co., Ohio.

Bee-Keepers, Attention!

NOW IS THE TIME TO ITALIANIZE CHEAP.

I will sell, during the next 30 days, fine queens, bred from my best strains of Italians and Albinos, at the following very low prices:

1 queen	\$1.00	12 queens.....	\$9.00
6 "	5.00	50 "	35.00
Tested..... \$1.50			

Order now, or you may be too late to secure these low prices. Address **Wm. W. CARY,**

Coleraine, Mass.

Italian Bees For Sale at \$5 Each.

Ten frames, combs all built on wired foundation, and filled with honey and brood. Hives all well painted. Queens raised from imported stock. Will ship during August and September.
16-17d **A. F. PROPER, Portland, Jay Co., Ind.**

W. J. ELLISON, STATEBURG, SUMTER CO., S. C.,

Has a lot of fine Italian queens raised from splendid stock, that he will sell at \$1.00 each; \$9.00 per dozen, or \$85.00 per hundred. Safe arrival guaranteed.
16-17d

DADANT'S FOUNDATION FACTORY, Wholesale and retail. See advertisement in another column, 3b1fd

Names of responsible parties will be inserted in any of the following departments, at a uniform price of 20 cents each insertion, or \$2.00 per year.

\$1.00 Queens.

Names inserted in this department the first time without charge. After, 20c each insertion, or \$2.00 per year.

Those whose names appear below agree to furnish Italian queens for \$1.00 each, under the following conditions: No guarantee is to be assumed of purity, or anything of the kind, only that the queen be reared from a choice, pure mother, and had commenced to lay when they were shipped. They also agree to return the money at any time when customers become impatient of such delay as may be unavoidable.

Bear in mind, that he who sends the best queens, put up most neatly and most securely, will probably receive the most orders. Special rates for warranted and tested queens, furnished on application to any of the parties. Names with *, use an imported queen-mother. If the queen arrives dead, notify us and we will send you another. Probably none will be sent for \$1.00 before July 1st, or after Nov. If wanted sooner, or later, see rates in price list.

FOR SALE. ONE TO FIFTY COLONIES OF BEES.
17-18d **W. S. WARD, Fuller's Station, Albany Co., N. Y.**

HONEY COLUMN.

CITY MARKETS.

MILWAUKEE.—*Honey.*—New crop coming in slowly. Demand is greater than supply. Prospects are, prices will rule considerably higher than last year, on account of light crop. New comb, 1 and 2 lb. sections, quotable at 14½c. Extracted, 5 and 10 gal. kegs, 70c. A. V. BISHOP, Aug. 20, 112 W. Water St., Milwaukee, Wis.

CLEVELAND.—*Honey.*—Market is not very active with us; but choice 1-lb. sections are selling moderately well at 14½c. Old honey sells no better than at last report. We are holding it at 10½c, but none selling. Extracted is not wanted at any price. B. SCHULZ, 206½ E. 23c. A. C. KENDEL, Aug. 20, 1885, 115 Ontario St., Cleveland, O.

CHICAGO.—*Honey.*—The honey market is without special change this week. The receipts are heavier, demand also better, at 15½c per lb. Extracted, without change, 5½c, according to body, flavor, etc. There is no outside demand for honey, it being almost entirely city trade at present. *Beeswar.*, 23c. R. A. BURNETT, Aug. 20, 1885, 161 So. Water St., Chicago, Ill.

CINCINNATI.—*Honey.*—The market is extremely dull for all kinds. Outside of our regular custom from manufacturers, there is hardly any demand for extracted honey, excepting in the small way. Offerings and arrivals are plentiful. Extracted honey brings 4½c on arrival. There is not much new comb honey in the market, which would bring 12½c on arrival for choice. *Beeswar.*, demand keeps pace with arrivals, and brings 20½c on arrival. CHAS. F. MUTH, S. E. Cor. Freeman and Central Avenues, Aug. 20, 1885, Cincinnati, O.

ST. LOUIS.—*Honey.*—There is no change in our honey market since our last report. We look for large receipts and fair prices next month. Extracted honey, 3½c, in bbls., "Southern." New Northern white clover, in cans, 9½c. Old comb honey not salable. Very little new in market. About 16c for white-clover 1-lb. sections. *Beeswar.*, 22½c; stock large. W. T. ANDERSON & Co., Aug. 22, 1885, 104 N. Third St., St. Louis, Mo.

BOSTON.—*Honey.*—We have no change to speak of; we have had some new Vermont white clover in 1-lb. sections, and it is very fine, and there is a large crop. Prices remain 16½c for 1-lb. sections; 14½c for 2 lbs. Little or no sale for extracted. BLAKE & RIPLEY, Aug. 21, 1885, 57 Chatham St., Boston, Mass.

DETROIT.—*Honey.*—There is but little doing yet in the honey market. Quotations are 10½c for 1-lb. sections. A. B. WEED, 407 Woodward Ave., Detroit, Mich. Aug. 22, 1885.

WANTED.—Prices on clover and basswood honey, extracted. Lowest cash price. C. L. HILL, Dennison, Ohio.

FOR SALE.—15 kegs of choice white-clover and basswood honey at 8c. Kegs hold about 180 lbs. L. C. WOODMAN, Grand Rapids, Mich.

FOR SALE.—4000 lbs. very fine quality white extracted honey, in 5, 10, and 17 gallon kegs, at 9c per lb., including kegs where an equal number of the 3 sizes are taken. Single kegs, 5 gal., 10c; 10 gal., 9c; and 17 gal., 8c per lb. here, kegs included. Also 2000 lbs. in 4¼x4¼ sections, the finest lot for 20 years, put up in fancy cases with glass front, for retailing from. Price 15c per lb. here. O. H. TOWNSEND, Alamo, Kal. Co., Mich.

EXCHANGE DEPARTMENT.

Notices will be inserted under this head at one-half our usual rates. All ads. intended for this department must not exceed 5 lines, and you must say you want your ad. in this department, or we will not be responsible for any error.

WANTED.—To exchange Chaff and Simplicity hives, wood brood and wide frames, sections in flat, or set up, at A. I. Root's lowest prices, guaranteed as well made, and as good material, for new extracted clover or basswood honey at 9 cts. per lb. 17d J. B. McCORMICK, Fredericksburg, Wayne Co., O.

WANTED.—To exchange bees in L. hive for thoroughbred poultry. 16-17d B. J. PERCELL, Concord, Ky.

WANTED.—In exchange for new varieties of strawberries and raspberries, Plymouth R. Ks. Light Brahmas, Pekin Ducks, new varieties of potatoes, and small-fruit plants, cherry and quince trees. P. SUTTON, Exeter, Luz. Co., Pa. 16-23db

WANTED.—To exchange salt mackerel in 20-lb. pails, for good extracted honey. 17-18d E. E. LING, 11 Silver St., Portland, Maine.

WANTED.—To exchange one No. 2 Zimmermann Evaporator, one Violoncello, one Louis Fountain pump, one 150-egg Incubator, warranted; 100 thoroughbred P. Rock and other fancy poultry, for choice comb or extracted honey, or offers. Circulars free. J. T. FLETCHER, 17 West Monterey, Clarion Co., Pa.

WANTED.—To exchange \$10 press, 3 fonts type, can of ink, 2 type-cases, for 3 or 4 two-frame nuclei with queens. E. F. WILCOX, La Grange, O.

WANTED.—Extracted or comb honey or both, in exchange for a one-horse-power "Shipman" engine, in good order. It has been used but a short time. The fuel used is coal oil. It is suitable for hive-making, running sewing-machines, or a small boat. Address B. SALISBURY & Co., 17d Battle Creek, Mich.

WANTED.—To exchange a full colony of Holy-Land bees in Mitchell frames, 10x12, for one dozen Brown Leghorn chickens—Jewett combs preferred. DAVID LUCAS, Jewett, Ohio.

WANTED.—To exchange hybrid and black queens for dollar or tested Italian queens, or chaff-hive bodies in flat or made up. 17d J. A. BUCKLEW, Clarks, Coshocton Co., O.

WANTED.—Comb or extracted honey, or offers, in exchange for bee-hives, section boxes, bee-hive machinery, foot-power saw-mandrels, or a first-class Incubator; been run two seasons. 17d D. S. HALL, So. Cabot, Vt.

WANTED.—To exchange Cuthbert and Turner raspberry-plants, for good varieties of strawberry-plants, or queens, or offers. 17d W. C. GILLETTE, Le Roy, Genesee Co., N. Y.

TIN POINTS

For Glassing Honey Sections, Machine Cut. Standard size on hand, or any desired shape cut to order from bright tin, and at lowest prices. 17-18d

C. R. ISHAM, Peoria, Wyo. Co., N. Y.

❖ FOR SALE. ❖

50 Colonies of Italian Bees on wired Langstroth frames, in shipping-boxes, \$5.00; or shipped in my double-walled wintering hive, \$7.00 per colony, with stores enough to winter them. Safe arrival-guaranteed. GEO. E. HILTON, 17d Fremont, Newaygo Co., Mich.

HEADQUARTERS FOR TIN POINTS.

Price, 20 cts. per 1000 by express; by mail, 30 cts. W. C. GILLETTE, Le Roy, Genesee Co., N. Y.

NOTES FROM THE BANNER APIARY.

NO. 69.

QUEEN-EXCLUDING HONEY-BOARD.

YES, our only objection to the wooden queen-excluding honey-boards is, that the bees fill the openings. It is possible that this will yet be remedied; if it isn't, we shall be obliged to use the perforated metal. The bees filled the openings very much more this year than last; but why, we can not say.

INTRODUCING VIRGIN QUEENS.

We do not understand why Mr. Doolittle has so much trouble introducing virgin queens. Like yourself, Mr. Editor, we introduce them in large numbers, often as many as twenty per day, and the loss is so slight as to be scarcely worth mentioning. The bees are more apt to accept a virgin queen when they have been queenless 24 hours; but even when introduced the same day that the laying queens are removed, we do not lose more than one in ten. We didn't let them run in at the entrance, as we have met with more losses by that method. The bees are more inclined to attack a queen when they find her where they don't expect to find a queen. A young queen is always found upon the brood-combs, usually upon the brood; hence there is the place to put her. We remove a comb that contains brood, lean it against the hive, place the queen among the bees upon the brood, and then watch the bees. If one or two minutes elapse, and the bees pay no attention to the queen, except it be to caress her or offer her food, we replace the comb. If the bees attack her we smoke them. If they attack her again, we smoke them again. This watch-

ing and smoking is kept up until the bees let her alone, even if it takes ten minutes. Perhaps half a dozen times the present season we have found a nucleus that would not accept a queen after they had been "corrected," even for ten minutes. The queen was then given to some other nucleus, and the "obstreperous" nucleus given a queen-cell. Usually the queens are accepted with no trouble; and when the bees do object, one or two smokings usually induce them to change their opinions. We prefer to introduce virgin queens to giving queen-cells, for the reason that we can see the queen and know that she is perfect.

We have this year been trying the

JONES METHOD OF GETTING QUEEN-CELLS.

And one who has never tried it will be much surprised if this method is given a trial, at the large number of fine queens that will be secured; finer, in our opinion, than those reared under the swarming impulse. Before swarming began, our queen-cells were built in full strong colonies (not by the Jones method, however), and the queens were fine and large. When swarming began, many cells used were built under the swarming impulse, and we remarked several times how inferior were some of the queens compared to those we had reared before swarming began.

Since the swarming season we have been using the Jones method, and are delighted with it. We see to it that some colony has larvae of the right age, with holes cut in the comb to facilitate cell-building; then we shake all the bees from one-half the combs of two or three colonies, in front of the hive where the cells are to be built. We thus get a great mass of bees; the hive is jammed so full that some of them are crowded out of the entrance

most of the time. You may think, friends, that this is an expensive way of getting cells; but, try it once; and when you come to cutting out the cells you will think it is cheap. The queens hatch about a day sooner, and commence laying sooner, besides being large, strong, well-developed queens. The cells that are built under the swarming impulse, in a full colony, before the swarm issues, are fine cells usually; but those that are built after the swarm issues are rather inferior. If nature is allowed her way, of course the inmates of these later-built cells seldom become the mothers of colonies.

THE CANADIAN BEE JOURNAL.

This is proving to be a real, live, practical bee-paper. We have learned quite a number of little "kinks" from it that have been worth more than the cost of the journal. One is, that of

HIVING SWARMS IN A TENT.

When two swarms issue at once, set a wire-cloth or mosquito-netting tent over one of the hives, and let the swarm cluster in the top of the tent. Why wouldn't it be a good plan, in a large apiary, to have three, four, or more, of these tents "standin' round kind o' handy like," all ready to set over hives when the swarms come "thicker and faster"?

THE HEDDON METHOD OF PREVENTING AFTER-SWARMS

Has been a decided success with us for three years; and how it should fail with Mr. Doolittle and his neighbors, or any one, is a puzzle to us.

HIVING SWARMS ON FDN.: DOES IT PAY?

We have been experimenting again this year with empty frames vs. fdn., and the indications are, that fdn. in the brood-nest is a damage, when the swarms hived upon it are given access to a surplus apartment furnished with fdn. Twenty swarms were hived upon fdn., and about 25 others were hived upon empty frames; i. e., empty except "starters" of fdn. one-half inch wide. The swarms were hived alternately as near as it was possible to have them, considering that five more were hived upon empty frames than upon fdn. The swarms hived upon empty frames stored, in the sections, 16 per cent more honey. Their brood-nests were 7 per cent lighter than those given fdn. In the aggregate — i. e., counting both the honey in the sections and in the brood-nest, those furnished with fdn. fell 5 per cent behind. Prof. Cook says bees do not secrete wax unless they need it; but does it necessarily follow that they can not secrete it except at a loss in the amount of honey stored? Our experience says no. 8—W. Z. HUTCHINSON, 70—100.

Rogersville, Genesee Co., Mich., Aug. 21, 1885.

Thanks for the valuable facts from experience you give us, friend H. So you are now master of a hundred colonies! Now, then, will you permit an old friend to suggest that you take immediate steps toward making the hundred colonies keep in good shape until next May? In our own apiary, that is just the point we are beginning to face once more. We have done it pretty well for a year or two; but the question is, Can we keep it up? — It seems to me as though it were destined to be an established fact, that new swarms that have an opportunity of working in sections well supplied with fdn. are better off without fdn. in the brood-frames. Our sales of fdn. have been very much less during the past year than for years past—especially fdn. for brood-combs. But another

thing comes in here: How many of those brood-combs contain more or less drone-comb? I should want all of my brood-combs built on fdn. supported by wires, even if they cost something extra. I do think we ought to be getting our fdn. thinner and lighter, both for brood-combs as well as surplus honey; and we are now able to make a very fair article at 12 square feet to the pound. But this, in my opinion, is still too heavy where full sheets are used in the section boxes. Whenever we have comb honey on the table I am reminded of it, for the fdn. is almost too prominent an object when we are cutting up the honey to spread it on bread and butter. We have had samples of the thinnest made by our different makers, but I believe there is none sent out, as a general thing, running more than 12 square feet to the pound.

CRYSTALLIZED HONEY FROM HONEY-DEW.

HOW IT COMES, AND WHAT PRODUCES IT.

I HAVE to-day sent you by mail three packages containing samples of the so-called crystallized honey-dew of Oregon. No. 1 contains stalks of fireweed (*Epilobium angustifolium*), with the insect that caused or produced the crystals. The insects have been on these stalks since the 20th of June; and when they first appeared they produced clear drops of sweet water; and as it evaporated it produced the crystals as you see them. They are only in small patches, and there is about one stalk in a hundred like the samples, and the country where I got the samples is covered with the fireweed. The bees do not work on the honey-dew, but prefer to get the honey out of the flowers of the fireweed. I think they are wise that they do, for the honey that they get is as white as snow; and when it is extracted it looks as clear as snow.

No. 2 contains cuttings from two white-fir bushes that grow in the street of a small town, and there are about thirty colonies of bees within one-fourth mile of them, and they hum about them all day, but I don't think they would notice them if they had plenty of flowers to work on.

I do not know how long these insects have been on these trees. The first time I saw them was about three weeks ago, but I have noticed the same insects on the red and yellow fir since the 25th of June, but not so plentifully as on the samples; and I think the reason that the samples look so black is because of the dust from the street settling on it, for it looks as clear as water when first produced. The insects all sit close together, with their heads sticking close to the bark of the branches. They don't seem to move, and the juice oozes out on their back in small drops, and falls on the branches below, or on the grass. I saw some drops on some of the bugs as large as a small pinhead.

Now, Mr. Root, I think this is where the crystallized honey-dew came from that Mr. E. S. Brooks sent you in 1883 (see GLEANINGS for 1883, pages 541 and 670).

No. 3 contains cuttings from a willow brush with the insect that produced the honey-dew. These insects are very numerous in the locality where I got them, and the bees hum about the trees and bushes, where the insects are from morning till night, but

there are no flowers for them to work on in this locality, and they store lots of honey from this source, and the honey looks about the color of apple-blossom honey, but doesn't suit nearly as well.

These insects made their appearance about the 20th of June, and they work on several different plants and trees, but seem to prefer the willow.

I have heard a great deal of talk about this honey-dew, but I never had an opportunity to examine it to till this summer, and I have not found any honey-dew yet where there were no insects to produce it; and I don't believe I ever shall; but the people in this country all think it falls the same as natural dew.

Bees have done well so far this season, and are still getting honey from thistle and honey-dew (or bug-juice). D. KAUFFMAN.

Needy, Ore., August 3, 1885.

Many thanks, friend K., for your valuable samples. We will at once forward the insects to Prof. Cook, and may be he can tell us something more about this insect that produces not only the honey-dew, but solid candy that would do credit to a confectioner.

OBSERVATIONS AND CONCLUSIONS ON QUEENS.

Does the Number of Days in the Cell bear any Relation to the Longevity of the Queen?

HATCHING.

I HAVE had queens hatched on the 8th, 10th, 11th, 12th, 14th, 15th, and 16th days from starting of cell. Those early-hatched queens were raised from larvae several days old; the one on the 8th, I judged to be about five or six days old when cell was started over it. It was raised by a prime swarm of black bees which lost their queen at hiving. A swarm that issued Monday, 2 P. M., hived on empty comb and foundation; Tuesday morning, 8:30 A. M., restless; found a dead queen in front of hive, and at once gave them a comb of Italian brood. On Wednesday morning I found a cell well advanced, and on the next Wednesday, 10 A. M., the queen had hatched and destroyed the remaining cells. The following is the approximate duration of life and prolificness of queens compared with the number of days in the cell:

1 queen hatched 8th day;	1 queen lived 9 mths; 1 fairly prolific.
1 " " 10th " "	1 " " 8 " " 1 " "
2 " " 11th " "	2 " " 1 year; 2 " "
3 " " 12th " "	1 " " 1 " " 2 " "
14 " " 14th " "	1 " " 1 mth; 1 " "
" " " 1 " "	1 " " 1 " " 1 " "
" " " 4 " "	1 year; 4 " "
" " " 5 " "	3 " " 3 " "
" " " 6 " "	3 " " 2 extra prolific.
14 queens " 15th " "	1 " " 3 fairly "
" " " 1 " "	2 " " 1 " "
" " " 4 " "	3 " " 1 ex. pro.
20 queens " 16th " "	1 mth; 1 fairly prolific
" " " 1 " "	2 " " 1 " "
" " " 2 " "	6 " " 2 " "
" " " 3 " "	1 year; 2 " "
" " " 5 " "	2 " " 5 " "
" " " 7 " "	3 " " 6 " "
" " " 1 " "	4 " " 1 ex. pro.
" " " 1 " "	5 " " 1 prolific

leaving plenty of brood and eggs at death. One queen hatched 17th day, lived 8 months, not very prolific, but fine honey-gatherer.

SUPERSEDING.

Queens are almost uniformly superseded in the spring, or within 65 days after swarming. In ten years' observation, I have only twice known the superseder of queens raised in the fall. One was the last of September, and the other died in the winter;

the other in October, the mother living until the next spring. This young queen proved to be barren, the only one I ever met with. I kept her for observation, until the 10th of July, but she never laid an egg.

Ten supersedures took place in the spring; five did not swarm that season—one at early swarming time, and four swarmed in the fall.

Four supersedures took place in from 45 to 65 days after swarming. One queen-cell was almost the uniform rule in superseding; only once have I seen this varied from, and that was in the case of early swarming above referred to. The queen was a yearling, whose wings had been badly mutilated in introducing the previous season. This swarm raised three cells, the mother dying about 48 hours before the swarm issued, and leaving the combs full of brood and eggs. The young queen began to lay eight days after swarming.

CONCLUSIONS.

Queens raised in weak nuclei, or in swarms with more combs than they can cover, are shorter lived than those raised in strong nuclei or full swarms. Queens should never be raised in less than three-frame nuclei, and they should be full of bees, and the cell on center combs.

I should prefer four-frame nuclei, full of bees, and the cells in the center space. Superseding cells are mostly near the middle, and a little above the center of the brood-nest. I believe that superseding queens, and those raised under the swarming impulse, are longer lived than forced queens. I have never met with an inferior superseding queen, except the barren one above referred to. Forced queens are those raised to replace queens purposely or accidentally removed. There is very little if any difference in queens raised in crowded nuclei and those raised in strong colonies. I crowd the combs with bees to raise queens. I always prefer a mother one or more years old, to raise queens from. Long-lived queens are, I think, always preferable. Queens may be superseded at swarming time, unknown to the apiarist, but not often, if he be a close observer. Further observation may modify these conclusions. I raise no queens for sale.

E. S. ARWINE, M. D.

Patterson, Texas, July 31, 1885.

Friend A., your observations are extremely interesting and valuable; but I can not see why you make the remark, under the head of superseding, "within 65 days after swarming." Had you said two or three months, we might have hunted up the reason for it. I have observed that more queens are superseded in the spring than at any other date. But where there is a great number of queens superseded in one apiary, I have generally found it accompanied by a sort of demoralized condition of the whole apiary; i. e., at the time when spring dwindling and troubles of that kind are prevalent. I believe it is also true, that where a young queen is reared to assist or take the place of the reigning queen, bees start only one cell; for we often find a young queen in the hive at the same time the old one seems to be doing pretty fairly; and when we find the cell she hatched out of it is usually if not always just a single cell. I have heard of queens living between three and four years; but the case you mention, of a queen that lived and did service up to five years of age, is, I

should think, a very rare occurrence. Are you sure you were not deceived, and that some of the young queens did not take her place part of the time? My experience has been as you state, that these young queens, reared while an old queen is present, are always good ones. Doolittle mentioned the same thing a spell ago, you may remember. In the table you give, we notice that you have no queens that lived to be two years old, except those that were hatched after the twelfth day; and seven that lived to be three years old were all hatched after the sixteenth day. In counting these days, I suppose you mean it was sixteen days after the bees started the queen-cell. In this case it would be pretty certain that they took the egg to commence with. Many of us have long felt that it would be more desirable to have the bees commence with the egg, but we have not had any facts before such as you give.

REPORTS ENCOURAGING.

THE PROCEEDS OF TWO SWARMS OF BEES IN THE HANDS OF AN A B C SCHOLAR.

I BOUGHT two stands of bees last May in Simplicity hives. I looked at them on the 16th, and find 110 lbs. already sealed over—\$20.00 worth here. The bees cost \$17.50. Now, it would be unumerful on my part if I would not do my utmost to winter them properly. I am a novice at the "biz." I sat for hours this summer, and handled the brood-combs, but could not find the queen or queen-cells. I gave them plenty of room and honey-boxes early, so as to size up my two swarms, and they have plenty of bees in them, but they did not swarm at all. At this writing they have made 130 lbs. surplus in boxes over them. There are bees almost by the peck. I put two stories on the strongest hive, as they would hang out for want of room. I thought by "sizing up" the swarms I could winter them better.

I find the A B C book profitable and entertaining, and that so far I have, in my short acquaintance with those in the bee business, found more good, honest, and gentlemanly business men, as a class, than with any other class I have dealt with. I don't believe there are many bad men in legitimate bee business. There is something humanizing and Christianizing in handling the little fellows. Mine have taught me many lessons this summer—lessons in morals, in business, and social life.

Harlan, Iowa, Aug. 24, 1885. W. M. BOMBERGER.

A GOOD BASSWOOD "BOOM;" SOUR HONEY AGAIN, AND HOW IT AFFECTED THE BEES.

We had that basswood boom down here too, for ten days. It was "immense," I tell you. Every little sapling seemed to be loaded down with bloom and bees.

I had a little experience with sour honey in the combs. I placed a frame containing some in the center of a strong colony, and I found the next evening the ground in front of the entrance was literally covered with dead bees. They looked as if robbing had been going on. I was unable to account for it until I saw the report from a correspondent in

GLEANINGS last month. It then "dawned" upon me that the soured honey did it. D. S. SULLIVAN, Ridgeway, N. Y., Aug. 6, 1885.

MORE ABOUT BEE-POISONING.

ALSO SOME QUERIES IN REGARD TO BUILDING UP NUCLEI.

I READ the article written by Mr. Langstroth on bee-poisoning in GLEANINGS of Aug. 15, with a great deal of interest, and also your advice to Mr. Heddon. I can imagine that I see him smile as he reads it, and says to himself, "Not any of that kind of inoculation for me if you please." Now, I object to that style of wholesale inoculation for several reasons—principally on account of the after effect which it has upon the system. If one chooses, for any reason, to go out of the business, it seems an unpleasant thought that, when he happens to meet a farmer apiarian friend and associate, on greeting him with a cordial shake of the hand one must be thrown into a paroxysm of hydrophobia, or, more properly speaking, bee-phobia. He can't be expected to carry a supply of bees around in his coat pocket to inoculate himself as circumstances may require, and he must therefore receive the shock with as good a grace as possible. It seems to me that a poison that produces such results is better out of the system than in it, and I think that it would be better to exercise a little extra caution in the handling of bees, to avoid being stung, even to wearing a veil, when bees are unusually cross.

Your article on building up nuclei in the fall was an interesting one to me, as I am engaged from small beginnings in building up as rapidly as possible, with a view to more extensive operations in the future, and I should like to ask you one or two questions on this subject.

FEEDING NUCLEI SO AS TO BUILD THEM UP TO FULL COLONIES; HOW MUCH SUGAR WILL IT TAKE?

1. How much sugar is best to feed a three-frame nucleus, beginning, say, the middle of August? Would it be well to give them all they will carry down, or is there danger of giving them too much?

2. Would it be safe, at this season of the year, to feed brown sugar, or will some of that which is fed be retained in the combs for winter use, and cause dysentery? It is the opinion of some that brown sugar is preferable; for breeding, to granulated, and it certainly is cheaper. S. A. MERION.

Brooklyn, N. Y., Aug. 22, 1885.

If you are in a locality where little or no fall honey is to be expected (and you must, of course, do the work by feeding), you will probably need 30 or 40 lbs. of sugar to make them a good colony. I would use granulated sugar, so that there will be nothing in the combs but stores suitable for winter consumption. Thirty or forty pounds of sugar will be worth at this date from 7½ to 8 cts. per lb., according to the locality; so you see that, if you have no honey yield, you can, as a rule, make colonies cheaper by sugar feeding than by purchasing them at the usual rates. You will also have the best strain of bees, and perfect combs of the most modern construction. Brown sugar would answer just as well as any thing for building up in the fall, and friend Viallon tells us they will build more comb when fed on brown sugar

than on white; but I hardly think I would risk it, for the reason you mention, that they will be greatly liable to leave some of it remaining in the comb, to be consumed during the winter.

ANOTHER FALSE STATEMENT IN REGARD TO THE HONEY BUSINESS.

A MORE DESPICABLE PIECE OF FALSEHOOD THAN WE HAVE HAD YET.

SEEING in GLEANINGS your column of "False Statements," we inclose you a "sort-o'-rough" one, clipped from the Cincinnati *Enquirer*. Reporters are a little "gassy," it seems, this year; but it looks as if they might open the "safety-valve" in another direction that will not hurt the business of our country so much.

G. W. & S. H. FOLMER.

Independence, Ky., Aug. 24, 1885.

Friend F., we are very much obliged to you for forwarding the slip of paper directly to us; and we agree with you, that it would be desirable to get reporters to turn their wonderful talents for falsifying, in some other direction. We can keep bee-men posted, even if we can do nothing more. Below we give the sensational item which our friend refers to:

HONEY; THE PRESENT SEASON A BAD ONE FOR BEES—A BIG LOCAL CONCERN THAT FEEDS THEIRS ON GLUCOSE.

Meeting a well-known enthusiast on honey-bees, who has a very extensive apiary, Wednesday, an *Enquirer* representative asked how the business of all busybodies were doing this year.

"This has," he replied, "been the worst season I ever knew for them. I don't know exactly why, except that the blossoms and the flowers which they depend on were much shorter lived than usual. The locust-blossoms, from which they extract a great deal of honey, remained on the trees but a short time; and the white clover, from which they gather the most of their stores, has been very scarce. The recent drought hurt them a great deal, and in examining my hives Sunday I found that the inmates would not lay by enough even to keep themselves the coming winter."

"Then that means a scarcity in the honey market?"

"Of the true, natural article! yes."

"Why, is there any thing else?"

"There are adulterations, certainly; but what I more especially refer to is the article sold which bees make from glucose. The honest bee-men for years have been fighting this class of dealers, and I think we are getting them gradually in our clutches."

"They do not exactly adulterate the honey, but they feed their bees on poor glucose, and the article that they make must naturally be very inferior. These men have quite extensive places where they keep bees, and the insects feast themselves on the glucose syrup. They do not like it; but finding nothing else to work in they gradually take to it."

"Is there any such establishment in Cincinnati?"

"Yes. A well-known baker on Central avenue has all the upper floors of his establishment devoted to this style of honey manufacture. The article made is very tame and very tasteless."

You will notice that the above has a shadow of truth about it in the fore part of the communication, and I presume it strikes almost every one of our readers, before he gets through, that the reporter had in mind our good friend C. F. Muth. It seems to me most astonishing, too, when we remember that Mr. Muth is perhaps more fierce against glucose, grape sugar, and the like, than any other bee-keeper in our midst. Perhaps half of the people in Cincinnati know that

he has an apiary on top of his house, and he has a brother in the baking business; but the two are well known to be such good straight staunch men, that it seems strange the reporter should not have known better, ere he published any thing of the sort. Mr. Muth handles more honey than perhaps any other one man in the United States, unless it be some of the friends in California; but the statement that the honey he sells is tasteless, almost every man, woman, and child anywhere about Cincinnati knows to be a falsehood. If it were possible to get this reporter, and take him to friend Muth's establishment, and make him aware of the awful falsehood he has started, it would be the right thing to do. From what I know of friend Muth, I presume he will not do any thing about it; but I wish that somebody who knows something about honey would write to the *Enquirer*, and ask the editor to correct such a slander on one of Cincinnati's best business men. I might mention, also, that this newspaper canard mentions the very street on which friend Muth lives. Mr. M. never feeds his bees any thing—much less, glucose; but during favorable seasons he produces some of the finest crops of honey made by any one in the State, even if his bees are on a house-top, virtually, while the rest of us have them on the ground.

A KIND WORD FOR FRANK BENTON, FROM FRIEND VIALON.

ALSO SOMETHING FROM YOUR HUMBLE SERVANT IN THE SAME LINE.

FRIEND ROOT:—There were a few remarks made in regard to the supposed neglect of Frank Benton in not mailing queens promptly, etc. I am positive that the delay was unavoidable; as I must say, in justice to him, that I rarely dealt with any one more prompt; as, for instance, I wrote to him on the 9th or 10th of June last, and on the 13th of August I received an Italian queen, though I had not sent him the money, and had only expressed the wish, etc. I think great credit is due to him for mailing queens with such good success across the ocean. The queen he sent me was 16 days in reaching us; and though she came sealed up in a registered-package envelope, she was alive and in good condition, and not one of her escort was dead. What kind of candy he uses is hard for me to say, as there was so little left; but nevertheless he succeeds as well as we do, though our queens are only three to five days in the mails. I think friend Benton should be as generous as friend Good, and give the formula of his candy, and thus receive the thanks of all.

Bayou Goula, La., Aug. 17, 1885. P. L. VIALON.

I agree with you, friend V., and I beg pardon for what I said in regard to the delay on our Camiolans. There is one other thing I want to say, for the benefit of friend Benton. In his anxiety to show us that he has succeeded so well in mailing queens across the ocean, he has, to my knowledge, sent a great many queens to other parties as he did you, friend V., before he received the pay. Now, most of the friends who received them, like yourself, felt it a privilege to show him how

promptly they could remit, under such circumstances: but there are some (one or two, any way) who have not paid him even yet. Now even if the queen should be received dead, friend Benton should surely have the privilege of replacing her, or the party who received her should stand at least part of the loss. No man ought to be asked to send queens, and not receive a copper by way of remuneration, even though he should fail once or twice in getting them through alive. You may remember that I have written on this before. In regard to friend Benton's candy, he promised some time ago a full description of how he prepared the candy, and how he prepared the cages. And I think I offered him \$25.00 for such an article; if I did not, I hereby make the offer. Friend Benton is laboring under great disadvantages, and he is laboring, too, for the good of the world. From what I have learned, I am afraid he is not getting very warm support from the brethren at home. Can we not encourage him a little in his undertakings, and give him a lift in the way of some good orders? And if every thing should not turn out to our liking, can we not be a little generous under the circumstances, and show him that we have not forgotten a brother bee-keeper who is working for us, away off in the Old World?

THE OHIO STATE BEE-KEEPERS' ASSOCIATION AT THE STATE FAIR.

TO THE BEE-KEEPERS OF OUR STATE.

AT the present writing I have received no information in regard to where the convention will be held, nor on what special days of the fair. The opening day of the fair is Monday, August 31. Now, then, if it is the wish of the people that I, as president of the association, shall decide upon the time of meeting, I would suggest Thursday and Friday, Sept. 3 and 4. My experience has been, with conventions held during fair time, that the attendance has usually been meager, and the interest rather vacillating, compared with conventions held at other periods. The reason of this, doubtless, is owing to the fact that there is so much going on at fair time, and also because many of our bee-keepers are interested in fine stock and agricultural products in general, which is all very well and proper. But for all that, we ought to be willing to lay aside other things during the hours of the convention, and make it a convention in real earnest. In order to do this, would it not be well to have the length of each session comparatively short? I would suggest that we open the exercises at nine o'clock, Thursday morning, to continue two hours, and devote the time between 11 and 12 to shaking hands, and getting acquainted—a sort of "social," if you choose. This will permit those who have other business on hand to get away at 11 o'clock, if they wish, and yet without interfering with the interest of the meeting by going out and in. Then let us meet in the afternoon, say at 2 o'clock, and continue till 4 o'clock.

My experience has been, that the most in-

teresting meetings during fair time are in the evening, because there is less outside interest to attract attention after dark. Let the evening meeting commence at 7 o'clock, and continue till somebody moves to adjourn, providing it be not kept after 10 o'clock.

The second day, Friday, I would have about the same hours as the day before, omitting the meeting in the evening, if thought best.

In regard to the manner in which the time shall be occupied, I would follow the example of some of our most successful conventions in the State of Michigan, by omitting long essays. Bring as many questions as you like, and also bring all the facts—especially facts not heretofore mentioned, as far as may be. Of course, if arrangements have been made for essays, we shall be most glad to hear them, providing they are not too lengthy, in view of the brief time I have allotted. Of course, if any other arrangements have been made, I will with great pleasure set the above arrangement aside; but I believe it is generally agreed that it is a hard matter to have a successful bee-keepers' convention during fair time. All present seem to feel as if they were off for a playspell or a recess, and they are impatient, somewhat, at any kind of restraint. After what our good friend Mrs. Jennie Culp has said, of course I would extend an earnest invitation to have the ladies present; and I should like to have the juveniles come out, especially all who are interested or working with bees. I shall be most glad of the opportunity of taking them by the hand, and getting acquainted with the juvenile bee-keepers of the State of Ohio; and to make you feel a little more at home, Blue Eyes (whom I presume most of you have heard of) will go with me. May be if we get juveniles enough to come out, we can have an extra session specially for them; and reports or essays from them would always be in order. I shall be very glad indeed to have them bring specimens of their work, in the shape of honey, implements for the apiary, or queen-bees that they have raised, as well as drones and workers. Wouldn't it be a grand thing if Ohio could take the lead in inaugurating a juvenile State bee-keepers' association?

In regard to the place of meeting, I suggest that we have a good-sized and commodious hall, if such a one can be found, on the fair-ground. Much depends upon the place where we meet, and the surroundings. Let us not be backward about a little expense, if that will help the matter. If some of the friends will secure such a hall, if it be not already secured, and have it announced by large plain placards, to be put up in several conspicuous places, at the place of exhibit for honey and bee-supplies at the State fair, I shall be greatly obliged. May be this has been done already; but for fear it has not been attended to, I make these suggestions. Without question, a large body of bee-keepers will be in attendance at the State fair; and the desirable thing is, to get them together and get them acquainted with each other.

SOME EXCELLENT DEVICES OF D. A. MCCORD'S.

BY L. L. LANGSTROTH.

WHEN extracting I always rested the frame upon the portico roof of my hive, brushing off the bees from one side of the comb, and, without lifting, swinging the frame around so as to brush them off from the other side.

My friend Mr. D. A. McCord has devised what he calls McCord's comb-rest, which may be applied to any style of hive. Any one who has practiced holding the dead weight of heavy combs, while brushing off the bees, will appreciate this labor-saving device. With the cut, the inventor gives the following description:

MCCORD'S COMB-REST.

This is the simplest and cheapest device to rest the combs upon while brushing off the bees. It consists of one piece of board about $\frac{3}{4} \times 6 \times 15$ inches; one piece $\frac{3}{4} \times 4 \times \frac{1}{2}$, nailed one or two inches below the top of the 6-inch piece, and two logs $\frac{3}{4} \times 2 \times$ about 21 inches long, nailed as shown in the cut, and it can be made in fifteen minutes. Lean the rest against the front of hive. Set the bottom corner of the frame on the pointed nail, holding the opposite top corner in the left hand; brush the bees off with the manilla brush held in the right hand. It can be used with the upper story on or off.

MCCORD'S MANILLA BRUSH.

This brush should be fastened into the handle with shellac instead of glue; and while using it, it should have the ends dipped in water often enough to keep them soft.* I have used a brush of this kind for two seasons, and brush off the bees without any protection, and sometimes will not be stung in a whole day.†

Mr. McCord also tells how to use the Root chaff hive with reversible frames, so that the bottom frames may be taken out without removing all the top ones.

Take off the upper tin rests and nail a strip to fill the crack. Tack the tin rests on the same sides as the bottom ones, with strips $\frac{1}{2} \times \frac{1}{2}$ nailed under them to support them firmly. The top frames will now hang from front to rear, same as bottom ones. Now shove the reversible wires about half way off at

* Always have a pail of water handy when taking out the combs for extracting—not merely to wet the brush, but to fill an end comb when returned, and save in the height of the honey season, the labor of mussy bees.—L. L. L.

† I can strongly indorse the McCord brush. With its long handle and the manilla put on both sides, and in the right position, it works admirably. When Mr. McCord used a small wisk broom he always wore a bee-hat, and the bees were often enraged. No doubt many were hurt.—L. L. L.

each end, and the frames will hang in the upper story; and in a moment the wires can be pressed in when they are to be put in the lower story.‡

When common frames are used, make the top part single 8 and fasten in rests $\frac{1}{4}$ inch by 2, made of hard wood, with a sharp upper edge for the frames to rest on. The spaces on the sides will not be filled by the bees when idn. and extracting are properly attended to. I have tried hives with this space for a number of years, to my satisfaction. Oxford, O.

D. A. McCord.

In closing this article I will simply say, that the plan given by me four years ago—the same now described by Mr. McCord—may very easily be applied to any of the thousands of Root's chaff hives now in use. To be under the necessity of taking out all of the upper frames when perhaps you want to examine only a single one below, as, for instance, a central one, to see if a young queen has begun to lay, is, in my opinion, an insuperable objection to the present style of this hive, and should never be tolerated by one who can avail himself of the better way.

Friend Root, if I could only get you to alter a single hive in your apiary, you would see the point. I have always tried to make all the improvements in my hives such that, if possible, they could be applied to all hives already in use.

Two years ago I saw at the apiary of our friend Hill, at Mount Healthy, O., what he considered the best plan for wiring frames—only two wires very tight. He said they answered all the purposes of

wires. If so (and he is not the man to say a thing will do when it will not), how much better his plan than the way you have adopted in your reversible

frames! Too much complication is the bane of bee-keeping, and into that all supply-dealers naturally fall, unless they set their faces against it all the time. You are wisely opposed to multiplying loose fixtures, going even to the opposite extreme. Can you not, in this matter of wiring frames, keep nearer to the "simplicity" idea with which you started?

I shall be glad to hear what success attends the reversible frames. I attach little importance to them for securing combs built completely down to the bottom rail of the frame. As soon as a comb becomes a little old, the bees put an extra amount of wax at its lower edge. Cut off about half an inch of this for the wax-extractor, and put in a nice strip of worker comb, and you have what you want. It pays, I think, to do this with all old combs; you can do it if you wire no more than Hill does.

Oxford, O., Aug. 4, 1885. L. L. LANGSTROTH.

I have often thought of a comb-rest, similar to the one our friend McCord describes; but as it requires an additional piece of furniture, to be carried around from hive to hive, I have decided it would be more trouble than value; however, there may be others who think differently.—When using a portico hive, my favorite place has been for resting one corner of the comb on the portico, and swinging it around on the corner.—The manilla brush is quite similar to brushes that have been submitted several times. If I am not mistaken, we have before illustrat-

‡ The bees will not fill in back of the frames when idn. is given, or the extractor is seasonably used.—L. L. L.

§ This is what I recommended four years ago. To make the top story double is worse than wasting room and material, for in winter it tends to keep the cushion damp, acting like a cellar.—L. L. L.

ed a brush with fibers on both sides.—In regard to the plan of hanging combs in the top of the chaff hive parallel with those in the lower story, I confess that it never before occurred to me that the reversing wires would make this an easy matter. It strikes me, however, that the reversing wire would have to be fastened back at the proper distance by a little block, or perhaps a tack, placed at the proper point on the top-bar of the frame; the reversing wire might then be snapped under the head of this tack, or slipped clear over it. It can be worked in the way you suggest; the only question is, will it not be too much machinery? When we are using the upper story of the chaff hive for extracting, or when it is filled with frames of sections, we seldom handle the combs in the lower story very much.—Two horizontal wires, instead of the manner in which we wire frames, have been suggested several times. But diagonal wires add greatly to the strength of the frame. The perpendicular wires are so much shorter than those running from side to side, that they give greater strength for the same size of wire. We have decided that we want all of our combs made from fdn. securely supported by wire of sufficient strength, and placed at the proper points. I hardly think the arrangement you mention would be strong enough to ship frames filled with fdn., which we do quite largely, although it answers all purposes the way friend Hill handles his combs in raising honey and not selling colonies.

FRIEND FOWLS' EXPERIENCE DURING THE PAST SEASON.

A Good Report of some of the New Devices—Reversible Frames, Heddon Cases, Hutchinson Honey-Board, etc.

REVERSIBLE FRAMES.

EDITOR GLEANINGS:—I have 200 reversible frames in use, but I can give only a partial report, because I did not have reversible combs when building up in the spring. But I had them in swarming time; that is, I had reversible frames filled with foundation, and I am so well pleased with them that I would have them for new swarms, even if the cost were ten cents additional, instead of one. Nine or ten days is often enough to reverse the combs, in my opinion. When the combs are filled with brood below and honey above, I reverse them, throwing the new-laid eggs at top, and unsealed honey below. If any is sealed I mash the caps with a knife, sliding it over so as to flatten without slicing them off. This is better than to extract, to get out the sealed honey, as there need be no shaking of combs, and no interruption of the day's work. In nine or ten days more the brood will be sealed at the top. I now reverse so as to bring eggs and larvæ at the top, and capped brood below, when it will hatch, and the queen will refill the comb with eggs. In nine or ten days the combs will be brood in its different stages, when I reverse again, and so on through the season. In short, I reverse often enough so that no bees are allowed to hatch in the upper part of the frames.

CONTRACTION OF THE BROOD-NEST.

In hiving new swarms I usually contract the

brood-nest to four or five S. frames. If more are used, and they are all reversed, the outside frames will be solid with honey, and the central ones solid with brood. I haven't had very good success getting sections filled at the side of the brood. Before they were finished, the queen would be sure to get into them, and I would have to take them out, put division-boards in their place, brush off the bees, and hang them in the top story of some hive that was working in wide frames. This takes up time. Will friend Heddon tell us if he contracts the brood-nest? and if so, will he please tell just how he does it?

HEDDON CASES.

I sent to friend Heddon for a sample case and honey-board, and then had 60 cases and 30 honey-boards made to order. I made my hives myself, to fit the cases and to take the S. frame, which I use. I like the Heddon case very much, and never expect to go back to wide frames again. I find a much smaller per cent of bulged and imperfect sections in those from Heddon cases than those from wide frames, and the work of cleaning for market is much less. Right here, Mr. Editor, it is my opinion you are on the wrong track. You seem sure that the bees will propolize the tops and bottoms worse when the bees have free access to them. Why, friend Root, any one who has seen my crop of honey will bear me out in saying, that all sections from wide frames are propolized *worse*, and a large proportion of them are ten times as bad.

MOORE'S CASES.

I had 20 of the Moore cases in use; and although the sections are cleaner than those from wide frames, they do not compare with those from Heddon cases, because there is no bee-space on top; and every time the enamel is peeled up and replaced, a new line of propolis will be added, exactly as it is on brood frames when mats are used. If I had never used the Heddon case, I should very likely prefer them to any thing else; but in the light of present experience I would have the Heddon case made to fit the Simplicity hive, and have the honey-board with a sink on both sides, and it would be reversible. Do you see?

HEDDON HONEY-BOARDS.

Friend H. deserves at least a vote of thanks for bringing this before the public. I think they will pay for themselves in one season, in the saving of time and labor. I think they would be just as useful if an upper story with wide frames were used. It is very important, however, that the spaces come over the top-bars of the brood-frames. In using division-boards on each side, I got some of them on so as to make continuous passages. I soon found this would not do at all. The bees would fill the spaces, and fill the under side solid with honey. When arranged just right the spaces will be clear, with but little underneath.

HUTCHINSON'S PERFORATED HONEY-BOARDS.

I had eleven of these in use, and I think they would usually keep the queen down if the saw-cuts were as accurate as the one sent as a sample. I presume the man who cut them moved some a trifle to one side while making the perforations. Such boards, with a few holes too large, are a nuisance. The queen gets above, and, unlike the neighbors' pigs when they get into your garden, she is sometimes unable to find the hole she went in at, and, being confined above, takes possession of the sections

when she might not have laid an egg there if wide-spaced boards like Heddon's had been used.

THE SEASON.

The season so far has been very good. I have secured a good crop of fine clover and basswood honey, mostly basswood. New swarms have produced from 25 to 75 lbs. of comb honey, according to size, time of hiving, etc. CHALON FOWLS, 42—90.

Oberlin, 5 O., Aug. 11, 1885.

Thanks, friend F., for the valuable facts you give us. We are glad to hear so good a report of the reversible frames, and also for the Heddon case. I presume I have been on the wrong track, no doubt; but I don't think I am now. I should be very stubborn indeed if I were to reject the abundant evidence given us in regard to the efficiency of the Heddon honey-board in keeping propolis, etc., away from the sections. Besides, we are now selling on the streets of Medina the nicest honey we have ever handled, and it was secured by the Heddon system. The Heddon case as we make it, adapted to the Simplicity hive, I believe secures all the advantages you mention.—I am very sorry indeed if any of our honey-boards have been sent out in the way you mention. I will call particular attention to the matter, and instruct our foreman to have the perforating done by a careful man who understands the consequences of moving the boards even a hair's breadth while over the saw. We presume, of course, the honey-boards you refer to were made by us.

VIRGIN QUEENS, AGAIN.

MORE ABOUT CONFINING QUEENS IN THE CELLS.

ALTHOUGH I have nothing new to offer, giving light on how to introduce virgin queens, more than I gave on page 522, still I wish to say a few words relative to virgin queens, and where to keep them. While I know that, when left to their "own sweet will," virgin queens are constantly on the move, as friend Root speaks of on page 523, still, from the experience I have had, I consider this by no means necessary, as all the virgin queens I have succeeded in introducing at from six to nine days old have proved to be the very best of mothers, and none were allowed a cage larger than a 1½-inch hole bored in a one-inch board. I keep all my virgin queens in an Alley queen-nursery, and consider it just the thing to keep such in. Were I using a lamp nursery, I would cage all the cells so as to save the endless watching necessary when the ordinary plan is used; for an Alley cage allows of many advantages not gotten without it, besides preventing the queens from killing each other, should they feel so disposed. And this brings me to the quotation from the *Canadian Bee Journal*, found on page 532, which I had before read in that paper, which shows that a queen can be confined to the narrow limits of a queen-cell for six days after maturity, and still be just as good as are those which have a full hive to keep up an endless parade in. Friends Jones and Root seem to think this "novel," and not "easily accounted for," while from the editorial on page 539, it is inferred that the queen fed herself on royal jelly. Does not friend Root know that a queen can not turn herself around in a queen-cell? This being

the case, how could she get at the jelly, even if she felt disposed to do so? for the royal jelly is always in the opposite end of the cell from where the queen's head is at the time of hatching. In a few instances I have had queens, after being hatched in the Alley nursery, go back in the cell again, and all such are sure to die there, as they can not subsist on the jelly left, nor can they back out or turn around.

"Well," says some one, "how were the two queens spoken of by friend Jones kept alive?" The bees fed them, of course; and had friend J. looked closely he would have found a little hole through all that coating of wax, through which the queen put out her tongue to be fed, as I have seen them do scores of times. The longer the virgin queen is kept in the cell, the more wax is put on so as to make sure no harm shall befall the inmate from the queen, which is at liberty, biting through it. I have seen such cases several times when I have caged queens to prevent swarming, and left them caged a few days past the time for the young queen to hatch, through an oversight.

It will be remembered by some of the older readers of GLEANINGS, that ten or more years ago I had a queen laying in just three days from the time she hatched from the cell. It happened in this way: A colony lost its queen, casting a swarm with a virgin queen; and while they were hanging on a limb I opened the hive to cut the queen-cells, preparatory to returning them. Upon looking the hive over I found only one cell besides the one the queen hatched from; and as I had the frame having it on in my hands, a beautiful queen emerged from the cell. I at once took said frame (bees and all) with another, and formed a nucleus with them; and in just three days I found the queen laying. I now know how it came about, but did not then, hence it caused some to doubt. The queen was, without doubt, six or seven days past maturity when she crawled out of the cell, the bees having fed her all the while through a hole in the cell, so she was as strong and able to fly as the one that was with the swarm.

In another place in the *C. B. J.* I see friend Jones speaks of rearing queens in such strong colonies that they are so fully developed that they are ready to fly as soon as hatched. This is correct, as far as their being ready to fly; but their being thus ready to fly was because they had been kept in the cell twelve or more hours by the bees after they would naturally have hatched. After much experience and many experiments I think I can safely say that no queen can fly as soon as she emerges from the cell, where she is allowed to hatch, as soon as she is mature.

Now to the keeping of these queens in the cells, should we desire to do so. For the past two years I have been in the habit, to secure the safe hatching of every queen in the Alley nursery, of putting a little honey around the point of each cell, just where the queen would gnaw out, so she could feed herself as soon as she got a hole through (as every queen is thus supplied by the bees when she hatches in a hive, except in cases where five to twenty are allowed to hatch at will in a hive, as is sometimes the case), and in this way these queens are strong as soon as out of the cell. Carrying this plan still further: Fix a block of wood to receive the cell, in such a way that the queen can not get the lid off, but so that she can get a hole through at

one side. Against this side place a bit of sponge saturated with honey, and you have it so that the queens can stay in their cells, and become strong and ready to be fertilized, as did those spoken of in the *Canadian Bee Journal*. G. M. DOOLITTLE.

Borodino, N. Y., Aug., 1885.

Friend D., when I spoke of the royal jelly I suggested it rather off hand, as the only means of sustenance I could then think of. Since you mention it, I have recalled to mind that others have reported seeing queens thrust their tongues out of a hole, to be fed. I should be inclined to think this might account for most of the cases that have been mentioned, where queens took wing at once on emerging from the cell, were it not that we have had quite a number of reports of Holy-Land queens (not only one, but a dozen or more from the same hive), getting out of the cells and taking wing. One friend describing it said the air seemed to be full of queens, and we had almost a similar experience in our own apiary. I feel quite satisfied that young Holy-Lands often fly the moment that they emerge from the queen-cell, and I am not sure but that Italians may under some circumstances. Still, I believe it is true that they may stay in the cell several days, and possibly a week, obtaining food from the workers by thrusting out their tongues.—From the experience I have had with queen-nurseries such as you mention, it seems to me as if they should be called "Dr. Jewell Davis' queen-nursery," if we call them after anybody; but I, with many others of the friends, were led to abandon them years ago. While we are on the subject, here is something further from one of our lady friends:

HOW A YOUNG QUEEN CONFINED IN A CELL WAS FED.

I read your comments on Mr. Jones' article, "Bees confining their queen." You say you wonder they did not starve. I thought this might be the reason: As I was cutting out queen-cells in my apiary, about three weeks ago, one queen had cut a small space in the usual place for opening the cell, quite small, so she just ran her tongue out through, and two bees were feeding her. I held the frame for some time, and then cut the cap off, and she came out a splendid queen. MRS. A. McKECHNIE.

Angus, Ont., Can., August 6, 1885.

A QUEEN-HATCHER.

FRIEND ELLISON TELLS HOW HE MANAGES, AND HOW HE KEEPS QUEENS SEVERAL DAYS AFTER BEING HATCHED.

I SAW in the *Canadian Bee Journal* a notice of a queen-nursery; and not seeing any thing of the kind described in GLEANINGS lately, I thought it would not be out of place to tell your readers what a boon a nursery is to a queen-breeder. I had never used them before this year; and, very strange to say, I was just in the middle of my second year, when I saw D. A. Jones' notice. He does not give the size of the divisions in his. I have made them with two sizes of partitions—one for cells just ready to hatch, or virgin queens, and the other for laying queens. I will describe only the former in this; and if you think well I will give you a description of the other in another letter.

They both work well, and queens can be kept for ten days or two weeks with perfect safety. I made the nursery for virgin queens or queen-cells, by dividing a regular Quinby frame into 66 partitions, each $1\frac{1}{2}$ in. square, just about large enough to accommodate a single cell. One side of the frame is covered with wire cloth, while the other is composed of small doors of wire cloth, one to each partition. They are hung on small wire staples for hinges, opening up and down. When closed they are kept fast with a piece of small wire, about $\frac{3}{4}$ of an inch long, driven in half way at bottom of doors, and bent over them at right angles. Thus fastened, the queens can not get out nor bees in. After the cells are all placed in the nursery (one in each division), hang it in the center of a good strong colony. It is best to have the colony queenless, as the bees will take more care of the hatching queens which are caged. If there are nuclei ready when the cells begin to hatch, the young queens are best introduced at once; if not, the bees in a queenless colony will feed many of them for several days. In order that we may not lose any of them by starvation I prepare small pieces of old comb in this way: With a sharp knife I cut the cells all off on one side, down to their base; the cells on the other side are filled, or partly so, with honey. To do this I use a small teaspoon. The pieces are just large enough to slip into the partitions of the nursery. A little honey will last a long while, as almost every good-natured bee that crawls over the outside will hand in some honey to the caged queens. If one has to be away and is not able to attend to his queen-cells on the days he knows they will hatch, just place them on top of the bits of comb, and when the queens hatch they are safe for several days. Be careful not to have much honey running about, as the queens will get daubed; and as the bees can not get to her to clean her off, she may be lost. In the nursery for laying queens I place bees with each queen to take care of her. The above plan works well; and as many as a hundred or more can be kept for several days in one hive, and then be introduced to nuclei to be fertilized, it surely will be a great help to the queen or her owner.

I have seen queens kept in their cells by the bees, and not allowed to hatch for several days. During the swarming season, in cutting out cells before the after-swarms issue, you are more apt to find them. They are easily distinguished from queens just hatched, as they come out full fledged, ready to fly off with a swarm at first notice, and sometimes several of them will get out with a single after-swarm; and then you have to be smart to keep them from "going west." I have noticed, also, that swarms having more than one young queen are much more apt to go to the woods than those with only one; and a good many other things I have noticed, only I am afraid to write any more, as you may call this a "long letter." W. J. ELLISON.

Stateburg, S. C., Aug., 1885.

Friend E., your arrangement is substantially Dr. Jewell Davis' queen-nursery, which I have recently referred to. It was illustrated in the bee-journals years ago, and a good deal talked about. It works very well during warm summer months; especially when honey is coming in daily; but as soon as you have cool nights or a dearth of honey, all of a sudden your queen-nursery will collapse; at least, that was the experience

of a great many who gave the arrangement a pretty thorough test years ago.

ROBBERS, BREEDING QUEENS FOR QUALITY, ETC.

ROBBERS IN NEWLY UNITED COLONIES.

I UNITED three small colonies of bees a few days since, and saw with pleasure these three families, of about 20,000 each, unite in peace, making one family of 60,000. In twenty minutes thereafter I saw a bee from a fourth colony enter that hive, and it was at once seized upon as a stranger and enemy; that all these bees should have become acquainted, or have had such an individual introduction within that short time, so that a stranger should be recognized on coming among them, I thought was one of the most wonderful things, among the many wonderful things to be learned in studying and observing the operations of bees. If one of the colonies united had been red, another white, and the other blue, and the stranger from the fourth yellow, or each colony had a special perfume, as rose, heliotrope, geranium, etc., I could have at once understood how they could recognize the musk-scented stranger; but I do not believe they were so distinguished.

The question then remains,

HOW DO BEES RECOGNIZE ROBBERS?

I answer, "By their behavior." A bee enters a strange colony just as a robber enters our house, fearful of being seen, trembling, pale, by an unusual way, if possible, avoiding members of the household, and with evident intention of seizing goods and running. I think it is well known that a bee may, during a great flow of honey, by accident, in its haste enter the wrong hive, and then empty its stores, and hasten again to the field, without being disturbed, just because it never knew it was out of its own house, and therefore behaved just as others. I have found this story of the recognition of strangers in a colony one of the most interesting to visitors of my apiary.

MAILING QUEENS.

I have just received in splendid condition a Carniolan queen from Mr. Frank Benton, of Munich, Germany. There were fourteen live bees, and one dead one in the cage after at least fourteen days in the mails.

I do not believe there is any secret about Benton's success in mailing queens, further than the peculiar construction of the cage, and the covering over the food to maintain moisture.

BREEDING QUEENS FOR QUALITY.

For several years I have carefully noted different characteristics of various colonies in my apiary, and noted the races to which these colonies belonged. The first colony I noted was one which swarmed Sept. 6, 1882, and which gathered enough honey that fall to take them over to the next season, 1883, when it started out as one of my strongest colonies, showing a very prolific queen. This colony did not swarm during 1883, but stored 68 lbs. of honey in sections, and have never been seen clustered outside of the hive to this day. I have named that colony "Never Hang Out," and that name means honey. They are Holy-Lands crossed with our native drones. I have another race which in June and July, 1883, threw off five swarms, leav-

ing at last a colony queenless. They are Cypriolians.

I have another stock which I have labeled "Swarmers Stock," and which, in 1883, moved into a new hive with two stories of brood-combs and a frame of brood, and in about two weeks moved out of that again, leaving it full enough of bees to give me a surplus of over 50 lbs. of extracted honey, and about as much more from the new hive into which I placed them. In 1884, and during the present season, they have shown the same qualities—fertility of queen, and industry. Unlike the first-instanced Holy-Lands, these are often found clustering out.

I have noted the most desirable qualities in crosses between the different races decidedly the most marked, rather than in the imported stock of either race.

S. W. MORRISON, M. D.

Oxford, Pa.

I agree with you, friend M., that bees recognize robbers, at least mainly, by their behavior. Your conclusion is just the one I have arrived at after much observation and study. The point you bring out, that the progeny of certain queens have certain peculiarities which they hold *season after season*, is a very interesting one, and it seems to me to point, without question, to the fact that we may greatly improve our bees if we take pains to encourage these desirable traits, and discourage those not so desirable.

A PLEASANT REMINISCENCE.

ALSO A WORD IN FAVOR OF LAWN-MOWERS.

LAST summer, while on board a train I passed by the neatly kept apiary of Mr. Porter, of Lewistown, Ill. The nicely painted hives, arranged in regular rows, equidistant from each other, presented a very pretty picture. The streets and alleys of this miniature city were in blue-grass sod, and kept neatly trimmed by the frequent use of the lawn-mower. I consider a lawn-mower a necessary implement for use in the apiary and every well-ordered home. It is a great boon for the tired mother, when the yard or lawn is clipped short, for the children and visitors prefer it to the house; and when she is through with her work she finds her house in order, for the children have kept house, taught school, or been a visiting out of doors. A hammock and a swing should be provided for the use of little ones. A hammock hung in the shade in an apiary is a great luxury. Here the tired owner can recline, read, and watch the issuing of swarms. The most comfortable one I ever enjoyed was made from a cracker-barrel. Two holes were bored in the end of each stave, and small but stout rope was woven back and forth, using forty feet of rope, twenty for each side. Pieces of carpet were spread over the staves, and a pillow for the use of the head. I'm afraid that Mr. Root will think this savor of idleness; but there are persons to whom rest means one of the greatest economies.

I'm in hopes that the lawn-mower that Mr. Root is now offering to the public runs easily, so that a child can work it. In order to keep a lawn in order. It must be clipped as often as twice a week, during showery weather, and the older members of the family may not have time to spend in this way. If a child runs the mower, it is better to run it fifteen or twenty minutes every day, so the work will not

be so exhaustive. He will love his home much more when he takes an active part in its management. **MRS. L. HARRISON.**

Peoria, Ill., Aug., 1885.

Thanks, my good friend Mrs. H., for what you say about lawn-mowers, and also directions for making home-made hammocks. No doubt they are nice things for invalids, but I do not quite like to see them occupied by well people in the middle of the day.—Our lawn-mower is remarkably easy running—in fact, the most so of any one we have ever got hold of; and I have chosen one that cuts only ten inches wide, for the very reason you mention, that all the mowing that needs to be done may be done by the children.

CARNIOLAN BEES.

HOW MUCH THEY DIFFER FROM OUR NATIVE BEES.

IN the last issue I stated that the bees which accompanied the Carniolan queen from Germany were pitch black, fifteen of which were dead; and their bodies, as well as those of two living yet, were so contracted as to hide the bands of down, and give them a pitch-black appearance. Since then, however, some of this queen's progeny have come to light, and I now state that they are just as friend Benton described them—of a steel gray, with very marked bands of down, and they are truly fine looking. They can be distinguished at a distance from our common blacks. The queen is the best layer I have seen yet, for the short time she has been here. Friend D. A. Jones says, on page 374, Vol. II, that black and hybrid bees are found in France, Germany, Austria, Switzerland, and parts of Italy, and just across the Adriatic Sea, along the Dalmatian coast; and on both sides of the Dalmatian range of mountains there are the finest, and, he believes, the best blacks in the world. Now, Carniola lies northwest of the Adriatic sea, right north of Dalmatia, and perhaps friend Jones had reference to the black bees, called Carniolans. Would friend Jones be kind enough to reply?

Another instance of two queens in one hive. About three weeks ago I looked over my queen record to ascertain which required requeening (I clip all queens' wings in the spring, and then if any are superseded during the summer I can readily tell upon finding an unclipped one). In opening one hive to remove the old queen I found, on the first comb I took out, a young queen, and that a most splendid-looking one too. The frame was replaced, and no attention paid until the other day when my bee-neighbor, Theo. Stellwagner, was taken into my bee-yard to see the fine prolific queen received from Frank Benton. After showing him the queen, I called his attention to this fine superseded queen in the hive standing alongside my imported queen. On the first frame I took out, we found the old clipped queen. Well, this was naturally a surprise. I took out a second frame, and there was the young queen, and laying too. They were both in the hive over three weeks. I removed the old queen. **E. K. BLANCK, M. D.**

Hatfield, Pa., Aug. 6, 1885.

Very likely you are correct, friend B., in thinking that there will be no trouble in distinguishing the Carniolan from our native bees; but, how about the crosses? Can any

one tell whether a queen has met Carniolan drones or native drones? It seems to me rather unlikely. Our young Carniolan bees will be out in about a week, and then we will investigate the matter more thoroughly.

TOADS, FROGS, AND TADPOLES, OR POLLIWOGS.

SOME INTERESTING FACTS IN NATURAL HISTORY.

YOU wish to know about toads, etc. When I was a boy there were shallow ponds of water in some old stone-quarries close to our house, and every spring there were millions of toads raised there if the water did not dry up before their legs grew. This used to happen sometimes, and then there were a great many deaths in a small space. I have observed a great many of their habits. First, the toads' eggs are laid in long lines about as large as a clay pipestem, and they are strung around the pond in every direction until the whole surface is covered. This made the scum you saw on your carp pond; but if you had tried to skim it off you would have found it to be like the rolls our mothers used to spin the yarn, from which our stockings were made; viz., all in a bunch, but all separate pieces, only the difference would be that the rolls were about 2 ft. long, and the strings of eggs are perhaps 200 ft. long, with an egg about every $\frac{1}{4}$ inch. After they hatch they remain in and around the lines for a little time, and then go to the edge of the pond, where they soon grow some very small legs, and soon after lose their tails, and come out of the water small toads, and bid farewell to water, until in time they return to lay their eggs (for the toad is not a water-bird).

Frogs are somewhat different. If you had looked closely you would have seen a large bunch of something that looked like jelly, about as large as your head, and quivering in the water about like a lump of jelly. It is usually attached to some old dry grass or rushes if there are any in the pond; if not, then floating in the water. It is not like the toads' eggs, however, as it is all in a mass, and can't be separated like them; they are also laid some days earlier in the season; and instead of getting out and hopping off as the toads do when they are small, the young frogs remain in the water in the polliwog form until the next season. They are then about 2 inches long, and these were the ones you saw, but they were last year's ones, and not those coming out of the same batch of eggs from which the toads came. **E. M. JOHNSON.**

Mentor, O.

Friend J., with your explanation I can now understand the matter readily. Early in the spring I saw those long threads of eggs, and there were such quantities of them that I thought once about raking them off from the surface of the water and destroying them. In fact, there was a perfect network of these strings all around on the outside of the pond. We also saw the eggs of frogs as you describe them; and so when they hatched out we had toads and frogs mixed up together; and when they got legs, the toad portion of the crowd hopped off and went away to the woods, as I have told you, while the frogs, most of them, stayed in the

pond. But, are you not mistaken, friend J., in saying that the frogs do not get out of the polliwog state until the next season? I should say, that tadpoles all turn into frogs during the spring months of the year.

A REPORT OF THE HONEY SEASON IN THE SOUTH FOR 1884 AND 1885.

ALSO SOMETHING IN REGARD TO DEAD BROOD WHICH AFFECTED TEN DIFFERENT APIARIES.

INCLOSED you will find the condensed report of ten apiaries for 1884, which makes a very fair showing for that year. In the alluvial lands the yield of honey was moderately fair; but in the uplands, owing to the drought, there was scarcely enough made to carry the bees through the winter. Bro. Haniman's apiary is located in the Bayou Macon hills, one mile from the Mississippi swamp. His short crop was the result of so much hill range.

REPORT OF APIARIES FOR 1884.

O. M. Blanton, Greenville, Miss.* Colonies, spring count, 275; fall count, 380; lbs. of honey per col., 75. Blanton & Vaught, Refuge, Miss.† Colonies, spring count, 41; fall count, 80; lbs. honey per col., 110.

F. S. Elder, near Lake Village, Ark. Col's, spring count, 56; fall count, 74; lbs. honey per col., 140.

H. Ramus, Lake View, Ark. Col's, spring count, 43; fall count, 71; lbs. honey per col., 153.

Alfred Saunders, Luna, Ark. Col's, spring count, 40; fall count, 85; lbs. honey per col., 137.

H. A. Haniman, Grand Lake, Ark.‡ Col's, spring count, 105; fall count, 135; lbs. honey per col., 65.

Chas. Kincade, Sterling, Ark. Col's, spring count, 95; fall count, 96; lbs. honey per col., 111.

Victor Johnson, Lake Port, Ark. Col's, spring count, 20; fall count, 40; lbs. honey per col., 250.

Robert J. Adams, Lake Port, Ark. Col's, spring count, 95; fall count, 190; lbs. honey per col., 173.

Wm. McLendon, Lake Village, Ark. Col's, spring count, 90; fall count, 180; lbs. honey per col., 116.

Average per colony, 133 lbs.

This season opened with any thing but flattering prospects. There was no honey gathered after the 25th of August last year, and from that time until April the bees were consuming their stores. Our winter was very severe for this climate, and we had a very cold wet April, and but little honey was gathered until May. I commenced extracting the first of June. The colonies were so weak from short stores, it required a long time for them to build up strong enough for surplus. June and July were moderately fair honey months, with much dry weather. Within the last few days we have had heavy showers, and the prospects for August are very good from swamp woodbine, bonaset, cow-peas, and button-bush. From about 395 colonies, spring count, I have extracted to date only 17,000 lbs. You will find that the Southern crop of honey will be decidedly short.

You seem to think the long legs of my 20-frame one-story hives, shown in the bird's-eye view of my apiary, were intended for the overflow. Nothing of the kind has occurred in this locality for the last forty years, owing to our substantial levees (embankments). I assure you they are for comfort when at work, as they are 30 inches from the bottom of the hive to the ground; which is the proper height for a man of my size. The double stands for

my two-story Simplicity hives are 20 inches from the ground. I prefer them for one hive, as you can stand on either side of them, and will hereafter cut the stands in two.

DEAD BROOD.

Last year, about the first of June one of my neighbors, Mr. S. C. Vaught, discovered dead brood in his apiary. It first commenced with the capped brood, but soon extended to the larvæ, which, in some instances, in both soon became decomposed. On examination I found some of the capped brood with minute holes in the cappings, and the decomposition complete. Some of the pupæ just dead, I found reversed in their cells. There was a very disagreeable odor from the decayed brood, but not such as described in articles on foul brood. Upon inquiry I found ten apiaries, within a radius of 15 miles of me, affected by it; some to the extent of 15 per cent, and most of it confined to the capped brood. Two colonies in my home apiary were affected slightly. The Refuge apiary, with its bright new combs, had it in every colony, but did not reach putrefaction before the bees removed the dead, and filled the cells with honey, and the queen commenced laying as vigorously as ever.

Mr. Vaught's apiary of about 250 colonies was so badly diseased that he determined to let them work out their own salvation, which they did. I uncapped the dead pupæ of some colonies, and the bees soon cleaned the cells.

Just before the discovery of this condition of things the bees gathered a great deal of dark sour honey-dew (aphides'), and I attribute the disease to that cause. This year, as far as I can learn, there is no evidence of the disease. It certainly can not be the forerunner of foul brood, or we should have it this year.

O. M. BLANTON.

Greenville, Miss., Aug. 4, 1885.

Thanks, friend B., for the valuable facts you furnish. I sincerely hope it may so transpire that the trouble you mention with dead brood was caused by the sour honey you speak of; and I think you show excellent good sense in investigating the matter before rushing to the conclusion that you have foul brood in your neighborhood. The fact that it disappeared of itself, I should think, is pretty nearly conclusive evidence. Did anybody ever hear of foul brood disappearing of its own accord? There has never been such a report made, that I know of.

MORE ABOUT BONE-CHARCOAL FOR PURIFYING HONEY.

BEE-PASTURAGE IN NORTH CAROLINA.

IN reference to the note of Chas. H. Grote, page 388, I think the idea is a most valuable one, and that bone-black, or animal charcoal, could be used to change the color of dark honey just as easily as it takes the color from the syrup in sugar-refineries. Enormous quantities of bone-charcoal are used in sugar-refineries for clearing the syrup, and why should it not clear honey? The bone-black is easily procured. No doubt that Chas. F. Mapes, of Front St., New York, who purchases large quantities of spent bone-black, would tell your readers where they could procure the fresh article. All that is to be done is to fill a tall narrow tubular filter with the black, and run the honey through it. An experiment could be made at a very small cost,

*Lost 50 swarms from careless assistants whilst attending Refuge apiary.

†Bought apiary 14th of June, and then transferred from old gums, by Heddon's method.

‡Judge Haniman's apiary can not be classed as swamp location, as it is on a brow of hills.

I wish some of your readers could see the profusion of bee-food going to waste in this beautiful mountain country. Just now we have the locust, basswood, white fringe, white clover, kalmia, azalea, calycanthus, and I can not tell you how many other shrubs and trees in bloom, while the silver-bell, red-bud, cherry, plum, thorn, and a number of others, are past bloom. We have a profusion of flowers all through the summer. The sourwood is especially abundant, and so are the magnolia and tulip trees. Indeed, this country is flowing with honey, and there is room for thousands of hives, and water is everywhere—pure, cool, running streams filled with brook trout, and yet the bee-keepers have nothing but old half-rotten “gums” for the bees. I have been telling the folks here about your Simplicity hives and the honey-boxes, and they see the point; but it needs more enterprise than the natives have been used to, to gather in all these lavish stores. No winter housing wanted here, where the witch-hazel is in bloom in February.

HENRY STEWART.

Webster, N. C., June 4, 1885.

Now, then, are some of our readers so situated that they can test this matter of filtering honey through animal charcoal? Will the honey go through without diluting, or how thick is the sugar syrup when it is passed through the animal charcoal? Who can tell us more about it?

REPORT FROM CALIFORNIA, BY OUR OLD FRIEND GALLUP.

HONEY BY THE TON; ALSO SOMETHING IN REGARD TO IMPORTATION OF QUEENS.

EDITOR OF GLEANINGS:—I have been up into the mountains for a short time with the bee-keepers, and have taken a few notes. One has taken out three tons, one six tons, one eight tons, one fifteen tons, etc. The season has been quite unfavorable. Mr. S. T. Miller has all together on hand now, between sixty and sixty-five tons. He held over about fifty tons last year, and he has some fifteen tons of this year's crop. He has 275 stands of bees, and they are kept in splendid condition. Mr. Miller had quite an experience in getting queens direct from Italy. He ordered from Chas. Bianconcini, I think; the first eight were all dead, and of the next fourteen, five were alive, but two were so feeble that they did not live. They came by express, so the three living queens were quite expensive. Mr. B. can not see why they should arrive safely to you and others east, and not here. He can not or does not understand that they have to be some eight days longer on the road, and have to pass over a hot, arid desert, and then be carried thirty miles over a rough mountain road. The fact was, they consumed all their food, and perished by starvation.

DR. E. GALLUP.

Tustin City, Cal., Aug. 8, 1885.

Thanks, friend G., for your excellent report from California. In regard to the matter of importing queens from Italy, we have had more die from starvation than from any other one cause. It seems to me that friend Bianconcini has no method of getting at the exact number of bees he puts into a cage. The stores would be all right, if the quantity of bees is not too great. I would suggest

that he weigh out his young bees, or, if it would not be too expensive, count them out, and then weigh the quantity of food. To put in very much more food than is needed is not desirable, because it adds so very much more to the express charges. I think our friend Charley will succeed, though, for he is a pretty careful man, as a general thing. You know he has sent us pretty good-sized importations, with the loss of hardly a single queen. I should like to know how your bees from these imported queens compare with the others, in regard to working qualities, in California.

REPORT OF A NUCLEUS IN FLORIDA.

ALSO SOME FACTS ABOUT FLORIDA IN GENERAL.

ICAME here last November and brought with me a one-frame nucleus with a pure Italian queen. My location was fixed before I left home, hence I had not the privilege of looking up a place producing the most honey-plants. My little grove, containing upward of one hundred trees, has about forty which bore some last year, and are bearing more this year. Some have over one hundred oranges on, while others have only a few. These have been budded about four and one-half years. I brought the bees with me to see what they could do in this locality. In a short time after my arrival they commenced gathering honey and pollen, and kept themselves in feed, and reared brood up to Jan. 10, when I thought it time to begin feeding to strengthen them up more rapidly for the orange-bloom. I do not know whether they would have kept themselves in honey during the latter part of January and the fore part of February or not, as it was colder and more cloudy. I shall know more about it next winter.

When the oranges came in bloom they had three frames filled with brood and honey. I had another frame of empty comb, and gave it to them. When the orange-bloom was gone they had increased to ten frames filled with honey and brood, and threw out a good swarm.

Orange-groves are numerous in this section, and bees gather more honey from them than I had thought. I believe a colony will gather as much honey from orange in this locality as from white clover in Ohio.

A few weeks after orange-bloom was gone, saw-palmetto blossomed. This plant grows on flat ground and in low places. In this immediate vicinity it is scattering, and bunches of it only here and there. But it grows in abundance in the “flat wood” which is two and a half miles from me. I suppose my bees do go there, but I wish I were one and a half miles nearer. The bee-man in this locality—near Orlando—will get his surplus honey from orange and saw-palmetto; and I am reliably informed that goldenrod and other wild flowers will furnish honey enough to keep the bees the entire year through. Anyhow, I have confidence enough to want an apiary, and am increasing as fast as I can, with the expectation of supporting myself by my bees until the oranges come into full bearing. I intend to keep only Italians, and am rearing my own queens. One week I lost three out of five; think the bee-martins took them. Some call them “mosquito-hawks,” I think. When bees hang out at the entrance at night, toads eat them. I have

killed as many as four by one hive at one time. I have purchased one Italian colony, and with this and the Italians I already have I rear my queens to Italianize the black colonies, which I buy near here at \$3.25 each.

Bees gather honey and pollen now only in the morning, and I am increasing with sugar. We are having solid hot weather now—thermometer gets into the nineties every day; generally about 95 to 98°. The hottest it has been this summer was 105° in the shade. When I get more bees and more experience in the business in this country, I will send you another report. L. W. GRAY.

Troy, Orange Co., Fla., July 21, 1885.

THE BEE-KEEPERS' PHOTOGRAPH.

A LIST NOW NEARLY COMPLETE, OF THE FRIENDS WHOSE PICTURES APPEAR IN THE PHOTOGRAPH MEDLEY OF THE NEW-ORLEANS BEE-KEEPERS' CONGRESS.

FRIEND ROOT:—I see in GLEANINGS of August 1st a suggestion from Dr. Roberts, in regard to numbering the faces in the N. O. photograph. I think it would be better to begin in the upper left-hand corner as we look at it; that being the way we read, it will come more natural. To aid this numbering and naming, I send the inclosed list. I hope we shall have better success than Dr. R. has had thus far, as he has named only two, and one of those wrongly. It is our friend P. J. Christians, of New Orleans, the cashier of this business, who sits next to friend Viallon, of Bayou Goula, La.

(Top row, beginning at the left.)

- No. 1, Judge W. H. Andrews, McKinney, Texas.
- No. 2, J. G. A. Wallace, Brighton, Ontario.
- No. 3, Dr. D. McKenzie, Carrollton, La.
- No. 4, Ernest R. Root, Medina, Ohio.
- No. 5, Oscar F. Blesloe, Grenada, Miss.
- No. 6, C. M. Bliss, Fox Lake, Wis.
- No. 7, R. Grimsell, Baden, Mo.
- No. 8, George Vincent, 63 Decatur St., New Orleans, La.

(Beginning second row on upper left hand corner.)

- No. 9, O. R. Flournoy, San Antonio, Texas.
- No. 10, Thomas F. Kerr, San Antonio, Texas.
- No. 11, L. Johnson, Walton, Ky.
- No. 12, Dr. D. R. Fox, Jesuit's Bend, La.
- No. 13, Mrs. F. E. Peters, Shelby, Mo.
- No. 14, F. E. Peters, Shelby, Mo.
- No. 15, Mrs. Lucinda Harrison, Peoria, Ill.
- No. 16, Mrs. S. J. T. Moore, Monroe, La.
- No. 17, Mrs. C. M. Bliss, Fox Lake, Wis.
- No. 18, Mrs. Dr. J. Oren, Laporte City, Iowa.
- No. 19, Dr. Jesse Oren, Laporte City, Iowa.
- No. 20, Sylvester Johnson, Irvington, Ind.

(Third, or middle line, beginning on left.)

- No. 21, J. W. Park, Columbia, Texas.
- No. 22, Amos Abrams, Benton, La.
- No. 23, Col. O. M. Blanton, Greenville, Miss.
- No. 24, C. Grinn, Jefferson, Wis.
- No. 25, J. B. Mason, Mechanics Falls, Maine.
- No. 26, W. S. Hart, Hawk's Park, Fla.
- No. 27, H. C. Austin, Austin Springs, Tenn.
- No. 28, C. F. Muth, Cincinnati, Ohio.
- No. 29, Dr. J. W. Hudson, Mayville, S. C.
- No. 30, S. W. Salisbury, Kansas City, Mo.

(Fourth line, left hand.)

- No. 31, J. A. Schudemayer, Black Jack Springs, Texas.
- No. 32, J. W. Winder, Carrollton, La.
- No. 33, Dr. J. P. H. Brown, Augusta, Ga.
- No. 34, Dr. W. F. Roberts, Clinton, La.
- No. 35, S. C. Boylston, Charleston, S. C.
- No. 36, J. A. Green, Dayton, Ill.

(Lower line, left hand.)

- No. 37, J. M. Killough, San Marcos, Texas.
- No. 38, B. F. Carroll, Dresden, Texas.
- No. 39, James Forncrook, Watertown, Wis.
- No. 40, Thomas G. Newton, Chicago, Ill.
- No. 41, A. I. Root, Medina, Ohio.
- No. 42, P. J. Christians, New Orleans, La.
- No. 43, P. L. Viallon, Bayou Goula, La.

From 75 colonies in the spring, I have to report 40 increase and 6.0 lbs. of honey. My bees on gray land failed to store any honey during horsemint bloom, while those on black land, only 13 miles away, did well. Gray land has made a partial fail-

ure in honey throughout this section, so far as I can learn.

7—O. R. FLOURNOY, 75—115.

San Antonio, Tex., Aug. 10, 1885.

Thanks, friend F. I think your plan will be the most practicable one; and if some one will supply the names for the missing numbers, we shall not need to devote any more space to the subject.

PREVENTING AFTER-SWARMS.

MORE ABOUT FRIEND HEDDON'S METHOD.

AFTER reading the last issue of GLEANINGS it seems to me that justice to myself and your readers calls for a few more words from me, upon this interesting and important subject.

In regard to my method as given in a former issue, and discussed by Mr. Doolittle on page 556, I think I never laid it down as infallible, though I do not now recall to mind a single case of failure in my practice. It seems that others are not all meeting with the same success that has crowned my efforts in the direction of preventing after-swarms without even opening a hive.

There are, no doubt, two ways to account for this great variance regarding the reports concerning success with the method. It may be accounted for by a difference of locality; and, again, by difference of manipulation. All systems of manipulation do not give us the same results in all locations. When I read Mr. Doolittle's method of introducing virgin queens, my mind pictured the same disastrous results as are described by Mr. Ellison, should I attempt to apply it in my apiary. I am, however, of the opinion that the cause of failure on the part of the few who have failed, is *mostly* owing to their lack of performing the work in keeping with the spirit of the method. I presume I neglected to be explicit enough in describing it, or forgot something, the same as I forgot to add the extracting of the old combs, in the concluding sentence of my article on modern transferring, on page 562. Several have reported success in "Preventing after-swarms," by simply hiving the prime swarm on the old stand, and removing the old hive to a new location. They claimed the cause of success to rest in the fact that this removal drained the old hive of a larger proportion of its bees, especially the older portion; and so when the young queens came to hatch, the bees would find themselves too few in numbers to swarm, and all supernumerary queens would be destroyed, and thus no after-swarming would take place. The theory is correct, but I found that it did not go far enough to insure success. I added to it letting the old colony remain, practically upon the old stand with the swarm; and just before the queens were ready to hatch, *then* remove the old colony to another stand, and thus deprive it of its flying bees; and then what is left to swarm, except queens? Under such conditions, how could they swarm?

Is it not evident, that those who have failed have not done their work so as to secure these conditions? Have they bees that cast prime swarms, ten to fourteen days before the queens begin to hatch, rather than seven days before? Then they must not move the old colony so soon after prime swarming. But some one says, "No. My colony cast their second swarm the next day after they were removed to their permanent location."

Well, whence did that colony get bees to swarm with? Did you follow our injunctions, to remove the old hive, when nearly all its field-working force was out? Did you remove it carefully, so that as few bees as possible would mark the new location? If so, whence did they get the bees with which to make up a swarm? If your operations were all in keeping with the spirit of this method, then your bees must have different habits from mine. I could not be persuaded to adopt Bro. Doolittle's additions to my method of preventing after-swarms, even if I needed any, for they are not in harmony with the method; for it is one adapted to him who has hundreds of colonies to handle, and does not wish to spend more time in manipulating the old colony than it requires to hive the second swarm beside the old stand; and after both queens are fertile, remove one, and run back the swarm, which is another plan of ours, which settles the question of increase from second swarms, and one which we often practice if the colony is one that we wish to rear queens from.

This puts me in mind of one instance this season, where one of our best colonies that had cast a prime swarm nine days previously, cast four after-swarms in as many days, all of which we hived on fdn. in hives, clustering about the old stand. As soon as all of the five queens were fertile, we shipped four of them and ran all the swarms back into the old colony, extracted all honey stored in the newly drawn combs, and gave their combs, eggs, and larvae to prime swarms just issuing. Not a particle of bee labor or time was lost. We spent less time in the whole operation, than I have seen spent in trying to "clip all the cells but one," and then failing to prevent after-swarms at that.

Our climates and localities, as well as our ideas of dispatch, differ widely. I could no more adopt Mr. Doolittle's box and comb manipulation than I could his hive. I do not think any one will tolerate any added complication, when once he "gets the hang" of just how to use my method in its letter and spirit.

JAMES HEDDON.

Dowagiac, Mich.

FALSE STATEMENTS IN REGARD TO THE HONEY BUSINESS OF OUR COUNTRY.

As a protection to our bee-keeping population, we propose in this department to publish the names of newspapers that persist in publishing false statements in regard to the purity of honey which we as bee-keepers put on the market.

WE extract the following from the *Evening News*, of Saginaw, Mich. It was evidently written by our old friend L. C. Whiting, of East Saginaw, Mich.

BEEES AND GLUCOSE.

I saw an extract in your paper from the *Chicago News*, headed, "What Bees are Coming to." They took it originally from the *Detroit Free Press*. It was written in the style of Peck's bad boy, and was evidently a burlesque, or something worse, on the part of the author. For instance, the writer said the bees were being fed glucose; and to prove it pointed out a barrel labeled grape sugar. Now, grape sugar, if dissolved, would turn back into sugar again before he had time to sell it, and would not be the color of honey, and of course be unsalable. To a bee-keeper the case if there was any truth in it at all stands like this: Bees as a rule raise brood only when honey is coming in. There is a time in the summer, after white clover has gone to seed, that there are no flowers to yield honey for several weeks. Bee-keepers have learned that it pays to feed back poor honey during this

dearth of blossoms, to keep the queen laying to raise workers to gather the honey that comes later. This is probably what the *Detroit* bee-keeper was doing. The life of a working bee in the honey season is very short, from sixty to ninety days. If the flow of honey ceases for thirty days nearly half the bees in the hive will have died from old age. Those unacquainted with the short life of the worker-bee think some disease has killed them. Bee-keepers feel, after such a winter as the last, that they have about enough to contend with without being advertised as selling glucose for honey. We some time will have a law that will compel persons to sell things for what they are, or forfeit their goods; and the sooner the better. L. C. W.

It is indeed true, that bee-keepers have had enough to contend with without this miserable sensational reporter's story that friend W. refers to; and it seems to me that the times are ripe for a law that will make it a very severe offense to sell any thing for something else. Feeding bees something that is not honey, with the purpose of selling it for honey, if such a thing has been done, should most assuredly come under the above head.

LETTER FROM J. H. MARTIN.

He tells how his Automatic Extractor works.

ALSO SOMETHING ABOUT VIRGIN QUEENS.

YOU call for a report from some one using the Stanley automatic honey-extractor. I have used one two years, and not only extracted one ton, but several, with it, and the following is my report. As to the working qualities of the machine in my yard: Last season, owing to the short crop, our work with it was limited to about one ton; but this season basswood came down in such a shower that nearly three tons have been run through the machine, and we are not through yet.

The machine I ordered of Mr. Stanley was made to fit my size of frame, 11x14. It was among the first of his make; and by the side of my old two-frame machine it was a genuine "Jumbo." It takes four frames, and, of course, it does not start off so quickly nor stop so easily as the light two-frame machine, and on that account it appears clumsy to manage; but after you get used to the change, this clumsiness disappears. As I have done nearly all of my extracting myself, my method is as follows:

I go out into the yard with my cart, upon which I have three hive-bodies. I go from one hive to another till I fill all of the hives, say 30 frames of honey. I then wheel it right into the building, close to the extractor, and extract the load. After uncapping four frames I insert them in the extractor, and, whirling the baskets into position, I give the crank a few vigorous turns, and then leave the machine to run down. It will run with enough force to throw out honey until you uncap another frame (I have sometimes uncapped two frames). I then reverse the combs and set it to whirling the other way, and uncapp more combs; and by the time the machine stops I have four more combs ready to extract.

The beauty of the machine, and the great claim for it, is the reversing motion, and it works to a charm. You don't have to touch a sticky comb until both sides are extracted; and if you do your own work, the machine is not only automatic in reversing, but in extracting; and I think Bro. Heddon

would find it so without slipping the crank out of gear. The gearing on this machine could be fixed in a short time so as to be so used.

The only fault I find with my machine is in the comb-baskets. As my frame is deeper than the L. frame, the wire cloth would bulge out and break the combs. I put in several stays, and it now works all right. I also had to get stronger chains to strengthen the baskets where they are attached to them. I wrote to friend Stanley about this weakness in the machine, and his reply was that I must turn slower. My reply was, that unless he could make his machine strong enough to be run like lightning it wouldn't suit me and a great many other bee-keepers. I understand the machines have been made stronger, and somewhat improved, this season.

I have not run it to test its capacity. With the aid of a ten-year-old boy I have run out 1000 lbs. in about 7 hours. That was as fast as I could bring it in and uncap it. To run it up to its full capacity would require two men in the yard and two or three to uncap, and one at the crank.

I will sum up my opinion of the automatic honey-extractor, by saying that I wouldn't exchange it for the old two-frame machine again. I have a two-frame machine in my Granville apiary; and if I run that apiary for extracted honey I shall surely put in a Stanley machine; or if I should go to Florida or California or Cuba, and run for extracted honey, I would order a Stanley. I will also say, that I am in no way interested in Mr. Stanley's business. I met the gentleman at the N. E. N. Y. Association, and found him a very agreeable young man, and I have no doubt any one dealing with him will be fairly treated.

INTRODUCING VIRGIN QUEENS.

The question of introducing virgin queens is of great interest to me, and I have been in hopes a reliable method could be discovered, or one that is sure every time. I succeeded several times by mixing bees in Doolittle's cage, and thought I had got it sure, when the bees went back on me and killed several fine queens. At the same time three fertile queens were balled in a cage, and one killed. I attributed this to the age of the bees used. I formed several cages of bees for nuclei while I was extracting, and I shook bees from the top story. I seemed to get bees all of the same age, while bees from the brood-frames give you bees of all ages, and are better for forming nuclei, and will accept a queen nearly every time.

I have accidentally hit upon a plan that is quite sure, or has been with me so far. I formed a nucleus with a mixed lot of bees, and gave them a virgin queen. In a few hours I happened to look into the cage, and the bees were balling the queen on the bottom of the cage. I was somewhat provoked at the bees; and seeing a pail of water standing close by I thought a bath would do the bees good. So I dipped the cage, bees and all, into the water. They looked very much as though they had been out in a wet rain, and I set them up in the sun to dry. When dry I put them in the hive, and the queen was accepted. Now, Bro. Israel, next time you climb the mountain and roll your bees around, get a stream of water handy, and roll them through that, and you have the whole process.

Virgin queens can be quite successfully introduced with Alley's cage, and I should think Boomhower's cage would also answer admirably; but they are not sure every time. As far as my experi-

ence goes, a virgin queen will be accepted when she gnaws herself out of a cell, even if the cell has been in the hive but a short time. If an artificial cell could be constructed so the queen can gnaw herself out, or with an adjustable cap to open gradually, I think the queen would be accepted every time.

JOHN H. MARTIN.

Hartford, N. Y., Aug. 5, 1885.

Friend M., we are much obliged to you for your report, and are glad to hear of your having such a good yield of honey. Some one has before suggested the plan of starting the extractor under high motion, and letting it stop when it got ready. I believe it was friend Heddon. Although I examined one of the automatic extractors, I can not now remember whether it was geared or not; but from what experience I have had with four-frame extractors, my opinion is they do not need gearing—simply put a crank on top of the shaft.—In regard to the bath remedy as a cure for balling queens, it does not always work. I have had stubborn nuclei that would pitch into the queen again before they got hardly dry; although, as a rule, "sousing" them in water generally diverts their attention from the queen. My experience in caging virgin queens was, that the cage was a nuisance, and we got along much better without any cage. Why should they be caged, if they are entirely unmolested without caging? If you mean virgin queens five or six days old, you will perhaps want a cage; but as a rule you will waste more time, both of your own and that of the bees, than your old virgin queens are worth; that is, that was my conclusion.—I am sorry to discourage anybody; but the artificial-queen-cell business has been pretty thoroughly tested. One friend went so far as to advertise them for sale several years ago; but, like all other plans for introducing, sometimes it worked and then again it didn't; and the "didn'ts" came so often that it spoiled it all.

GRADING HONEY BEFORE YOU TAKE IT TO MARKET.

ALSO SOME GENERAL REMARKS IN REGARD TO GRADING FARM PRODUCE.

A FEW days ago we purchased a lot of Red-Astrakhan apples of a farmer. When we take honey around town on our wagon, we take along fruits and vegetables also, more or less, and the Red Astrakhans were put on the wagon. We decided that we should have to have 15 cts. per peck, to cover cost, and expense of selling. The sales were slow, because customers were deterred from buying by bruised, specked, and gnarly specimens of fruit scattered all through. Finally the boys stopped the wagon, and picked out all the poor fruit, and put it into a basket by itself, showing customers nothing but fair, smooth apples. The load was closed out at 20 cts. a peck, in a very short time. Now, how many bad ones were left, do you suppose? In grading they got about one peck of bad ones to five pecks of perfect fruit, and they sold this bad peck for 10 cts. Do you see the point? Six pecks of apples brought \$1.10 after they were graded. Before grading they offered six pecks of apples for 90 cents,

and could not get it; therefore it would have been good economy to have poured the bad apples out to the pigs, rather than to have damaged and hindered the sale of the nice ones by having them sprinkled through with bad ones. I was a little surprised when they told me about it; so I asked my wife one day, when I saw her paring apples,—

"Sue, how much more would you give to have apples that were all smooth, without any specks, rotten spots, or 'crookedness' about them—that is, providing you wanted them to cut up for pies or sauce?"

She replied promptly,—

"Why, I would give twice as much."

"Oh, no! you couldn't give so much as that, could you? Are you not putting it a little too strongly?"

"I am not putting it too strongly at all. Where a woman's time is valuable, and where she likes to have things nice, she can well afford to give *double the money* to get nice fair fruit."

Of course, there are people who will want the culls at a moderate price, and such people should have the privilege of having them. Now, we have kept on grading our fruit ever since that day, and I have been surprised again by hearing the boys say they could not get rid of their culls so long as they had nice fruit on the wagon. There was hardly anybody who wanted the culls at any price. While relating the little story to a friend, he mentioned the following:

He wanted to buy some corn, and a farmer drove past his house with a load that he wanted 20 cts. for; but there were so many nubbins and so much soft corn mixed in with it that he decided not to buy it. Shortly afterward he drove to Akron (five miles), and met the same farmer who was trying to sell his corn. He drove from place to place, but the soft corn and the nubbins frightened his customers, and he could not get a purchaser. He finally sold it to my friend (who offered him 20 cts. in the morning), for only 15 cents per bushel. They transferred it from one wagon to the other; but while so doing they sorted it, throwing the bad ears to the back end of the wagon. After they got it sorted a man drove past who wanted to buy corn, and he offered 25 cts. a bushel for the best. Now, then, how many bushels of bad corn were in the back end of the wagon? I can not remember the figures, but the result was something like this: There were 17 bushels of good corn and 3 bushels of culls. The farmer sold the 20 bushels for \$3.00. My friend who bought it was offered \$4.25 for the sound corn after he got it sorted, and had the culls to take home besides. I have mentioned this little story a great many times, and every one verifies it.

Our friend Terry, of potato-book fame, has several thousand bushels of potatoes, not very large, on account of the devastating blight that has swept over almost all of Northern Ohio. I suggested that he sort them, and sell the small ones for what he could get, and the nice ones at a good price. He was afraid it would not work with the potatoes. When I got home I asked my wife if she would give double the money for good-sized potatoes in good shape, free from

specks, crookedness, etc. She replied at once, that she would gladly. Now, I do not know how far it pays to carry this principle. Perhaps my wife is a little over particular, in her readiness to pay a good price for fruits and vegetables that are just to her liking; but I know there are lots of women-folks who are just like her.

Now let us apply it to honey. Some of your honey is real nice; a good deal of it is pretty fair, and some is crooked and unsightly; but it is not well to put it together, with the hope that the purchaser won't mind the bad if there is not very much of it, and your chance of getting a fancy price for your fancy honey is killed by a few bad sections mixed in, just as we drove customers away from our apples, and just as the farmer made his whole load of corn unsalable by three bushels of soft nubbins mixed in. It is the same thing with liquid honey. There will probably be some time in the season when honey that comes in is just splendid. Put this by itself; when the yield changes, put this by itself, and put the poorest by itself. When you have a customer who will give any thing like a fair price for the poorest quality, let it go. You will always have the most trouble in selling the culls—at least, we do on our market wagon. People have different tastes and notions. There are good many nowadays in every community who take pleasure in using and in showing to their friends, God's finest gifts to men. They like gilt-edge butter, and they enjoy paying a gilt-edge price for it. It stimulates and encourages the producer, and raises farming, fruit-growing, etc., to one of the fine arts.

A great many purchasers spoil God's finest gifts by bungling, slipshod habits in handling the products, after nature has furnished them free from blemish. Almost every farmer who brings us apples puts them in bags. Very often the bags have had flour or meal in them; they are dumped into the wagon, then shaken into a basket. By the time we get them they have to be sorted and wiped. Wiping takes off the bloom, which everybody loves to see. Another thing: A good many apple-growers shake their apples off on to the ground, and perhaps set their boots on them when they are picking them up. A few days ago a young man brought us some beautiful Red-Astrakhan apples that were picked from the trees, and laid carefully into baskets. I gave him some new baskets in place of his, so that we were enabled to handle the apples without touching them or tumbling them from one measure to another. The man who raised them is president of one of our horticultural societies. Did it pay him to pick the apples? They brought fully 20 c. more than if he had shaken them off, and everybody was pleased all around. If we could have all the fall apples brought us picked in this way, and set into our market wagon, nicely graded by the picker, wouldn't it be fun to sell fruit? The careful housewife could then fill the fruit-stand with these great smooth beauties, with the bloom on every apple that it possessed when it ripened on the tree. Now, dear friends, does this little chapter strike home to you in your work?

HEADS OF GRAIN FROM DIFFERENT FIELDS.

ANOTHER WAY TO CLEAN THE CLARK SMOKER.

THAT smoker I bought of you was in good health; but in the run of time it became badly affected with the quinsy; and, as the Frenchman said by the bellows horse, it went "ove heze, ove heze." I gave temporary relief by pushing and pulling a square hickory stick through its windpipe, turning the stick at the same time; but the glue-like soot gathered and settled on and on, until its lungs ceased to work. I then took it to my work-bench and performed a surgical operation by making a hole slanting through in the bottom-board of the bellows, in the direction of the back end of the air-tube, leading from the bellows to the fire-pot. I then wound a strip of thin new domestic around my hickory stick, and swabbed and cleaned out this badly choked tube precisely as a deer-killer cleans out his rifle. I first opened the tube with my brace and a small bit, by carefully working the bit in at each end of the tube. This hole in the bellows-board I stopped with a little ball of soft beeswax. I made it airtight in half a minute, and can open it in that length of time.

I will suggest that you make the tube leading from the bellows to the fire pot *straight*, and solder one end near the nose of the fire-pot, and let the other extend back, accessible through the hole in the bottom-board. A bellows constructed in this way can be cleaned by a child, with a swab and pan of water, I think, in a few minutes.

Quitman, Texas.

J. M. STEDMAN.

Thanks, friend S. Your suggestion in regard to stopping the hole with a piece of soft beeswax, is ingenious and valuable. This would make the opening absolutely airtight, quickly done and almost no expense.—You can not make a straight tube send the blast straight out at the nozzle of the smoker. On this account I think we had better have it bent; but we may adopt your plan of leaving an opening for swabbing out.

YELLOW-JESSAMINE HONEY NOT INJURIOUS WHEN FULLY RIPE, BUT THE UNSEALED POISONOUS.

This honey is considered poisonous if eaten before it is ripe, or capped over, among our people in Eastern North Carolina, where it abounds all over the woods in large quantities. Of this I can remember being told ever since I was quite small; and I have heard of many instances where people were made sick and partially *blind* from eating unripe jessamine honey; and in consequence of this, all our box hive men are very careful to save no honey in the comb, except that capped—all uncapped being squeezed out, which is supposed to work off all impurities in it, after standing a few days, on being squeezed out.

COTTON AS A HONEY-PLANT.

Bees are just booming on the cotton honey-flow at this time. Italians, albinos, and Syrians, all go for it with a vim this year. You know I reported last season the extra yield of cotton honey from one hybrid colony of Syrians, while Italians were lying idle; but it is not so this year. The albinos seem to like it better than either Italians or Syrians, though all of them are filling every available nook and corner with it.

CATCHING AND CAGING QUEENS.

If bee-keepers would use a queen-catcher, something like the "Klinitz" catcher, there would be fewer queens lost by cramping and otherwise injuring them by picking them up by the wings. I have used, ever since July, 1874, a queen-catcher made of wire cloth, of which the Klinitz catcher is a very near imitation, and I have yet to hurt the first queen with them. I caught a queen last March with mine, when she got so cold she could hardly crawl in the cage, in going up the catcher, and I blowing warm smoke on her, too, all the while.

3—ABBOTT L. SWINSON, 44—65.

Goldsboro, N. C., Aug. 10, 1885.

QUEENS GETTING UNDER THE ALIGHTING-BOARD.

My success with bees is moderate. I have increased this season more than 100 per cent, and all my colonies seem to be in good condition. Some of the new swarms are giving more honey than some of the old ones. My bees are a common kind—neither Italians, nor yet the little black bee. I had one or two interesting experiences with swarms, in one of which a swarm came out two or three times and then went back. Suspecting something wrong I looked closely under the alighting-board and found a fine queen imprisoned in a spider's web, with a dozen or fifteen bees trying to release her. I released her for them and the next day got a fine swarm.

One day a fine swarm came out and was successfully hived; but I noticed on the table in front of the new hive two collections of bees. In one of these I found a dead queen, in another a queen just able to crawl about. A shower coming up I went indoors; and when I came back the second queen was dead, and the swarm gone—back, I think, to the hive from which they came. Could it be that, in fighting, both queens were mortally wounded?

EIGHT-FRAME HIVES.

I am still holding on to the Simplicity hive with wired frames, but can't, for the life of me, see the use of a bottom hive with ten frames. Putting in two broad frames with section boxes—one to right and one to left—shows that seven or eight frames are ample for brood. Why not, then, have the lower hive made for only seven or eight frames, instead of for these, and two broad frames for honey? It is certainly much more convenient to get honey from the second story than the first. Why not, then, force the bees to store all their surplus above, where it is much more accessible? I know that some think that bees store more at the sides than above; but my very limited experience is the other way. I know, too, the oft-iterated argument about the vast number of Simplicity hives in use. But that is not a valid argument, if a hive with fewer frames would do better. Some of my bees do so much better than others, I think I shall guillotine some of my queens as soon as I believe I can successfully introduce others. But, by the way, is it not troublesome to introduce queens while there is a second story on? I suppose a frame has to be lifted out of its place in order to watch the deportment of the bees to her, else she disappears from view between two frames.

One criticism—on you and some of your correspondents—about the use of words. Starch, for instance, is sometimes recommended, as, for instance, in putting in fdn. Is it the dry article, or the prepared that is meant?

J. A. GOREE, 8—18.

Tuscaloosa, Ala., Aug. 13, 1885.

Friend G., it was because of so many mishaps in the way of queens getting under the bottom-boards, etc., that I decided that our bottom-boards must be cleated clear round, so that there should be no space for queens, spiders, or toads, to get under the bottom-board; and I therefore concluded to make the bottom and cover of the Simplicity hive exactly alike. Where there is a hole under the hive, a new swarm is almost sure to make a mistake and crawl *under* the hive instead of *into* it. I have never heard of both queens being injured during a combat between the two queens. If your hive holds only seven or eight frames, and you should want to use it for a winter hive, you could not have chaff division-boards at each outside, and still have combs enough to winter the bees on. If you think the number of Simplicity hives already in use is not a valid argument, suppose you try a few eight-frame hives in your own apiary, and see how long it will be before you conclude it does make a difference, where you have to work them interchangeably with others. I do not believe that a hive with fewer frames will do better.—Yes, it is somewhat troublesome to introduce a queen to a hive that has an upper story on. Upper stories, however, I believe, are now considered to be the lesser of the evils attendant on having the whole number of combs spread out horizontally.—I do not think your criticism about the use of words well taken. If you look at the word "starch" in Webster, you will find two different references. One is the dry article, and another is the verb signifying the act of applying the starch. There is no name that I know of for the starch in a semi-liquid form, as it is prepared in laundries; and, of course, this is what we refer to when we mention using it as a lubricant.

SOUR HONEY, AND WHAT TO DO WITH IT.

I see in Aug. 1st GLEANINGS, page 531, that G. E. Hughes asks what to do with sour honey. As there are others who may have sour honey, and do not know what to do with it, I will give you the plan I used last year. I took a wash-kettle, filled it about three-fourths full of honey, put this in a large pot of water, put fire under, and boiled the water. As long as any scum rises to top of honey, skim it off and put in a vessel to cool; keep the scum, and you will get some honey at bottom. You can keep honey this way any length of time, and do what you please with it. Now, who will give us a cheap way to filter honey—I. e., to make dark honey clear?

New Orleans, La., Aug. 4, 1885. D. M'KENZIE.

It occurred to me, friend M., to suggest scalding the honey to remove the sourness, as the women-folks do with syrups, preserves, etc.; but scalding, so far as my experience goes, is so apt to give the honey a sort of cooked taste that I thought I would about as soon have it sour as to have it scalded.

HONEY "TURNING TO SUGAR."

It is an old saying, that "misery loves company." That is why I have felt less *lonesome* since reading friend Gordon's report in Aug. 1st GLEANINGS. With us, however, it is not alone the white-sumac honey that has turned to sugar, but all the honey made this season from maple bloom till the present

time. In a nucleus hive I found two pieces of combs as large as my hand, and these were partly filled with candied honey. These combs were built within a week, so our latest honey is as bad as the earliest. We have had a very dry season till lately, and I did think that accounted for the sugar; but for the past three weeks we have had abundance of rain; still the sugar nuisance continues. I attempted to extract some of the honey, but gave up the job in disgust. By revolving the combs at a very high speed I could get about 10 lbs. from a story containing 40 lbs. of honey. It was very dark honey while the sugar remaining in the cells was almost as white as granulated sugar. I think the bees have concluded the sugar business is a fraud, for they are carrying out the sugar and dumping it in front of the hives.

W. E. SKINNER.

Warrenton, Va., Aug. 17, 1885.

No doubt your candied honey looks like sugar, friend S.; and after you have thrown out the liquid portion by means of the extractor you have something very much like loaf sugar, which is made in the same way, by draining, or throwing out by centrifugal force, the liquid portion; but it is not sugar, strictly, after all; or, at least, not what we understand by the term sugar. All solid sugar taken out of honey is *grape* sugar, not cane, if I am not mistaken.

TURNING THE TABLES.

I take GLEANINGS and the *American Bee Journal*. With your perforated zinc to put between brood-chamber and top hive I can raise bees and honey by the mile, without any winter fixings; but with all these advantages you can put me in Blasted Hopes. I see honey is very low, and still falling—no sale, no difference how attractive it may be. I see a great howl put up against adulterating honey with syrup. I see no way to sell our honey but to adulterate the common syrup with it. That would be turning the tables "clean over." No use sending you a report. I have honey enough—more than I can sell.

Columbia, Tex., Aug. 14, 1885.

J. W. PARK.

Well, friend P., your remedy is a novel one indeed—producing honey so cheaply that, instead of adulterating honey with sugar, unprincipled venders will go to adulterating syrup with honey. Wouldn't that be a novel undertaking? And now who knows but our troubles may end in this way? I presume there is more than one article in their line where nice honey is cheaper than some grades of syrup.

THE PROGENY OF A CARNIOLAN QUEEN CROSSED WITH AN ITALIAN DRONE.

I have a Carniolan queen that came from Geo. H. Knickerbocker, of New York. She was mated with a yellow drone, and has so far given good results,—considering the season, which has been a poor one—there being no white-clover honey. The bees work early and late; and when it rains, if not too hard. They have made the whitest combs and the best-looking honey, and a good deal more of it, than the average of bees. They are very hardy, and as gentle as Italians. The old saying is, that "one swallow does not make a summer," but I shall have enough next year to give them a better test.

There is one point of which I wish to speak; and that is, they stick to the boxes better in cold nights, and I consider that one of the best. After taking

off the early honey they went right into the new sections and went to drawing out the fdn., even before there was any honey to put into them. They are now working on buckwheat, which is looking well. Basswood was never better, but we haven't enough of it, the most being cut off and sold to make Crandall's toys, and there are about 250 colonies of bees in this range.

I have bees in three different places, besides my home yard. I find that they do much better where there are only a few bees in a place. I can get more honey in my house apiary than I can in chaff hives.

C. J. HAIGHT.

Rush, Pa., Aug. 10, 1885.

ABOUT THAT AUTOMATIC HONEY-EXTRACTOR.

Charles West, on page 535 of GLEANINGS, wants some "late information about the practicability of the Stanley automatic extractor." I purchased a four-frame machine of that make last spring; have extracted about 400 lbs., and can say that it is practically reversible. The working parts are strong, well put together, and it looks as if it ought to last a long time. It is certainly a great saving of time and labor to be able to reverse the combs almost instantaneously, instead of lifting out one at a time and putting them back to get the honey out of the other side. While I am delighted with the working parts, I am not so well pleased with the can. It is made of good material, and well put together, but it has a flat bottom and no honey-gate, but a tin tube instead, and I do not consider any extractor complete that will always have two or three gallons of honey standing in it unless you tip it to one side so it can get out. Bro. Stanley, in the cut of his extractor, shows a honey-gate; but when he makes it he prefers a tin tube and cork. I do not find fault with Bro. Stanley for making his extractor with a tin tube instead of a honey-gate, but I was not a little disappointed to find *mine* that way; and I think when goods differ in any way from a cut that is intended to describe them, such differences ought to be made known by private letter or otherwise.

4—A. R. NISBET, 100—143.

Dobyville, Clark Co., Ark.

To be sure, friend S. ought to make some explanation, if he sends out a machine that does not agree with his illustration, and he certainly can afford a good honey-gate for the price he gets for them. As we never heard this complaint before, may be yours was finished in that way by mistake, and that the others are as they should be.

DOES CONTRACTING THE BROOD-NEST INCREASE THE TENDENCY TO SWARM?

Do not wide frames for sections, or the contracting of the brood-nest, in any way cause bees to swarm more than they otherwise would? If a swarm of bees has plenty of room all the season through, would they swarm at all? In introducing virgin queens as you describe in last issue of GLEANINGS, does it make any difference whether they come from the lamp nursery or the hatcher? I kept a lot of virgin queens caged up, four or five days, then tried to introduce them by the same plan by which I had successfully introduced a lot of fertilized ones. I lost about every one of them, proving true what you say in July 15 No., page 504. In Aug. 1 No. you want some plan for introducing a virgin queen, five to seven days old, to a colony queenless 24 hours. Where can they be

kept so that the bees will receive them? I believe, that if there is a plan found it will be by a cage that allows the bees to liberate the queen, the length of time for keeping her away from the bees being regulated by the thickness of candy or material they have to work through.

4—WM. FULLER, 19—45.

Woodville, Wis.

Friend F., giving plenty of room in a hive will often be the means of inducing the bees to store honey and not swarm; yet the rule is by no means invariable, for swarms often come out when the hive is only half full. When a colony of bees get their sections full, however, and their owner neglects to give them more, they are pretty certain to get the swarming fever. Your success in introducing virgin queens four or five days old is just about what I should expect. They can by no means be introduced as easily as a fertile laying queen.

WHAT AILS THE BEES?

This spring I bought from a farmer two colonies of bees in old box hives. One of them sent out three large swarms, and all are doing well. The old hive is now in a bad condition. It smells badly, and they don't seem to be doing much. Is it foul brood? if so, is there any remedy? As you are good authority on bees, I would thank you to tell me what I had better do. If it is contagious, would it not be better to destroy them?

N. W. EDDY.

Toledo, O., Aug. 24, 1885.

Friend E., I hardly think it is foul brood, from your statement, although it may be. Your great trouble is, that your bees are in a box hive, and the only thing for you to do is to break or cut out a comb containing brood, so that you can make an examination. If you find the combs really contain dead brood, and when the cells are punctured with a little stick or the point of a knife, you find this brood in a pasty condition, emitting a bad smell, you may be certain it is foul brood. Another symptom of foul brood is, that after the caps of the cells have sunken in, a small hole like a pin-hole is seen in the center of each cap.

HONEY-DEW AGAIN, BUT ONLY A SLIGHT TRACE.

I notice in the editorials of July 15, that you have heard no report from honey-dew this year. We have had some here, but not nearly as much as last year. There is just enough to give the honey a pollen, or breadly taste. I find it helps such honey greatly to heat it a little. How long will it take uncapped honey in the hive to ripen? The honey crop is a failure, compared with last year; bee-keepers will not get half a crop around here.

Hartland, Wis., Aug. 6, 1885. E. M. CROUCH.

SOME QUESTIONS FROM FRIEND BAUM.

I examined a nucleus that died of dysentery, and found some white substance on and in the comb, and, to my astonishment, I found it was table-salt crystals. Now the question is, Where did they get it, and what did they want of it?

Will the queen voluntarily leave the old hive in swarming time, or is she compelled to do so by the workers?

Bees are doing pretty well yet. They are still dropping in the forenoon. The honey and pollen come from corn-fields and part from red clover. The grasshoppers are destroying much red clover.

I have very nice white-clover honey, and it is selling fast at 15 cts. per lb. Last year I sold at 20 cts.; but this year a bee-man shipped to this part at reduced rates in the beginning of this season. I sold for 18 cts. per lb. till I had to sell lower; extracted, 12½ cts. per lb.

I love to read GLEANINGS and all it contains. May God, the giver of all good, guide and direct us all to that which is right and good, and ever on the side of righteousness!

A. H. BAUM.

Ashtland, Ohio.

Friend B., it hardly seems possible that the bees carry in enough salt water so that it crystalizes on the combs, as you mention. Was not some brine by some accident spilled on these combs?—I think the queen voluntarily leaves the old hive in swarming time, for I have seen them come out several times among the workers, but oftentimes only toward the last.

MORE ABOUT HONEY POISONING—A NEGATIVE VIEW OF THE MATTER.

I have just read the "Honey-Poisoning Case" on page 521 of GLEANINGS; and in response to your question, "Can any of our medical friends suggest what the poison probably was, from the nature of the symptoms given?" I take the liberty to say this: Gelsemium, or yellow jessamine, bears, generally in profusion, a bright-yellow flower, funnel form, an inch to an inch and a half in length, and very fragrant. The flowers appear in March and April. I am a student of homeopathy, and know something of the effects of the drug here under consideration. We give gelsemium quite frequently for intermittent fever, sudden and severe muscular effects from taking cold, etc.; and though we often give the strongest tincture, in one and two drop doses, at intervals of from 15 minutes to an hour or more, we never fear any poisonous effect. The most prominent symptoms of an overdose is a peculiar effect on the optic nerve, producing double vision; but aside from a slight disturbance of the circulation, I have never noticed any ill effect of what homeopathic physicians call an overdose. I can not believe that gelsemium in the honey caused the poisoning, because the symptoms do not indicate it; and because not enough could have been taken in that way to cause death. This, you see, is a negative answer to your question. Perhaps some one else can give the positive. The two together will cover the whole case.

J. D. GEHRING.

Park College, Mo., Aug. 15, 1885.

A REPORT OF THE STANLEY AUTOMATIC HONEY-EXTRACTOR.

I have had extremely good success this season with my bees. It is the first season I ever extracted, and I always thought that I never would extract any honey, for I have seen others work their machine, and there was so much daubing around, lifting the combs out to turn them, that it sickened me of the extracting business. But when I saw the Stanley Automatic honey-extractor, then I made up my mind it was the machine for business, so I bought a three-frame machine, and found it to be just what it was represented, and I would not take any other machine as a gift, if I had to pay \$50.00 for one of the Stanley machines. I have extracted wired combs, and those that were not wired, and have not broken a single comb. My combs are 12 inches square, and would be more liable to break than the

Langstroth. If I were to buy another machine I would get a four-frame instead of a three-frame, as I could get along so much faster. It would take no more turning to get the honey out of four frames at once than three, and but a slight difference in the price of machines. My advice to all would be to buy a four-frame machine. I have always run my bees for comb honey; but if I can get 8c per lb. for extracted at home, I shall not use any more sections.

F. F. CROCKER.

East Randolph, N. Y., Aug. 12, 1885.

YOUR FOOT-NOTES TO CORRESPONDENCE.

I like them. Your young readers would soon be led into devious and mysterious caverns, and probably be lost in the great "Mammoth Cave" of our chosen and beloved science, without our trusted knight of the lantern, whose years of experience and honest walk and pleasant ways have guided us so happily and safely on. Whenever you give up the lantern to one of the new explorers, even though he has gone a little way safely, we shall all feel uneasy, and wish to procure a guide that will lead. I know of no publication more completely edited than is GLEANINGS. And, too, its smooth paper, convenient size, clear print, appropriate headings, full addresses of correspondents, and a dozen other admirable features, make it a marvel of excellence. It is to be hoped our friends will subside in their suggestions.

J. L. CALDWELL.

Mart, Texas.

A WISCONSIN REPORT.

This has been a poor honey year so far; a late and cold spring; white clover yielded very little. Basswood, of which there is a great abundance, did not bloom as full as usual, and the very warm weather and plentiful rains ripened it too soon. It lasted only five or six days. Several men in this county who have large apiaries tell me they have taken no surplus, and do not expect any. One of these parties took 15,000 lbs. last season. I am doing better, as I have not so many bees (ten colonies, spring count). One of my first swarms has given me 70 lbs. of very fine comb honey in 1-lb. sections. I may get 500 lbs. all together. There is a number of honey-plants here that the bees do not work on. The Simpson honey-plant grows profusely in the wood-pasture adjoining my apiary, but I have not seen a honey-bee on it, and I have been watching closely. The yellow-jackets work on it from morning until night. Do you think they drive the bees away, or what is the trouble? There is plenty of the common thistle, also, and the bumble-bees and other insects work on it; but the honey-bees do not notice it. They are working now on early buckwheat and the asters. I will send a full report later.

HARRY LATHROP.

Browntown, Green Co., Wis., Aug. 12, 1885.

Friend L., the reason why the bees do not work on the Simpson and other plants you mention, is because they are getting plenty of honey, more to their fancy, elsewhere. Some time ago we had a communication from a friend who had a patch of figwort, but not a bee could be found, although it was laden with blossoms, and their little cups were full of nectar. One morning, however, he was astonished to see the whole piece in a perfect roar, and literally alive with bees. The other pastures had failed, and they had just discovered the figwort.

LOCATION OF AN APIARY IN A VALLEY, NOT DESIRABLE; A GOOD YIELD FROM BASSWOOD.

In your A B C book, on p. 11, you say you would have the apiary located in a valley rather than on a hill. Your reasons for the same are no doubt good. I live on the West Fork of the Monongahela River, a pretty large stream, and in the summer time there are a great many heavy fogs, lasting at times until ten o'clock in the day. I have thought that the fog was injurious to bees, as they seem to do better on the river hills than along the river bottoms. I am just a beginner, and wish to locate permanently soon. I should like to hear from the brethren who have had a chance to know in regard to the above. GLEANINGS is a very welcome visitor to me indeed. There is no white clover here this summer, but the best yield of basswood for years, lasting about seventeen days. Bees are now working strong on buckwheat in the for part of the day. They swarmed but little here this season.

L. H. ROBEY.

Worthington, W. Va., Aug. 12, 1885.

MANILLA ROOFING-PAPER FOR PERFORATED DRONE-EXCLUDERS.

I send you a piece of Fay's manilla roofing. Won't it do for honey-boards and drone-excluders, perforated like your zinc? Would the bees cut it away? How would it do enameled, after being perforated? I notice in GLEANINGS that wooden boards are used; but the bees fill the holes. What would the difference in cost be, between zinc and the manilla? J. W. PARK.

Columbia, Tex.

Friend P., the sample of paper you send is very nice, and it seems as though it might answer the purpose, although I should be afraid the bees might in time cut or bite away the holes so as to make them a little larger; then you would have the queen getting up, without being able to find her way back again, as friend Fowls mentions on page 592. I am afraid, too, we shall have the same difficulty with the perforated wood before we get through with it.

A CAUTION IN THE USE OF PARIS GREEN.

Having read the articles on poisonous honey, and your comments on the same, I conclude your theory in regard to the poisoning is quite possible. This morning I had occasion to put Paris green on some late potatoes that have got somewhat weedy, and I noticed that the honey-bees were at work on several varieties of the weeds, and I was careful to pull all such up where I put the green. The weeds I noticed them working on were heart's-ease, a plant much resembling smart-weed, and black plantain, or buck-horn. I have seen the bees in large numbers on chick-weed in the forenoon. This is a common weed in many localities, and grows under potato-vines and all sorts of vegetables. It would be an easy matter for the blows to get severely poisoned by the poison being carried down by heavy dews and rains.

RASPBERRIES AS A HONEY-PLANT.

We grow all sorts of raspberries, and during their blooming they are literally covered with honey-bees. I send you a box to-day containing a cutting of Conover's Colossal raspberry, to show you what it looks like when in bearing. The sample is from a plant that was set last spring. I bought eight plants a year ago last spring, and buried the tips,

from which I got nearly 200 good strong plants, and we picked 21 quarts of mammoth berries from the eight hills. I can furnish you a few plants next spring if you will jog my memory by a postal about that time. Of all the black caps I ever grew, I have tried about every variety offered; and the Gregg takes the lead, unless you choose to call the C. Colossal a black cap. P. SUTTON.

Exeter, Pa., Aug. 11, 1885.

Thank you, friend S., for the specimen of the Colossal raspberry; but the fruit had all spoiled just before it reached us. I should be very glad indeed to get some plants, either this fall or next spring, if you will be kind enough to furnish us some. Raspberries and buckwheat we can go into safely, for furnishing bee-pasturage; and if the honey doesn't pay, the fruit and grain will. By the way, I want a little book written on buckwheat, and another on the culture of raspberries. I want them about the size of our potato-book, and I want the work done as thoroughly as Mr. Terry has done it in regard to potatoes. Where is the man who has made either buckwheat or raspberries his hobby for a sufficient term of years so he can give us an exhaustive treatise, taking in all the points, and bringing them clear up to the latest methods of the present day? Now, friends, please don't write such a book, any one of you, until I have first had some correspondence with you. We want a man who has raised these crops by the acre, and who has made money from them.

DIVIDING COLONIES.

If the bees will swarm in season, we let them do so; if not, we divide. For this, many plans have been given; nearly all say, "Hunt up the queen, leave her with a few bees and a few combs on the old stand; set the new hive at a distance, having in it the largest portion of the bees, combs, etc." Now, we want to say we have tried this plan, and it has never proved satisfactory. In the first place, the colony on the old stand gets nearly all the bees, leaving the other very weak. In the next place we can seldom find the queen in a black or hybrid swarm when the swarm is very large. Our plan is to place a new hive by the side of the old one, and then, with smoker in hand, give each one half the bees and half the old combs and brood; fill up each with frames of foundation; spend no time in looking for the queen; let her go where she pleases. Now set the old hive a foot or two on one side the old stand, and leave the new one about the same distance on the other side. Make them look as near alike as possible. If you next day discover most of the bees are going into either part, move that one a little further from the old stand. In this way we can *always* get them nearly equal.

Now about the queen. The hive that has none will soon show it by their actions—running about. Now, if you have a good laying queen, all the better, if not, give a queen-cell; if neither, they will soon raise a queen of their own. The work is now done. We would rather have either one of these for wintering than any young swarm, for each has one-half old combs. These should be placed in the center of the hive for winter use. Of course, hives must not stand too close together, to carry out this plan. We generally divide, in this section of buck-

wheat, about the last of July or first of August, but the plan will work any time in the summer.

Cochran, Pa., Aug. 24, 1885. N. N. SHEPARD.

The above directions from friend Shepard, who gave us the swarming-box, I should approve in every respect; only if the division is to be made as far north as we are, as late as it is now, I would by all means have a laying queen for the queenless division; and, in fact, I think it would pay to have a laying queen at any time where a strong colony is divided.

HILLSIDE APIARY; THE LATTER PART OF THE SEASON A LITTLE MORE FAVORABLE.

I have named my apiary the "Hillside Apiary," and have the hives arranged somewhat after one of the cuts in the A B C. I do not think that my hives will average over 25 lbs. apiece this year, as it was so very dry during the white-clover season; but we have had lots of rain here for the past two weeks, and the flowers are coming out nicely now, and I see the bees are working very fast in the boxes. Two or three hybrid swarms in particular are doing a brisk trade just now, and it may be I shall get my 50 lbs. of comb honey from a hive yet. I hope the warm weather may continue for awhile this month and the next. I might make a good crop, the way clover seems to be blossoming now.

WILMER J. MOORE.

West Grove, Pa., Aug. 24, 1885.

CLIPPING QUEENS' WINGS.

I want to tell Ole Foggy (GLEANINGS, Aug. 15), that I want one wing cut off from every laying queen in my own apiary. Why? Because after 5 years' experience with clipped queens, I am fully convinced that I can manage bees at swarming time with more ease and less loss of queens and bees than I can in any other way. I have increased my apiary from two colonies in 1880 to 57 colonies at present date; and to count what I have sold and what have died in winter, I have probably hived 100 swarms with queens having clipped wings, and I can say truthfully that I have lost only one queen in any way at swarming time, and have never had a swarm to run off and leave me. My bees never supersede their queens until they are ripe with old age, and are on the decline. My neighbors say that they lose one swarm out of every ten by their going off to the timber. I can not see why Doolittle's bees and my bees and many others' behave so well with clipped queens, while A. I. Root's, Heddon's, and many others' behave so badly that they condemn the plan.

J. R. NICHOLS.

Danville, Ind., Aug. 25, 1885.

AN APICULTURAL DISPLAY AT THE CHILLICOTHE FAIR.

Friday last closed our county fair. The fair was a success. For the first time in the history of the fair there was a display in the line of apiculture. C. M. Roberts had Root's foundation-machine, some foundation drawn out by bees, some extracted and comb honey, and a very handsome large can for extracted honey. E. Magenhoffen, an extractor; D. Brown, an observatory hive of Holy-Land bees and some queens of the same race. I had an observatory hive, with one frame of bees and brood of the native black bee, the style of hive I use, with its fixtures, a queen-nursery after Alley, a fertilizing hive, and a few other things in the bee line. There was a very pleasant interest manifested in our dis-

play, and propose to improve on it very much next year.

FRANCIS W. BLACKFORD.

Chillicothe, Ross Co., O., Aug. 24, 1885.

PACKING FOR AIR SPACE OF HIVES.

Our English friend Cheshire, who has made so many able contributions to scientific bee culture, suggests cork waste as the best material for this purpose. Where it can be readily procured, nothing can be better. I will name something which in this country can always be got—dry corn-cobs, ground say as fine as tan-bark. The great non-conducting power of corn-cobs is well known; and ground as I suggest, cobs would be very nearly as good as cork.

L. L. LANGSTROTH.

Oxford, Ohio.

Friend L., at the Toronto convention this subject of cork for packing was discussed quite a little. The difficulty of obtaining it in many localities is the principal objection to its use, so far as I know.

WHY DO THE BEES THROW OUT CAPPED BROOD?

What makes young swarms of bees cut out their young bees just as they are going to hatch? I have had three after-swarms do this.

J. G. MEEKS.

Barnhill, Ill., Aug. 24, 1885.

Friend M., it is my opinion that they do it because your combs are infested with moth worms. Were not the combs exposed to the moth miller before you hived your young swarms on them? If I am right, it would do no particular harm, especially if your bees are Italians, for they will very soon have the combs all cleared from these pests.

COLONIES THAT WON'T START QUEEN-CELLS.

I have had trouble to get my bees to build queen-cells, some colonies refusing to altogether, and others building very poor ones. My neighbor, Mr. J. T. Wilson, has the same trouble. Why is it so?

Nicholasville, Ky., Aug. 10, 1885. J. W. SHEBY.

I should say that such colonies had a queen of some sort, or a fertile worker—see the A B C book. If you want a great many large strong queen-cells, you want to use a colony of bees that have some Holy-Land blood in thier composition.

SWARMS GOING OFF WITHOUT CLUSTERING.

I feel like writing a few words in reply to Ole Foggy, concerning the matter about bees always settling or clustering when they issue naturally from the hive. He says, "They never, never, never go off without first settling." Now, friend Foggy, I have had two swarms of that kind myself. I was on hand when they began to issue from the hive, waiting patiently for them to cluster; but the time was short, for they soon began to move off, and I followed; but when they came to the timber they arose over the trees and left me below, and I retraced my steps, feeling badly over my loss, for they were first-class swarms. One year ago this season a neighbor of mine had a swarm come off on Sabbath afternoon, but they did not look for a place to cluster, but started for the woods.

My father got his start of bees from a swarm of this kind. A neighbor had a swarm issue, and left without clustering. He followed them about three-fourths of a mile and treed them, and told my father he could have them. But I will agree with Foggy,

that it is all nonsense to thump the bottoms out of tin pans and pails, and to shoot, for the sake of making a great noise to deafen the bees so they can not hear the "king," as such people term the queen.

E. SALISBURY.

Ossian, Ind., Aug. 25, 1885.

LETTER FROM GEORGIA.

HOLY-LAND BEES; HONEY-PLANTS; PERFORATED ZINC; MONEY CROP.

BRO. ROOT:—I have thoroughly tested the Mt. Lebanon strain of Syrian, or Holy-Land bees, and I must say that I believe they are the bee for the South. I regard them as superior to the Italians in several respects. 1. They multiply more rapidly, and swarm less. Their colonies are full to overflowing all the time. The Italians here are always swarming during the swarming season. I have known the Holy-Lands to swarm but once.

2. They never disturb any one unless they are first disturbed, while a stray Italian is constantly stinging somebody, especially when they have a supply of honey on hand. For several years I kept my Italian apiary near my dwelling; but they were constantly stinging the cook, and putting members of the family to flight generally. I was compelled, through self-defense, to change these to Holy-Lands, and the trouble was over. The Holy-Lands attend to their own business.

3. They don't dwindle away in the spring, like the Italians, but are always strong, healthy, and industrious. There is but one objection to the bee. They require more careful handling than the best strains of Italians. In this respect, however, they differ but little from what we call dark Italians. A veil should be used in manipulating them.

I still keep the Italians in a separate apiary one and a half miles distant, and they are doing well. My choice queen gives me considerably over a hundred pounds of comb honey, and made the most of the comb at that. She is very large, beautiful, yellow, and her progeny well marked. I am just starting an apiary of the albino bees at another one of my farms, and hope by the end of another year to be able to report further.

HONEY-PLANTS.

The mimosa and all its species is a fine honey-plant here. I have seen the bees swarm upon its wide-extended boughs all day long, attended by troupes of hummingbirds and other honey-gatherers. You know the sensitive plant belongs to this species. It is also much frequented by the bees. The flowering pear is a great favorite with our little friends; and as it blooms early it is very valuable. The virgin's bower, and goldenrod, are now in bloom, and also King Cotton, from which the bees derive much honey. Our best bee-plants are elm, black gum, poplar, persimmon, goldenrod, horsemint, the clovers, clematis, white elder, cotton, and sourwood, with which our country abounds. Think of that, and add to it the fact that a two-frame nucleus can be wintered on the summer stand, without any protection, and tell us why we may not do well at bee culture in Georgia.

PERFORATED ZINC.

Italians and Holy-Lands all work well through perforated zinc plates (old style). Where it is not used, the queen will invade the surplus department.

Griffin, Ga., Aug. 25, 1885. W. E. H. SEARCY.

REPORTS DISCOURAGING.

REPORTS from different quarters are what we want, either good or bad results. In this vicinity our report so far is not very flattering. Our bees wintered badly—cause, neglect.

This spring was very backward. The bees did not gather much from early flowers, rarely enough for brood-rearing. White clover came in bloom June 1, and for a few days bees gathered honey very fast; then wet weather set in as last year, which made white clover a failure. At present the bees are doing something; and I think, as we have had fine rains the last few days, the fall will be a good one. Sometimes the fall season is splendid. Buckbush is just in bloom. Smartweed, Spanish needle, and goldenrod, are to come.

Clarksburg, Mo., July 27, 1885. C. H. MCFADDIN.

The honey crop for 1885 in Pennsylvania will not be more than one-tenth the average. This is much less than I reported a month since, but it is certainly the truth. I see California and other sections also report failure. It would, therefore, be advisable to expect better prices than for many years.

S. W. MORRISON.

Oxford, Pa., July 26, 1885.

A LETTER FROM F. W. BURGESS.

He Gives Us the Benefit of His Experience on Several Matters.

REVERSIBLE FRAMES.

MY experience with reversible frames convinces me that there are advantages besides having the combs built to the bottom-bar; but I doubt if it pays, and I doubt if they ever come into general use. I find, with 80 colonies and my office work, I have no time to manipulate frames, but, like Heddon, feel the necessity of working hives rather than frames.

CARNIOLAN BEES.

On account of their color I gave them no favor. They seemed very gentle, and are probably good in other respects, but they will certainly make hybrids resembling a mixture of our common blacks. I want none.

PERFORATED ZINC.

It usually keeps the queen in the lower story, and makes it easier to remove frames for extracting. I should never use it for box honey. I like it for extracting.

MAKING NUCLEI.

Doolittle's plan is first rate; but as I have made mistakes I will tell them. I lost one queen while giving a comb that had eggs and brood in it. I lost another by carelessly giving one with the bees, and I lost the third by making a nucleus from a hive that was queenless, and contained fertile (?) workers, and it is this which might be repeated by others.

INTRODUCING VIRGIN QUEENS.

On page 522 of GLEANINGS, Doolittle says he can take bees from three nuclei, and shake one-third of each into a cage, and thus make three cages of mixed bees which will accept a virgin queen; but when he puts them back into their hives, five out of six will be killed by bees returning from the field, etc. I would say, put them on a new stand, far enough removed to avoid the returning bees.

MAKING WAX.

I melt in a tin kettle half full of water (iron colors

the wax). When it boils I dip and strain through two folds of mosquito netting spread over a coal-sieve, into a large honey-can the size of an extractor, it being half full of water. Empty the strainer as often as the dirt clogs the wax. Keep every thing hot, and there will be no waste. The wax is easily removed from the can when *thoroughly cold*, and does not adhere to the sides at all. From the bottom of the cake I scrape off the dirt, melt and pour again, when the wax is as beautiful as Mr. Dant's. The last cake I made was 18 inches in diameter, and 8 thick. The above mode is not dauby nor wasteful. I give it in answer to your foot-notes on page 550, August GLEANINGS, for fear you may mislead. I, too, have discarded a wax-extractor.

Huntington, L. I., Aug., 1885. F. W. BURGESS.

In regard to introducing virgin queens, friend B., the objection would be that we should have to make new colonies all the while, and this would generally be an objection, it seems to me. Friend Doolittle contemplated introducing virgin queens to such colonies as were queenless, or to nuclei already established. I have for years been well aware that we could introduce queens easily at the time we formed a new nucleus. In your plan of rendering wax, friend B., it seems to me there must necessarily be considerable good wax adhering to the refuse contained in the mosquito netting.

MRS. CHADDOCK TELLS HER EXPERIENCE IN HONEY-GETTING.

A GOOD WORD FOR OUR OLD HONEY QUEEN, AND SOMETHING ABOUT NOT WORRYING, ETC.

THREE years ago you told in GLEANINGS about a colony of bees that you had, that gathered so much honey that you called her your "honey queen," and you raised queens from her and said if any one wanted to try them, to say "Honey queen" when ordering. As that was just the kind of queen that I had always been wanting, I sent for one immediately. The answer came back that the "honey queens" were all gone; but afterward, when I sent for queens, you sent me one of them. It was the 5th of July when she came, and too late for the white-clover honey; and as the next two seasons were no honey years, I could not tell any thing about her. I always kept track of her, however, and this year she gave 100 lbs. of honey, while the most that I took from any other hive was from 36 to 40 lbs.

This has been a splendid year for bees, and a pretty good year for honey—not one of the best, but pretty good. This honey-queen colony was the strongest one I had last spring, and before swarming it was working in two sets of sections. When it swarmed I hived it (or, rather, let it hive itself) on a full set of empty combs, and transferred the partly filled sections from the old colony to the new one. Seven days later I put on another tier of sections. When the white-clover honey crop was gathered I took off the three boxes of honey—all of it bulged out and capped over. I sell honey in these boxes nearly every year, and I know they hold from 35 to 40 lbs., so that I am safe in saying that this honey queen gave me 100 lbs. of honey. Besides this, the old colony sent out an after-swarm, and they have some honey in the sections, and the old colony has

a box nearly full. But as I changed these about, just as it suited me, taking out and putting in brood, I can not tell what credit to give them, so I give them none at all. Next year (if this queen lives) I will put every thing down in black and white, and she shall have all the honor that is due her.

I want to thank all the friends who have been so kind as to write me letters of "condolence" about my beeswax experience. I am very sorry that sister Culp lost any sleep over me, and I feel very meek under the Scripture she quotes. But, does not same Bible say, "Be ye not troubled," and "take no thought for the morrow," "consider the lilies," etc.? Now, I think I am rather prone to gathering up the fragments, so much so that sometimes, when I have twenty things to do all at once, I envy any one who can sit calmly with folded hands, "considering the lilies," and I wish that I could do it too.

In the first flush of disappointment, when I thought I had ruined all that beeswax, I felt as I suppose a fellow does after he has spent all his nickels, for ice-cream for his girl, and then she suddenly deserts him for the "other fellow." He feels as if all flesh is grass, and vows he'll never be kind to any one again; but pretty soon some other girl smiles on him, and he goes to buying watermelons for her, and taking her to the fairs, and life is worth living after all. When the Dantons wrote me that my beeswax was spoiled, I supposed that I should not only have to lose it, but pay the express charges also. But afterward they wrote that there was enough good wax in it to pay the express charges, and for the foundation that they sent me (about two dollars' worth), so that I did not feel quite so desperate. The point with me is, that if I can not make money without worrying all the time, I won't make money at all. I think there is no one thing so bad for people, especially women-folks, as worrying. When I read what you said about not having the doctor for Huber's sprained wrist I wanted to say, "It is better, much better, to have the doctor, and let him rub on the arnica, even if it does not a particle of good, than to have the mother worrying all day and all night about it, thinking that he might be deformed for life." I tell you, no woman can afford to worry that long to save two dollars.

I like sister Culp; I like her "grip" and hang-on. I read about the way she "fattened" her bees on maple sugar, and I liked that very much. I feel sorry, too, for the lonely way she is called to walk in, and am glad that she has the grace and strength to walk in it bravely. MAHALA B. CHADDOCK.

Vermont, Ill., Aug. 20, 1885.

I am very glad, my good friend, to know that you are getting a good crop of honey, and that the honey queens, or red-clover queens, which I believe is what we called them, are still keeping up their reputation. I should say they are celebrated for their longevity as well as for the working qualities of their bees.—I like what you say about not worrying; but I do not understand it to mean that we can not push things, and make them boom; that is, one may be cheerful and full of peace, even if he does not sit down with hands folded. In regard to the doctors and arnica, by all means have them if it will make you feel easier, even if they do not do a particle of good in that particular case.

TOBACCO COLUMN.

A BOY 17 YEARS OLD STOPS ITS USE.

FIVE months ago I left off the bad habit of tobacco, after being its slave five years. Please send me your little book, "Dose of Truth."

HARRY L. DECKWORTH, age 17.
Greenwood, W. Va., May 28, 1885.

I have used tobacco for quite a while; but if you will send me one of your smokers I will try to stop; and if I can not, I will return the money.

North Adams, Mich.

L. KENRICK.

HOW THE "DOSE OF TRUTH" ACTS AS A REMEDY.

My friend has received the smoker you sent, and is very much pleased with it. The lecture on tobacco that you sent him, he has read, and he remarked to me this morning, that if he had not quit tobacco before, he should discontinue its use after reading that. Friend Root, you are doing a grand work; go on, and may the Lord bless you! J. F. TEMPLE.

Packerville, Ct., June 16, 1885.

I am in receipt of your catalogue, also GLEANINGS. After reading the latter I have concluded to abjure entirely the use of tobacco. Should I ever resume the use of it I will cheerfully remit the price of the smoker. I have just commenced in the bee business, and can not as yet tell how I am going to succeed; still I think I can see some money in it. In Eastern or Central Florida, I think bee-culture would be a paying business; here, however, on the Gulf Coast, with our variable weather, it is as yet only an experiment. JOHN H. RAUCH.

Warrington, Fla., June 19, 1885.

I have just completely thrown tobacco aside; and if you are still in the habit of sending your subscribers a smoker when they quit the use of it, I should be very proud of your present — not that I quit the use of it for the pitiful sum of a smoker, but I saw that it was of no benefit to me, only an expensive, filthy, indecent, dangerous habit, liable to burn up everything I had. I would thoughtlessly go into a corn-crib, or anywhere else, with pipe lighted, and so I came to the conclusion that a man could not be a safe gentleman and use the filthy stuff. If you see proper to send me the smoker, and I ever resume the use of tobacco in any way, I will pay you twice its value. J. W. SEGLER.

Paris, Tex., July 6, 1885.

A GOOD YIELD OF HONEY, AND SOMETHING THAT IS A GOOD DEAL BETTER STILL.

I send you a sample of my "Northern Michigan" honey. How does it compare with the honey of your State? The honey season is over, and we have had a splendid yield. I have taken 100 lbs. from some swarms, and they have plenty for winter. I shall winter my bees on natural stores. Well, Bro. Root, I have quit the use of tobacco, with the Lord's help. I have been a smoker for 18 years. I threw the pipe and tobacco away four months ago. I have had no wish to take it up again. The Lord being my helper, I never shall. I feel a great deal better. I can go to bed and sleep soundly all night, and get up in the morning feeling a great deal better every way. I believe that tobacco comes pretty near being a twin brother of whisky. Thank God, I never drank whisky.

J. REED.

Orono, Mich., Aug. 19, 1885.

Many thanks to you, my good friend R., for the nice sample of comb and liquid honey you send. It compares favorably with the best we have seen this season, or any other season, for that matter.—May God bless and strengthen you in your determination to abstain from tobacco evermore! I suppose you wrote and told me about it, simply because you know that it will make me feel happy, and I thank you for the compliment you pay me there. It is true, you do not say any thing about having a smoker, but I shall enjoy the privilege of sending you one all the same, and you can keep it as a reminder of your resolution.

KIND WORDS FROM OUR CUSTOMERS.

The A B C book and queen came to hand all right. Many thanks, I am just beginning bee-keeping, and your book is invaluable. I think the queen began laying in less than five minutes after she was released.

FRED TERISS.

Union Center, N. Y., July 6, 1885.

Please find inclosed 50 cents for GLEANINGS. It is always welcome in our home, for we love to read Our Homes. I think it ought to be in every family in the land.

So let our lips and lives express
The holy gospel we profess;
So let our words and virtues shine,
To prove the doctrine all divine.

Stone Creek, O.

HENRY PAULS.

HOW THE CHILDREN TAKE TO THE CARPET-SWEEPER.

The children put the handle in the sweeper as soon as we got home, and went to work. They took up all the dirt they could find, and then tore up pieces of paper and threw them on the floor to get it to take them up. In the afternoon Harry came to me and asked if he could not tear up some paper, and throw it around; he said he wanted to see the carpet-sweeper "eat it."

M. B. CHADDOCK.

Vermont, Ill., Aug. 20, 1885.

KIND WORDS FROM A NEW HAND AT THE BUSINESS.

I am one of those awkward, good-for-nothing bee-masters that I have just had the pleasure of reading about in your A B C book; or, rather, I am one of those green fellows who have just taken hold of a small lot of bees, thinking perhaps they might make enough for themselves, and enough to spare me to keep soul and body together. And I am a little afraid that I haven't got quite as much energy as I might have; however, as necessity knows no law I shall try to "take the bull by the horns" and see if I can make friends with the dear little creatures, and get them to divide profits with me. Well, enough of this. I purchased, a few weeks ago, one of your A B C books, and I assure you that I never read a book with so much pleasure; every bee-man should feel under everlasting obligations to you.

P. A. WEST.

Milledgeville, Ga.

SOMETHING ABOUT OUR EXTRACTORS AND FOUNDATION-MILLS.

I've tried the "wash-machine," as the people called it at Hopkins Station. Every one, nearly, wanted to know what it was for, and how it worked. I told them what it was designed for, and now I can tell them how it works. I never saw a fdn. mill myself before, so you see I had the first one to work with I ever put eyes on, and have had good luck in trying its work. I have never had better fdn. than I have now—no one to show me the first principle. I will inclose sample of my work. I have made about 25 lbs., all like this sample. Does it not look well for the "first flap of the boot"? I made narrow dipping-plates, which I think work finely, made of hard pine lumber. I never found the directions for putting the two pinions together right until my eyes happened to spy it on the outside of an envelope, tacked to the board that goes under the rolls. I thought it to be my address, but it's all right now. The tank is fine for the money it cost me.

Wayland, Mich., May 26, 1885. GEO. TISHHOUSE.

Since I last wrote to you I have tried the foundation-machine, and it works well. I can turn out foundation with higher side-walls than any I have seen here; and several other bee-keepers about here have remarked the same thing.

Hastings, Hawks Bay, N. Z. JAMES ADAMSON.

My Novice extractor arrived O. K. from your factory, and works like a top. Every thing I get from you always gives me pleasure. Said one of my bee-friends the other day, "A. I. Root is a good man; what you get from him will be all right." "Amen!" said I, and so it is, my friends. W. E. H. SEARCY.

Griffin, Ga., Aug. 24, 1885.

THE BLISS TELEPHONE.

I received the telephone all right, and it is a little "daisy." It works better than one here which cost \$16.50. I think I can sell quite a good many of them here. There are ever so many who tried mine, and like it so well, they say they must have one. JAS. R. WHEELER.

Waterford, Pa.

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

A. I. ROOT,

EDITOR AND PUBLISHER,

MEDINA, O.

TERMS: \$1.00 PER YEAR, POSTPAID.

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, SEPT. 1, 1885.

The Lord is my light and my salvation; whom shall I fear? the Lord is the strength of my life; of whom shall I be afraid? — PSALM 27: 1.

THE BEST GIFTS.

THOSE God gives us *every day*, and which we shall forget to be thankful for if we don't look out.

PRICES OF SUGAR AND HONEY.

THERE has been a recent advance on sugar, of about a cent a pound, which will probably help the prices on honey as much as that, or more.

THE SIZE OF OUR FAMILY AT THIS TIME.

It looks some as if we should not get up to 7000 again this year; but we are thankful, anyhow, for the 6544 which we number to-day, Aug. 28.

REMEMBER THE MEETING OF THE OHIO BEEKEEPERS.

WE want every bee-man, who can afford the time and expense, to be on hand Thursday and Friday, to keep up the reputation of our fair State in honey matters as well as in other things.

STEEL CARPET-TACKS.

THESE are now made on the plan of the wire nails, and we can furnish them in two-ounce packages at 5c per package; or in half-pound packages at 15c per package. If wanted by mail, add 1c per ounce extra for postage.

STOPPING THE BEES FROM ROBBERING, EVEN IF IT IS SUNDAY.

ONE of the friends takes me to task for setting the apiarist at work stopping the bees from robbing, while I went to church. He is mistaken. We all went to church, and we always do all go to church—that is, so far as the bees are concerned; but if I should discover the bees were robbing badly, just as it was church time, I should by all means stay at

home as long as it might be necessary to stop robbing, but not any longer.

SABBATH-BREAKING AND FALSIFYING.

YOU will notice that the bee-man who slandered friend Muth (mentioned on page 589) says he examined his bees on "Sunday." May be that is one reason why he has got to be so awfully untruthful; for Sabbath-breaking, as a rule, opens the way to other grievous sins.

CALADIUM ESCULENTUM.

AFTER the letter on page 496, in regard to this plant, was printed, we sent to James Vick and got one of the bulbs. To-day, although it has only two leaves, they are both exuding what seems to be pure water. The water forms in a large globule in the center of the leaf, and once in a while drips from the point of the leaf, just as Mary said it would. The plant is a wonderfully rapid grower, and is a great curiosity in the center of our coleus bed on our front lawn.

OUR THIRTY-FIVE-CENT WAX-EXTRACTOR.

THIS has been improved recently, by using a retinned wire-cloth sieve, making it much less liable to rust, and more durable. Small bee-keepers who have only a limited amount of wax to render, will probably find this the cheapest, cleanest, and most economical arrangement they can use. Just throw your bits of refuse wax into the sieve, packing it down if you choose, or squeezing it up into a ball. When you get a sieve full, set it into the dish-pan, which pan should be about half full of boiling water. Set the whole into the oven until the wax is all melted out and gone through the sieve; then lift out the arrangement and set it away to cool. The wax will be found in a nice cake on top of the water.

AN IMPROVEMENT ON THE GLASS HONEY-PAILS.

MORE than one of the friends have been annoyed to find that when one of these pails has been used for honey, that the honey will leak out where the bail is attached, when the pail is thoughtlessly turned over. I presume the manufacturers made them this way because they were primarily intended for jelly, and articles that do not run readily. This difficulty is now entirely removed, however, and the pails are very much improved in other respects, besides the following reduction in prices:

Price of the half-pound, 5c; 10, 43c; 100, \$4.00; 1000, \$35.00.

One-pound, 5c; 10, 48c; 100, \$4.50; 1000, \$42.50.

One and a half pound, 10c; 10, 75c; 100, \$7.00; 1000, \$65.00.

Please order only in the above quantities, as they are packed in boxes of 10 and boxes of 100. We are now buying these in such immense quantities that we are enabled to give the above greatly reduced rates. The 2-lb. Muth honey-jars are also reduced to \$6.50, instead of \$7.00 as given in our price list.

A CARPENTER'S SAW FOR ONLY FIVE CENTS.

SINCE the low price of iron and steel, tools of many kinds have cheapened wonderfully. When I was enabled to get a nice little saw for the women-folks for only 25 cts., I thought I had accomplished wonders; but now a firm in the east have sent me samples of a little saw, intended for juveniles, but made of so good a quality of steel that they may be put in order so as to do a great many kinds of light work with wonderful facility. I first saw our boy

using one, who crates our cages of bees, and he declared that it was a tiptop tool for that kind of work. The blade is $4\frac{1}{2}$ inches in length and has a good wooden handle, like small-sized saws such as carpenters use, and yet we are enabled to afford it for the insignificant sum of only 5 cts. Postpaid by mail for only 8 cts.

PORTULACCA AS A HONEY-PLANT.

THE friends will remember that we mentioned this about a year ago. We have now a larger bed than we had last year, and during the middle of the forenoon it is to me one of the most beautiful sights furnished by any one plant of the floral kingdom; neither do I know of any other that attracts such a great number of bees as does this during the time of day when the flowers are open. Every bee-keeper ought to have a portulacca-bed. The plant is very hardy, and will grow on almost any kind of soil, and it takes only five cents to get a paper of seed that will give you a wonderful variety of colors; and as you glance from one shade of color to another, you find yourself unable to determine which is the most beautiful. We can mail a package of seed of the above, on receipt of the price.

OUR CARNIOLAN BEES.

YES, they are hatched out. Those from the queen friend Benton marked "best," look (as I suspected they would) so much like black bees that I think I should have pronounced them so, had I not known differently. They have, however, a downy-bluish appearance that our blacks never have; and, in fact, were it not for the fact of the absence of the yellow bands, they would very closely resemble the Holy-Land bees when first hatched out. Well, we had two queens, as you may remember; and the one that was not marked "best" produces very fair Italians, and her young queens are also yellow, like Italians. This queen has probably met an Italian drone, or else our apiarist got her swapped by some means, although he declares it is impossible, and he is too careful a man to make it very probable. No matter; we are content to pay the price of two queens for getting one genuine Carniolan. Her young queens—that is, the young queens from the one marked "best"—are black, or quite as dark as native queens. The Carniolan mother is now quite a good-sized queen, and is of a dark copper or leather color. We shall have young queens laying in perhaps a week or ten days. The price will be \$1.50 for what we have to spare this fall. Of course, they will be untested.

DO GOOD TO THOSE THAT HATE YOU.

IN newspaper controversies, and controversies of almost every other sort, each party, as a general thing, seems to think it incumbent on him to tell every thing he can, that will be damaging to his opponent. He seems to take it for granted, that the more crookedness and evil he can discover and bring to light, the greater his chances for success. Success in what? Why, I suppose in making out himself to be a good man, and "t'other party awfully depraved." But, how does this match with the injunction Jesus gave us at the head of this editorial? Of course, it doesn't match at all. "But," you may urge, "is it right for us to suffer by misrepresentation, false charges, and other like injustice?" If by defending yourself from these false charges it is going to result in serious damage to your opponent, I do not believe it is best to try to defend our-

selves. There is no lack of instruction in the Bible on this point. Paul says, "Why do ye not rather take wrong?" and, again, Jesus says, "I say unto you, resist not evil;" and furthermore, "Blessed are ye when men shall persecute you and revile you," etc. I have thought the matter over, dear friends, a good deal, and prayed over it, and I believe a great many times it is not best to make any reply at all. Suffer the wrong in silence, for the time being, but take great care that your general conduct with your fellow-men be such that the world will be apt to say, as soon as the slander is started, "There is surely some mistake in this charge. From what I know of Mr. A., and his general conduct in life, I can not for a moment believe a word of it." Now, my friends, don't you believe this would be the best way? It will have this effect, at least: The controversy and jangling will probably stop where it is. If you don't agree with me, and think it best to "pay every man back in his own coin," suppose you try the latter plan, and make a note of how it turns out, and see whether it pays or not. Then try "t'other way" and see how that turns out, and make a note of it.

CONVENTION NOTICES.

The Southern Illinois Bee-keepers' Convention is to be held in Duquoin, Thursday, October 1, 1885. Every one that has bees is invited to attend. New officers are to be elected. F. H. KENNEDY, Sec.

WM. LITTLE Pres.

The Progressive Bee-keepers' Association of Western Illinois will meet in Macomb, Ill., on Thursday, Oct. 15, 1885. Let everybody come and have a good time. Good speakers are expected.

J. G. NORTON, Sec.

The Wabash County Bee-keepers' Convention will meet in G. A. R. Hall, North Manchester, Ind., Oct. 10, 1885. All bee-keepers are earnestly requested to be present. J. J. MARTIN, Sec.

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they want to dispose of, we will insert notices free of charge, as below. We do this because there is hardly value enough in these queens to pay for buying them up and keeping them in stock; and yet it is oftentimes quite an accommodation to those who can not afford higher-priced ones.

I have 3 or 4 prolific Italian hybrid queens at 50¢ each. I will take extracted honey or foundation for some, or money. C. L. HILL, Dennison, O.

If any one wishes them, I will sell 25 or 30 black queens at 25¢ each. W. T. LYONS, Decherd, Franklin Co., Tenn.

I have a number of hybrid queens which I will sell for 40¢ each, or three for \$1.00, if ordered at one time. JAMES P. STERRITT, Sheakleyville, Mercer Co., Pa.

I have a lot of black and hybrid queens for sale. Hybrids, 30¢; blacks, 20¢; large, young, and prolific; will send by return mail, and guarantee safe arrival. J. A. BUCKLEW, Clarke, Ohio.

Ten fine Italian queens, reared this season, and purely mated, by return mail, for \$5.00. We are uniting our nuclei, and must dispose of them.

GEO. W. & S. H. FOTMER, Independence, Kenton Co., Ky.

100 COLONIES OF BEES FOR SALE.

L. C. WOODMAN, Grand Rapids, Mich.

DADANT'S FOUNDATION FACTORY, WHOLESALE AND RETAIL. See advertisement in another column.

DADANT'S FOUNDATION

is asserted by hundreds of practical and disinterested bee-keepers to be the cleanest, brightest, quickest accepted by bees, least apt to sag, most regular in color, evenest, and neatest, of any that is made.

It is kept for sale by Messrs. A. H. Newman, Chicago, Ill.; C. F. Muth, Cincinnati, O.; Jas. Heddon, Dowagiac, Mich.; F. L. Dougherty, Indianapolis, Ind.; Chas. H. Green, Berlin, Wis.; Chas. Hertel, Jr., Freeburg, Ill.; Ezra Baer, Dixon, Lee Co., Ill.; E. S. Armstrong, Jerseyville, Illinois; Arthur Todd, Germantown, Philadelphia, Pa.; E. Kretschmer, Coburg, Iowa; Elbert F. Smith, Smyrna, N. Y.; C. T. Dale, Mortonsville, Ky.; Clark Johnson & Son, Covington, Ky.; King, Aspinwall & Co., 16 Thomas St., New York City; C. A. Graves, Birmingham, O.; M. J. Dickason, Hiawatha, Kan.; J. W. Porter, Charlottesville, Albemarle Co., Va.; E. R. Newcomb, Pleasant Valley, Dutchess Co., N. Y., and numerous other dealers.

Write for samples free, and price list of supplies, accompanied with 150 Complimentary and unsolicited testimonials, from as many bee-keepers, in 1883. We guarantee every inch of our foundation equal to sample in every respect.

CHAS. DADANT & SON,
Hamilton, Hancock Co., Illinois.

51tdf

The best Queens out.

I will furnish queens from July 1 to September 1 for one dollar; warranted tested, \$2.00; after then the price will be the same as in A. I. Root's list. Queens all bred from an imported mother.

G. F. SMITH,
Bald Mt., Lackawanna Co., Pa.

16tdf

FOR SALE.

20 Colonies of Pure Italian Bees in Langstroth frames, straight pretty combs, with honey, in DOUBLE-WALL OBSERVATORY HIVES; Been used two seasons with one-pound boxes, and for extracting. Complete on board cars, for \$8.00 per colony, or \$14.00 for the lot.

JAMES CRAIG,
MT. MERIDIAN, VA.

16 17 18d

For Sale. Six full colonies of bees in L. hives, on frames of wired foundation, \$8.00 each. They are strong, and have black and hybrid queens. I guarantee safe arrival.

IRA D. ALDERMAN, TAYLOR BRIDGE, SAMPSON CO., N. C.

ORDERS ALL FILLED.

We have a fine lot of queens now ready to ship. We claim to have the brightest yellow Italian bees in America. T. S. HALL, Kirby's Creek, Ala. 16-17d

PRICES REDUCED!

Until further notice I will furnish untested Italian queens at 80c. each; 6 for \$4.50. Warranted queens, 90c. each; 6 for \$5.00. All queens bred from my choice improved stock, and the cells built in full strong colonies. Safe arrival and satisfaction always guaranteed.

J. P. MOORE,
MORGAN, PENDELTON CO., KY.

Wanted. A competent man to conduct an apiary, also a poultry ranche. Address with reference, L. A. FITZPATRICK, Hyde Park, Phillips Co., Ark. 16-19db

HUTCHINSON'S ADVERTISEMENT.

We are now making a specialty of rearing fine Italian queens. All queens are bred from the purest and best of mothers, and the cells built in full colonies. We have one of A. I. Root's very best, selected, tested, imported queens, also quite a number of very superior home-bred queens from the apiary of "Cynla Linswik." Besides this we have our own original stock which was built up from Dadant imported stock and from queens obtained from several of our best breeders. We are not trying to see how cheaply we can rear queens, but how good ones we can furnish. No queens will be sent out that would not be used in the home apiary. Single queen, \$1.00; six for \$5.00; twelve or more, 75 cts. each. Tested queens, \$2.00 each. Full colonies, \$5.00 each. Make money orders payable at Flint. Address

W. Z. HUTCHINSON,

HONEY COLUMN.

CITY MARKETS.

CINCINNATI.—*Honey.*—No change has taken place in the general feature of the market. Demand is slow for extracted honey, with an abundance on the market. Depression in other branches of business, and low prices, have their bearing upon honey. Better prices will, in my estimation, not be obtained until a general revival of business takes place; our most ardent desires to the contrary notwithstanding. Custom has to be made, even at the short crop of this season. Small lots only of new comb honey make their appearance, and are sold readily, but demand is slow in proportion. Extracted honey brings 46¢ on arrival, and choice comb honey 15¢ 16¢ in a jobbing way.

Beeswax is in fair demand, and arrivals are good. We pay 20¢-24¢ for good yellow.

The following explanation in regard to markets seems to be necessary in order to post some of our bee-keeping friends, and save them from disappointment. When quoting prices "on arrival" I mean to say that honey will bring about the price quoted, or that a figure within the range given will appear reasonable or acceptable to a purchaser. I quote, as near as possible, the prices at which I am buying and selling. I do not mean to say that purchasers are waiting for the arrival of honey, and are anxious to buy at those prices quoted, nor that I am willing to pay those prices on arrival for all the honey that may be shipped here. This latter would require a larger capital than I and two more of the largest dealers in America possess. It is unpleasant for us to be overrun with honey for which I will not pay on arrival, unless agreement has been made previous to shipment.

CHAS. F. MUTH,

S. E. Cor. Freeman and Central Avenues,
Sept. 12, 1885. Cincinnati, O.

NEW YORK.—*Honey.*—There is very little change to note in the honey market since our last, except more activity. New crop comb honey is arriving quite freely, and selling readily at following prices:

Fancy white clover, 1-lb. sections, per lb.	14¢ 15¢
" " 2-lb. "	12¢ 13¢
Fair to good 1 and 2 lb. "	10¢ 11¢
Fancy buckwheat, 1-lb. "	11¢ 12¢
" " 2-lb. "	9¢ 10¢
Extracted white clover, "	6¢ 7¢
" buckwheat, "	5¢ 6¢

Sept. 8, 1885. McCaul & Hildreth Bros.,
34 Hudson St., cor. Duane St., N. Y.

DETROIT.—*Honey.*—The market is improving; good honey is bringing 17¢ 18¢. A. B. WEED,

Sept. 11, 1885. 407 Woodward Ave., Detroit, Mich.

BOSTON.—*Honey.*—Best white 1-lb. sections, 15¢ 18¢; 2 lbs., 14¢ 15¢; extracted, very low at any price. *Beeswax*, 25¢ 30¢. BLAKE & RIPLEY,

Sept. 11, 1885. 57 Chatham St., Boston, Mass.

CLEVELAND.—*Honey.*—The market at present is pretty well supplied with new honey by neighboring apiarists from wagons, which makes the demand from our stores rather light. The price of 14¢ 15¢ per lb. for best white 1-lb. sections is well maintained, however, and we may look for better sales in the future, particularly if the clouds of dull times, which are predicted to be breaking, leave the commercial horizon bright and clear before long. Extracted, 6 to 7¢. *Beeswax*, 22¢. A. C. KENDEL,

Sept. 10, 1885. 115 Ontario St., Cleveland, O.

CHICAGO.—*Honey.*—Market is quite good for this season of the year; receipts are heavier, and sales also larger than at last writing; 15¢ 16¢ per lb. is the price obtainable at present for comb honey of best style and quality. Extracted, 5¢ 8¢. *Beeswax*, 21¢. R. A. BURNETT,

Sept. 10, 1885. 161 So. Water St., Chicago, Ill.

ST. LOUIS.—*Honey.*—Our market continues quiet, a small demand for extracted in barrels; 46¢ 47¢ for Southern. New white clover in cans, retail, 85¢ 90¢. Comb honey, some light inquiry for white clover, choice, 16¢ 17¢ retail. *Beeswax*—very dull; stock large, 21¢ 22¢. W. T. ANDERSON & Co.,

Sept. 10, 1885. 104 N. Third St., St. Louis, Mo.

MILWAUKEE.—*Honey.*—New honey not very plentiful. Demand good. Extracted, quick sale at 8¢ per lb. Comb, 1 and 2 lb. sections, white, 15¢ 17¢; dark, 12¢ 14¢. A. V. BISHOP,

Sept. 10. 112 W. Water St., Milwaukee, Wis.

WANTED.—500 lbs. comb and 1000 lbs. extracted honey. I will pay cash, 14¢ for comb and 7¢ for extracted. Honey must be delivered here in good shape; must be all clover or basswood; comb may be in any size of section less than 2 lbs.; all well filled, sealed, and straight. Extracted must be thick. OLIVER FOSTER, Mt. Vernon, Iowa.

WANTED.—Extracted basswood honey, in lots convenient to handle (100-lb. lots preferred).

J. G. LEHDE, Gardenville, Erie Co., N. Y.

FOR SALE.—2000 lbs. of white-clover honey (extracted), in barrels. I will deliver it on cars at Ionia, on the C. M. & St. P. R. R., or at Nashua, on the I. C. R. R., at 7 cts. per lb., net.

HENRY L. ROUSE, Ionia, Iowa.

FOR SALE.—4 barrels of fine linn extracted honey, ripe, and of the best quality, seven cents per lb., delivered on board cars here.

J. B. MURRAY, Ada, Hardin Co., Ohio.

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they want to dispose of, we will insert notices free of charge, as below. We do this because there is hardly value enough to these queens to pay for buying them up and keeping them in stock, and yet it is oftentimes quite an accommodation to those who can not afford higher-priced ones.

I have 15 prolific hybrid queens to dispose of, at 25¢ each, in stamps; 5 for one dollar.

W. A. SANDERS, Oak Bower, Hart Co., Ga.

I have 8 hybrid queens, this year, 2 nearly black, others choice queens; \$2.25 for the lot, and safe arrival guaranteed; 3 for \$1.00. Who wants them?
B. F. CARROLL, Dresden, Texas.

Ten fine large yellow hybrid queens, six weeks old, bred from pure Italian mothers, which I have taken from a neighbor's apiary, at 25¢ each; five dark, at 15¢ each, ready to go by first mail. Safe arrival. F. H. SCATTERGOOD, Winona, O.

I have several black and hybrid queens that I will sell at 25 and 35¢ respectively. Safe arrival guaranteed. J. H. GINDLING,

Ohlman, Montgomery Co., Ill.

HONEY AND BEESWAX.

We are now in the market, and will be during the entire season, for all honey offered us, in any quantity, shape, or condition, just so it is pure. We will sell on commission, charging 5 per cent; or if a sample is sent us, we will make the best cash offer the general market will afford. We will handle beeswax the same way, and can furnish bee-men in quantities, crude or refined, at lowest market prices. Our junior member in this department, Mr. Jerome Twichell, has full charge, which insures prompt and careful attention in all its details.

Sample of comb honey must be a full case, representing a fair average of the lot. On such sample we will make prompt returns, whether we buy or not.

15 2db **CLEMONS, CLOON & CO.,**
Kansas City, Mo.

GET THE BEST BEE-BOOK.

The third edition of **The Bee-Keeper's Handy Book** contains 300 pages and 100 fine illustrations, also a likeness of Rev. L. L. Langstroth, and the late Moses Quinby, two of the most noted bee-keepers of the world. Two hundred pages of this work are devoted to practical bee-keeping, and 100 pages to the best and simplest methods for rearing queens. Mr. Langstroth says this work is the "best authority on queen-rearing," and J. E. Pond says, "It is the best bee-book published in the English language." Send for prospectus. **HENRY ALLEY,** Wrenham, Mass.

QUEENS AT REDUCED PRICES.

Owing to the scarcity of money I will sell my warranted Italian Queens at \$8.00 per dozen; two dozen for \$15.00.

SECRETION; WHAT IS IT?

HOW AND WHERE DO THE BEES GET WAX?

A. J. COOK:—Please answer this in GLEANINGS: Do bees digest honey, or do they manufacture honey into wax? Please explain it plainly, as there are parties here who do not agree with your theory in your Manual. I have one, but it is one of the old edition.

J. W. BITTENBENDER.

Knoxville, Iowa, Aug. 13, 1885.

Answer by Prof. Cook.

The question of Mr. Bittenbender's serves admirably as a text for an article which I have long desired to write for GLEANINGS, but for lack of time have deferred till now. I wish to consider the relation of nectar to honey and to the food of larval bees, the relation of honey to wax as secreted by bees, and the relation of the sap of trees to the nectar which is secreted by their flowers or other glandular extra-floral cells.

Secretion, whether of saliva or spittle, in our own salivary glands, whether of milk by any of the mammals, or whether of wax by bees, is always accomplished by cells specially developed for the purpose. These cells may be just blind sacks of protoplasm, as the nectar-glands of plants, or they may be cells conducting to tubes when, as in case of our salivary glands, or the glands in the head and thorax of bees (see Manual, p. 87), they are called racemose glands, from their resemblance to a bunch of grapes. It is the function of these glandular cells to take elements from some nutritive fluid, like the sap of plants or the blood of animals, and from some other substance—the secretion—not found in the blood, or in the sap, as the case may be. A se-

cretion, then, is not a substance simply eliminated from sap or blood; it is a new substance formed from the sap or blood, which, in the economy of the individual, shall be of some service. Thus our spittle or milk is not in the blood. The elements are there, but the spittle and milk are products of the glands, made from elements taken from the blood. So, too, the nectar of flowers, or plant-glands, is not in the sap of the plants, but is made by the gland-cells from elements in the sap. True it is, that these cells will sometimes eliminate foreign substances—may be toxic substances—which are in the blood. For instance, we may feed a cow poison, and find the poison in the milk. The poison is no part of the milk; but the glands, like good Samaritans, quickly spring to the aid of the purely eliminating organs, the lungs and kidneys, in the removal of the harmful substance of the blood.

In case of the poisonous honey discussed in GLEANINGS, I said I did not think it possessed the properties of the sap. First, the nectar is a secretion, and so is made from the sap, but is not the sap. True, the glands might remove a poisonous element in the sap, possibly—as animal glands do upon occasion—but this is not likely, as the poison is not hurtful to the plant, but a normal substance, and there is no occasion for its removal. Again, this poison is always in the sap, yet we have not heard of this honey as poisonous before—not till this year. Plants are in like condition every year, and do not by accident get poison as do animals, which may need elimination. I think it far more likely that the bees got some real poison from other sources; or possibly good honey was a poison to

the persons afflicted, as all honey seems to be poison to some people. "What is one person's meat is another person's poison."

Only a few years ago I received honey from New York State which poisoned several persons, yet we have not heard of any similar poisoning since. It is more than likely that what was true in one case was also true in the other.

To answer the question as to wax. Bees take honey as food. This is digested and absorbed, when it becomes blood, which is the nutritive fluid of the bee, but is not honey, and quite likely contains no honey for the most if not all the time. From this blood the wax-glands secrete the wax scales. Thus the wax of the bee has the same relation to the honey eaten by the bee, that the cow's milk has to the hay which she eats. As stated in all the last editions of my "Bee-Keeper's Guide," from the eighth thousand to the thirteenth thousand inclusive, nectar and honey are not the same. We feed cane sugar to bees, and we get honey sugar, which is quite different in the comb-cells. So nectar is largely cane sugar, and is neutral, while the honey is a different sugar, and is acid. Thus we may say that honey is digested nectar, which is fitted in such digestion to be absorbed and assimilated. Recent experiments have shown that, when we eat cane sugar, it is digested in our stomachs, and in this act converted into a sugar like, if not identical, with honey sugar, whereby it is fitted for absorption and assimilation. Thus we have reason to believe that honey is the best form of sugar, as here the bees have done what otherwise our own digestive energies must have performed.

It is quite likely that honey sugar is most like liver sugar, and that both are widely removed from corn glucose, though all give the same chemical reaction with the copper salts. This view of the superior excellence of honey as a food, gives new force to the commendation, "A land flowing with milk and honey."

Again, bees feed a creamy substance to the larval bees. This substance contains not only oxygen, carbon, and hydrogen, the only elements of pure honey or sugar, but also nitrogen. This last the bees get from the pollen, which must surely be present to rear brood. True honey may contain a little pollen; but to rear any considerable amount of brood, pollen must be present in greater quantities—stored in the cells. This honey and pollen is very perfectly digested by the bees, and so is fitted for absorption, else it would be useless, as the larval bee is not fitted to digest. It is not known whether the digestive juices that produce this change are all formed in the stomach or not. Quite likely the large glands in the head and thorax may aid. This is a question difficult of solution, but will doubtless one day be solved.

A. J. Cook.

Agricultural College, Lansing, Mich.

I have always supposed that the wax secretion in the body of the bee was formed in a similar way to the formation of tallow and lard and fatty matter, in the bodies of our domestic animals. They eat grass, hay, and grain. The nutritive properties of these different kinds of food go into the blood. When all the different functions of the animal are properly performed, there is a residue of a very rich concentrated substance. This substance accumulates as fat. In the body of the bee the process is the same, only

that these flakes exude so as to come out between the scales composing the bee's body. They are not identical in composition with lard and tallow, but they are in many respects similar. With the bee it seems to be a provision of nature—a substance just exactly right to build the cells of the honey-comb. Sometimes these wax scales stick out in such protuberances that they curl up. A few days ago a friend sent us a bee by mail, asking what sort of a fungoid growth it was that was sticking out of and adhering to the bodies of many of his bees. There was no trouble at all, of course. His bees were simply secreting unusual quantities of wax. When we feed sugar heavily in the fall, to get the bees ready for wintering, they often secrete such quantities of pearly-white wax scales that they fall to the bottom of the hive in the form of a dust, and under the microscope they look much like fish-scales. Of course, there must be a waste when this happens; for it doubtless requires a good many pounds of sugar to make one pound of this white wax, just as it requires a good many pounds of corn to make one pound of beautiful white leaves of lard in the body of a hog.

PROCEEDINGS OF THE OHIO STATE BEE-KEEPERS' ASSOCIATION.

REPORTED BY G. F. WILLIAMS.

IN giving this report it may be well to announce that, as the regular secretary did not make his appearance nor send any of the papers from the last meeting, we were unable to produce any minutes of said meeting, or even get a copy of the constitution and by-laws. Friend Williams was requested to act as secretary until the regular secretary should appear; but as said officer did not appear at all, the following report is entirely from Mr. Williams:

The bee-keepers of Ohio met, as previously announced, at the State Fair-grounds, and assembled at 9:30 Thursday morning, in room over Avorian Hall. A. I. Root, Pres., called the meeting to order.

Dr. Besse introduced the subject of

BEES TRESPASSING.

and cited the case of a Wisconsin farmer who had brought suit against a bee keeper whose bees, he claimed, trespassed on his clover fields. The doctor said, "I don't think bees ever trespass. I think it preposterous for a man to sue for bees trespassing. Bees are an advantage to all farmers, by assisting nature in the fertilization of flowers."

C. E. Jones.—I never had any complaint, and think them a blessing.

A. I. Root.—In my opinion, nothing can be made out of the case.

Secretary.—In our town a neighbor complains of bees trespassing in the kitchens, and of eating their grapes.

A. Benedict.—People think bees puncture grapes; but this is a mistake. They work on grapes after wasps, and other insects having strong mandibles, puncture them. They never injure sound fruit.

President.—We have several hundred grapevines right over our hives, and our grapes are never injured by the bees.

Dr. Besse.—Bees will never injure the tender Delaware grape, unless the skin is first ruptured. Bees are a benefit to corn-growers.

A. Benedict.—After grapes are bursted they soon rot any way, and might the bees not as well get the sweet from it as to let it waste? Bees are a benefit to all fruit-growers.

Dr. Besse.—Fruit-growers ought to be thankful

for the bees. If there were no bees there would be little fruit.

President.—A Massachusetts fruit-man once compelled a bee-keeper to remove, because he claimed that his bees injured his fruit. A trial of several seasons without the bees was a failure, and the bee-keeper was prevailed upon to come back.

CIDER - MILLS.

Mr. Benedict.—I am satisfied that cider-mills injure bees.

Dr. Besse (who seems to always take the opposite side, in order to draw out all points).—Cider-mills are a good thing for bee-keepers in killing off some of our bees, so that they do not go into winter quarters too strong.

C. E. Jones.—I lost 73 colonies, which had plenty of clover honey; cider carried in killed them; had better spent \$100 in screening the mill.

President.—As a means of harmony I suggest that bee-keepers furnish some kind of screen to keep out the bees. We furnished one for a neighbor cider-maker which kept out flies, etc., as well as bees, and cost only \$2.00.

E. R. Root moved that the President appoint a committee to see that a suitable building be erected by the Agricultural Society of the State on the new fair-ground, for the use of bee-keepers, as a place of exhibition and meeting. Seconded and carried.

Dr. Besse, Delaware, chairman; *C. E. Jones*, Delaware; *Aaron Benedict*, Bennington, were appointed the committee.

Next was proposed the subject of having the Ohio Agricultural College take up Apiculture as a branch of study. The President said he thought the college ought to take such measures, and that it would elevate bee culture in our State.

Dr. Besse moved that a committee be appointed to confer with the directors of the Agricultural College, to have a station of bee culture established there. Seconded and carried. *Ques.*—What is to be the object of this department?

Dr. Besse.—The object is to test for best bees, best methods of management, to report from time to time, and to educate students in bee culture.

Committee appointed were—*Dr. Besse*, chairman; *J. W. Newlove*, *W. Oldroyd*, *Dr. Mason*, *A. I. Root*, *Chas. Muth*, *Dan White*.

Perhaps I might mention here, that before returning home I had a conversation with some of the friends at the Agricultural College, in regard to the above matter, and they declared that it is out of the question to take up any thing more just now, without more funds and more intelligent helpers. There are already too many things started that amount to nothing, because of the lack in the direction above mentioned; or, to put it briefly, "too many irons in the fire" as it is. I am not competent at present to say just what needs to be done. But it seems to me there is no reason why we should be behind the State of Michigan, or any State, for that matter.

WHAT IS THE PROPER SIZE OF A COLONY TO START IN WINTER QUARTERS?

Dr. Besse.—I think too many bees do not winter as well as a small colony.

A. Benedict.—I can not quite agree with *Dr. Besse*. I want a large colony of bees; a small one will eat much more honey in proportion to its size than a large one, to keep up animal heat.

C. E. Jones.—My experience in this: Get a colony in as nearly a natural condition as possible, large, and plenty of honey.

HOW MANY BEES ARE NECESSARY FOR SUCH A COLONY?

Dr. Besse.—About 3 lbs.

A. Benedict.—I winter out of doors.

Dr. B.—I winter in the cellar.

Mrs. Culp.—I don't care for such large colonies. I don't stimulate in the fall; am satisfied small colonies are the best. I winter in chaff hives, and stimulate in the spring.

Dr. Besse.—Winter half the bees, and extract and sell half the honey.

President.—*Dr. Besse* and *Mrs. Culp* may be right, but I think there ought to be caution used here in the use of terms. A large colony will sometimes

contract in cool weather to the size of a popcorn ball, and winter well.

Dr. Besse.—If you stimulate in fall, feed early enough so that young bees can have two or three flights before they cluster for winter.

WHEN WOULD YOU FEED?

Dr. Besse.—Any time—the sooner the better.

President.—We have the best results by feeding gradually. Feed, say, $\frac{1}{2}$ lb. every night; feed during September if possible.

Mrs. Culp.—I think my plan of setting away full combs, and giving them in the fall, the best plan.

Dr. Besse.—We should throw out the uncapped honey before going into winter quarters.

HOW MANY COMBS OF HONEY ARE NECESSARY TO WINTER A COLONY?

Dr. Besse.—Twenty-five lbs. of honey.

President.—Five full combs.

POOR SEASONS.

President.—Bee-men are complaining of a poor season. I should like to inquire if it is the fault of the season or the apiarian.

Dr. Besse.—May be the fault of the supply-de-der(?). You should make $\frac{1}{2}$ -inch space for bees between sections; bees will then go up sooner.

C. E. Jones.—Don't put on too many sections in a moderate season at one time.

WHERE IS THE BEST HONEY LOCALITY IN THE U. S.?

Answers—Central Ohio; California in a good season; Florida; basswood locality of Wisconsin and Michigan.

Dr. Besse.—Ohio extracted and comb honey, taken by me to the exposition at New Orleans, took the first premium.

A. Stanger.—Hardin Co. is as good as any county in the State, for honey.

Mrs. Culp.—Franklin Co. is a good locality. I tested one colony, and took 252 lbs. extracted honey.

Adjourned to 2 P. M.

HOW MANY COLONIES CAN BE KEPT IN ONE LOCALITY?

President.—That depends on circumstances.

AFTERNOON SESSION.

The subject of

MOVING BEES DURING THE WORKING SEASON

was first taken up.

Dr. Besse.—Move five or six swarms every evening. After bees are all in the hive, set the hives far enough apart to set others between them when moved next evening. Set a board, or three or four sticks of stave-wood, in front of the colony moved. I moved 100 colonies 250 or 300 ft., and very few bees, if any, went back. They were caught in a nucleus hive on the old stand. I would advise moving strongest first, then the returning bees would reinforce the weaker ones left.

A. Benedict.—When setting bees out of cellar, be sure to put hive on old stand.

Mr. Gordon, M. D., Mt. Vernon.—I have no trouble in moving bees short distances, and I don't think it makes any difference whether we set bees on old stand when taken out of cellar or not.

Mrs. Culp.—I set my bees further apart last fall, and saw no bad result. I was trying to see if I could make them do as I wanted, and I did.

Dr. Gordon.—I winter my bees out of doors, with corn-fodder placed around them, leaving an opening on south side, so the bees can fly on warm days. I move them together and set them on scantling two tiers high.

Mr. Morris, Fayette Co.—I wintered my bees in a bee-house for three years, successfully. I never set out of doors for a fly when quiet. The house has a brick foundation, double wall, 1 ft. space filled with sawdust; 1 ft. sawdust on top, cement floor.

President.—In regard to cellar wintering, there is a diversity of opinion and experience. Chaff hives seem to be the most practicable, with the variable winter weather we have in Ohio, and public opinion seems to be getting in favor of them.

A. Benedict.—Bees need more ventilation in winter than in summer.

President.—Our practice is to leave the entrance open full width all winter.

Mr. Goodrich.—I prefer cellar wintering; keep bees as near the freezing-point as possible, and think it best.

Dan White.—I think the cellar, with an experienced hand, the best place to winter, although I winter

in chaff hives out of doors. I lost half my bees last winter.

C. E. Jones.—The cellar is a good place to winter, if properly prepared.

President.—The cause of last winter's losses was poor stores and severe weather.

WHAT IS THE CAUSE AND CURE OF SPRING DOWDLING?

Mr. Morris.—Our spring losses were caused by there being too few young bees when we went into winter quarters.

Dan White.—The cure is plenty of young bees. *President.*—There is some mystery about spring dwindling. A colony dwindling seems to get discouraged, and will not even gather pollen. I am sometimes inclined to think it a disease of some kind, and may be contagious, affecting whole apiaries, and missing others in the same locality. A disastrous winter is a benefit, in one way, by making a demand for bees and honey.

IS SORGHUM INJURIOUS TO BEES?

President.—Yes, it is a dangerous winter food.

Mr. Morris.—Will bees degenerate by in-breeding?

C. E. Jones.—We had better introduce new blood.

President.—I don't think there is any danger of any harm arising from in-breeding.

WHO USES SEPARATORS?

Dr. Besse.—I don't, and think it is better without them.

Secretary.—I have abandoned them. To get the nicest and straightest combs, use 1½-inch sections; such a section, 4½×4½, will hold a pound, and you can have as many rows of sections as you have brood-frames—the frames being spaced 1½ inches; reverse your sections.

A. Benedict.—I use 1½-inch sections with no separators.

It seemed to be generally understood that we could all dispense with separators by using narrower sections.

Adjourned to meet in Sec. Chamberlain's office, in State House, at 7 o'clock.

EVENING SESSION.

The question was asked, Which is preferable, natural swarming or division?

Dr. Besse.—Divide them. I would rather divide three than five one natural swarm. By division you have complete control of the bees. I raise early queens from best stock. Get early drones by inserting a drone comb in the center of full colony. When a colony indicates swarming I divide, putting old queen on new stand and new queen on old stand.

C. E. Jones.—I am in favor of natural swarming. I also raised early queens. I make two swarms out of a large one. I think it more natural for them to swarm.

Secretary.—I let my bees swarm naturally, or I divide them, according to the circumstances and conditions of a colony at the time. No general rule can be laid down. It may be best to divide one, and best to leave another to swarm. You must learn to determine by experience. I clip my queens.

Mr. Pierson.—I prefer natural swarms. I clip my queens also.

President.—Where you desire increase, divide. If you wish honey and no increase, let them swarm if you can't help it.

Wm. Oldroyd described how he took a swarm out of a very high tree, which led to a discussion on hiving swarms.

Mr. Benedict.—I would smoke a swarm down from a high limb by tying burning rags to a piece of iron fastened to a long pole, or I would use a swarming-box. I believe in artificial swarming, and I don't believe in it. I divide by the "drumming" process, which is the most natural. The bees thus swarmed are filled with honey; and as a swarm takes about 6 lbs. of honey with them, this gives them a start. I put the old queen on the new stand, and run the new queen in the other part. In 15 days I can drum again. By putting in the new queen I always have the hive full of bees.

Dr. Besse.—Bees usually alight on low bushes.

Wm. Oldroyd.—That is not my experience.

Dr. Besse.—To have a high swarm I would shake the bees off on a pole, to which a caged queen is fastened.

C. E. Jones.—In swarming time I watch my bees closely. I can tell within 10 minutes of the time when a swarm is going to come out. Bees generally alight low. I take the swarms from a limb in a

swarming-basket with a spring lid. I generally catch swarms in a basket just as they are coming out. If two or three swarms alight together, dump them on a sheet; catch the queens, and divide equally as nearly as possible.

HOW CAN WE TELL WHEN A COLONY IS GOING TO SWARM?

Ans.—By the commotion in the hive and in front of it. I use a hive with glass on the sides.

A. Benedict.—I separate my swarms with my smoke-pole, holding it near the swarm already settled, which will prevent others from settling.

President.—We used to keep a caged queen to catch swarms, as stated by Dr. B.

Secretary.—Mr. Ed. Miller, a neighbor bee-man, who is a carpenter by trade, and who is away from home during the day, clips his queens, and during the swarming season sticks a stout bush, with some branches on, a few bees in front of each hive, in the ground. When a swarm comes out his "better half" catches the queen, cages her, and fastens the cage in the bush. The bees settle on the bush, and at noon or in evening, after work, Mr. M. hives them.

Adjourned to meet at fair ground, Friday morning at 9 o'clock.

FRIDAY MORNING SESSION.

In the absence of the President, Mr. Benedict acted as chairman.

HOW CAN WE GET THE MOST HONEY?

Mrs. Culp.—I get more than twice as much extracted honey as comb honey, by putting in empty frames.

Secretary.—Last season I had a large number of sections filled with empty comb, and I believe it was due to this fact that I had my good yield of comb honey this season. I think if we can always manage so as to get our sections filled with comb we can get as much comb as extracted honey.

Mr. Benedict.—We advise beginners to go slow in extracting, and learn the business, or they may produce bad results, and get discouraged. I use a movable bottom-hive, and tier up in extracting. If the colony swarms, I have it on foundation combs under the old colony, placing a wire cloth between the two for a day or two. The queen begins to occupy lower story; and as the bees hatch out above, the honey is stored in the frames. By this method I get a large body of bees at work in a single hive.

Mrs. Culp.—My practice is similar to that described by Bro. Benedict.

A. Benedict.—In working for comb honey I use the same method of keeping my colonies strong by hiving back the swarm. If I have swarms by themselves, I take a section-rack from the old hive and put it on a new one.

Dr. Besse.—How soon do you extract after putting swarm back?

Ans.—In two or three days, or as often as necessary—whenever honey is partly capped.

Dr. Besse.—This, in my experience, won't work well. If you extract next day, the queen will go up and occupy frames, and bees will build drone-comb below. I have no particular method of working for extracted honey. I usually extract from brood-chamber as soon as queen gets crowded. I tier up two or three stories high; always let bees cap about two-thirds of my honey before extracting. Bees work downward; put empty hive under full one.

A. Benedict.—In tiering up section cases, always put an empty one beneath a full one.

The convention then adjourned, to meet some time in January.

STATE FAIR EXHIBITS, AND NAME TO WHOM PREMIUMS WERE GIVEN.

There was on exhibition by a number of bee-keepers, honey, both extracted and comb, some very fine bees and fixtures, and implements of all kinds. Mr. Goodrich exhibited a nice lot of comb honey, one-pound sections put up in small shipping-cases, also a very fine display of extracted honey put up in many different styles. He received first premium on comb honey, first on general display of comb and extracted, second on extracted.

Mrs. Culp exhibited some very fine wax, on which she took first premium.

Dr. Besse's display of extracted honey was very fine—the nicest display we ever saw. He took first premium on extracted honey.

C. E. Jones took second premium on display of comb honey, and first premium on full colony and manipulation of same.

Brigham and Clayburn exhibited some fine comb honey, and took first premium on single crate of honey.

Aaron Benedict exhibited some of the finest Italians we ever saw, and we have seen and examined many strains since we have been a bee-keeper.

Earl Clickinger also exhibited a fine nucleus.

NAME AND RESIDENCE OF SOME OF THE PARTIES IN ATTENDANCE, WITH TABULATED REPORT OF THE SEASON.

Names and Post-Office Address.	Colonies now in	hives in Sept. 1st.	Swarm (Ct.)	Lib. Honey.	Lib. Euc. Honey.	The Season.

EXTRACTED HONEY.

How to Produce an Extra-Fine Article.

FRIEND HEDDON IS TAKING THE MATTER IN HAND.

FRRIEND ROOT:—In visiting bee-keepers, I find that very few of our brothers know how or are willing to take the pains to produce a *nice* article of well-ripened basswood honey. It took me years to learn how to take and keep it in a perfect state, like comb honey. I wish every bee-keeper in America could sample my ten tons of basswood and clover honey. I am selling to a large number of producers, and about every one of them sends me a testimonial. I should like to send you a 100-lb. keg of such basswood honey as I think would build up a large demand for extracted honey, if *all* who raise it would produce a "dead ripe" article, and take the proper care of it. If you say so, I will send you by freight a 50 or 100 lb. keg, such as I am selling at 8 cts. per lb., F. O. B., and keg thrown in, and you may credit me just what you think it is worth, to be traded out with you in supplies, and I will then write an article, if you wish, giving directions how to raise it, and keep it thus perfect. That is, in my opinion, one of the "keys" to enlarging the demand for our product. JAMES HEDDON.

Dowagiac, Mich., Sept. 7, 1885.

Friend H., you have got right hold of one of the most important points, in my judgment, now before us, and I am inclined to think you are master of the situation, judging from the quality of the honey sent us last season. I am well aware that this letter and your forthcoming article will probably be good advertisements for you; but you ought to have a good advertisement. Besides, we expect to advertise honey for anybody so long as he produces a good article at a fair price. While reading your letter I recalled to mind the amount of paper that we used up a few years ago in arguing the respective merits of comb and extracted honey. Offering a fine article of extracted honey, in 50-lb. kegs at 8 cts. per lb., is worth

more than all the arguments that could be put into a large book. Send me a 100-lb. keg, and a 50-lb. keg. I want to see what they look like, each size, and I will pay you the same price for them that the other people do; and send along your article as well.

INTRODUCING VIRGIN QUEENS FIVE AND SIX DAYS OLD.

HOW FRIEND GOOD DOES IT SUCCESSFULLY.

I SEND you by this mail the kind of cage I use; and, by the way, it is a good cage for introducing any kind of a queen. I use the Alley method for obtaining cells. With his method we get nice straight cells. I leave the cells in the hive until the queens commence gnawing out, then I cut them out and daub honey on the end of the cells. If that is omitted, many of the queens will starve before they eat out. Then I put the cells in the wooden part of the cage, put the end of the cell through the hole that opens into the wire cage, shut the lid to the cage, and lay the cages in a queen-nursery or on top of frames of a strong colony. I now keep watch of them; and as fast as the queens hatch I remove the cells and fill the wooden part of the cage with the Good candy. The cages can now be laid on top of the frame of any strong colony until they are wanted, and there is no danger of their starvation, even if the bees do not feed them. Now, when the queens are five or six days old (and if they are eight or ten it matters not), I introduce them to nuclei or full colonies, as the case may be. Where they have been queenless for four days, simply swing the lid half way round, so as to give the bees access to the candy, and shove the cage down between two combs, and let the bees eat out the candy, and liberate the queen; and, as a general thing, I have a laying queen in five or six days.

This and last season I had about 100 of the cages in use, and I know whereof I speak. I think many make mistakes in trying to introduce to colonies that have not been queenless long enough.

Nappance, Ind., Sept. 3, 1885.

I. R. Good.

I will explain to our readers, that friend Good's cage consists, first, of a little elliptical-shaped box, something like an old-fashioned pill-box. It is made from a piece of $\frac{1}{2}$ -inch board with a half-inch hole bored through the center. This hole is covered on one side with a thin strip of wood, having a hole in the center large enough to let the lower end of a queen-cell pass through. The other cover has a wire nail at one end, allowing it to swing around to put in the cell, or fill the cavity with candy. Now, attached to the side where the point of the queen-cell is to come through is a little bag of wire cloth. This bag is made in such shape that it will go down between a couple of combs readily. There is something new in this arrangement. You wait until the cells are almost ready to hatch, and then when the newly hatched queen is seen to be down in the wire-cloth box, the cell is removed, and its place filled with Good candy. She is now among the bees of a good colony, and she has plenty of candy where she can get it, but the bees can not get it away from her. No doubt a virgin queen from five to ten days old could by this means be introduced to a colony that

had been three or four days queenless, and she would be ready to take her wedding-flight as soon as she is out. From what experience I have had with bees, I should think that there would be quite a good many losses, unless the one who had them in charge had by experience learned just how to manage every little minute point, as friend Good doubtless has.

FRIEND SHUCK'S REVERSIBLE HONEY-BOARD.

ALSO SOMETHING IN REGARD TO HIS REVERSIBLE HIVE.

FRRIEND ROOT:—Bro. Heddon's experience reminds me of my efforts to get comb honey in the brood-chamber of the hive some years ago, by dividing a large brood-nest with cases of sections. I invariably got queen-cells in all, except the division occupied by the old queen.

I have raised queen-cells in an upper story when the lower story was occupied by a laying queen. Ordinarily the cells are larger, and the queens of better color, when thus produced. The cells must, of course, be removed for the final emerging and perfecting of the queens.

More than one queen may occupy the same hive by keeping queen-excluders between them. The excluder must divide the entrance so that the occasional passing of a queen around it is prevented. Aside from the fact that the bees occupy the hive and surplus apartment in common, this is simply a modification of the tenement hive idea. After all, this is a question of arithmetic: A good queen will occupy just about so much space, whether in a hive by herself, or along with another queen.

I send you to-day a sample of my skeleton board, such as I use and sell with my invertible hives. The spaces are readily cleared with a piece of steel, the proper size. I like them for excluding queens when a swarm is hived, as the swarm can immediately go into the sections, and leave the queen upon the brood-combs. Also if a colony is stubborn about going above, I put the sections *under* the hive, with the skeleton board between; or, rather, turn the whole apparatus upside down, when the bees will be *obliged* to go into the sections.

This board may be modified by extending the metal strips on one end, and thus form a queen-excluding division-board when it is desired to keep more than one queen at liberty in the brood-chamber of the hives.

I first took the idea of this board from the Quinby five-piece honey-board, which I used until sections were introduced, when I adapted it to the use of them. Mr. Heddon's board is a different thing entirely. He cleats it all around so as to get his bee-space between it and the sections. I have my bee-spaces in the hive-body and in the section cases themselves.

If I ever want a drone and queen catcher, I shall get the Alley trap, unless some one invents a better one. Bees well managed do not swarm much. Colonies run for comb honey should not swarm to exceed ten per cent. If run for extracted honey, not more than five per cent; so there is little use for queen-clippers and queen-catchers. However, if I had a valuable queen which I dreaded to lose, I

should lose no time in getting a queen or drone trap.

J. M. SHUCK.
Des Moines, Iowa, Aug. 4, 1885.

Thanks for the honey-board, friend S., and also for the facts you give us. I will explain to our readers, that this honey-board is made of slats of pine, $\frac{1}{4}$ inch wide, kept at the right distance apart for excluding queens and drones, by a folded strip of galvanized iron tacked across each end. Your idea of inverting the hive so as to bring this queen-excluding honey-board, sections and all, under the hive, is a novel one. You will notice that it is in a line with friend Heddon's recent experiments. Your letter is dated Aug. 4, but it may have been written before friend Heddon's article.

CRYSTALLIZED HONEY-DEW.

FRIEND COOK GIVES US SOME ADDITIONAL INFORMATION.

IN answer to our request, which see on page 586, Prof. Cook sends us the following in regard to the crystallized honey-dew:

Yes, friend Root, and you may add my thanks for such a mine of sweet, and that, too, from lice, it is good to see. In every case the source of the honey-dew—lice secretion were more appropriate—is found to be aphides, or plant-lice. Surely our friend need not condemn such nectar. I am sure the honey from Oregon will lose nothing of its reputation if the nectar is always as sweet and wholesome as this.

As you know, Mr. Editor, the great crystallized masses, large as the end of one's finger, were not only very sweet, but were very pleasant. The lice on the fireweed were of the genus *Aphis*, as shown by the long nectar-tubes, or nectaries. Those on the fir were of the genus *Sachnus*. These must have secreted an immense amount of nectar, to show so much cane sugar. It is a good thing for the sugar-manufactories that these lice are not very common, or the former would have to go out of the business. Just to think of a single twig, less than six inches long, having more than a table-spoonful of fine sugar on it, and that all crystallized and refined, with no care or labor! As I have always observed, the sweet secretion of these plant-lice is always pleasant and harmless, and I do not believe it will ever be any detriment to honey. We can not say the same of that from bark or scale lice, for that is bitter and distasteful to bees and to us. I say distasteful to bees, for I have noticed that bees will treat bark-lice nectar as they do glucose,—leave it entirely alone if they can get nectar from any other source. This is not true of aphid nectar, which attracts bees even at the very time that the incomparable basswood and clover secretion, or nectar, is abundant.

As Mr. R. suggests, honey-dew does not fall. So-called honey-dew is almost always secretion from insects. It may come from fungi, as shown last year to be true of the ergot; it may come from extra-floral glands, like those of the cow-pea, illustrated in my *MANUAL*. I think no apology need be spoken for this plant-louse nectar. It will never harm the honey.

MORE NOTES AND COMMENTS.

THE ADVANTAGES OF A PERMANENT HOME.

NOW I do envy those people who can always stay put! I am as fond of a pleasant home, lawn, shrubbery, flowers, trees, fish-ponds, cranberry meadows, grape-tries, and strawberry-patches—well, as the Editor of GLEANINGS himself—which is saying a great deal. But these things are inconsistent with moving about much, and I have had considerable of this to do in the course of my life, especially of late years. Since my last article appeared in GLEANINGS, I have moved once more. Why do the Scotch call a change of residence "flitting"? It is a much slower affair than a "flit." The worst part of moving is getting things to rights, and settling down to regular habits again. During this interval of interruption, several matters have come up in GLEANINGS on which I wish to say something; and as I must try to squeeze them into one article, I adopt a similar heading to my last, and call these *more* "Notes and Comments."

A PLEA IN FAVOR OF WINTERING ON SUMMER STANDS.

I want to speak a good word in behalf of friend Reed, of Milford, Wis., whose letter appeared in GLEANINGS of May 15th. I ordered two of those very cheap stocks of bees advertised by him, and found them, on arrival, exactly as represented by him. Some things in a letter from him touched me very much. He said he had cherished the ambition of getting up a first-class apiary, but had been obliged to give up through ill health. An old complaint had been brought back by the exertion put forth in carrying his bees out of the cellar. This is one argument, and by no means a slight one, in favor of outdoor wintering. In the past, when I practiced cellar wintering, carrying out my hives in spring generally brought on an attack of lumbago, and I never kept more than 20 or 25 stocks. Let us not commend bee-keeping as an occupation suited for invalids or weakly persons until we give up the folly of cellar wintering. Had friend Reed wintered on the summer stands, probably he might have been able to continue his much-loved pursuit. Anyhow, I am sure he has the sympathy of all his fellow bee-keepers, and the prayers of many that his affliction may prove for the best.

CLIPPING QUEENS' WINGS.

By the way, friend Reed has almost converted me to clipping queens' wings, which he practiced. Having to go from home for a few days, June 10th, I carefully searched for queen-cells on the morning of my departure. I was away longer than I expected, and felt pretty anxious about the bees. On returning, my wife said to me, "Some of your bees have had a great fight." I examined the hives, but found no evidence of a fight." Next day, as I was busy writing, my wife said, "Those bees are fighting again." I sallied forth and found the bees not fighting but swarming, out of one of friend Reed's hives. The bees whirled around in the air, but did not alight. So I suspected the queen was not with them, and, on searching, soon found her crawling on the ground. Then I saw what I had not noticed on looking through the hives, that one wing was clipped. I felt pretty cheap; for one argument I have used against clipping is, that it disfigures the queen. However, I picked her up, put her under a tumbler, moved the old hive, set an empty one in

its place, and soon the swarm came back. I ran in the queen, and the whole thing was over in a quarter of the time usually taken in hiving a swarm. I am hard to convert; but undoubtedly I should have lost that swarm if the queen's wing had not been clipped; and now the question is, "to clip or not to clip." One curious thing about the affair is, that the hive is up on a stand two feet above the ground. So on the previous occasion, when they tried to swarm, her majesty must have crawled up one of the legs of the stand, in order to get back into the hive.

HIVES.

GLEANINGS has had a great deal to say about hives of late. Well, I have tried many—so much the worse for my peace and comfort, and I am settling down on some form of Simplicity. The one you make has many excellent features, and the movable bottom-board just suits my hibernation theory. The Heddon style, too, I like; but that lath honey-board seems to operate as somewhat of a barrier to the bees ascending to the honey-boxes. Friend Lake, of Baltimore, makes some hives with valuable features. His No. 2, especially, is a capital hive, convenient to handle, and a good wintering hive. The Falcon hive, made by W. T. Falconer, of Jamestown, N. Y., is the neatest, nicest, and best-finished form of Simplicity I have seen. It has one feature that is especially good in the working season when the hives are overflowing with bees, and that is a removable side. It comes out readily, and is never fastened with propolis, because there is a division-board and chaff-filled frame between the side and the brood-nest. When these are taken out there is plenty of room to manipulate the frames. I suppose we can not get all valuable features combined in any one hive. I wish we could. But can not all makers of Simplicity or Langstroth frames agree on the exact size of frame to be used? I have had more trouble with frames varying just a little in size, than any one thing in my apiary. You want to change frames from hive to hive for various purposes, and it is most provoking to find one a little too long, and another a little too short. The trouble is mainly with the top-bar.

WIRED FRAMES.

Both last season and the present I have tried wired frames. I find that the bees nibble round the wire in some cases, and work away for a good while before they accept the situation, and I can not see that there is any particular need of this wire, for I have just as pretty frames of comb as can be produced, built on foundation simply hung from the top-bars. So far, not a single sheet so hung has fallen. I think, however, that in large apiaries where it is necessary to prepare a lot of hives in winter there might be trouble about this sheet getting loose, for extreme cold seems to make the wax very dry and less adhesive. But, can not some cute inventor give us a frame in halves, which, going together and binding all four edges of the sheet of foundation, will secure straightness and firmness, and render reversible frames entirely unnecessary? I have no inventive faculty or I would try.

EXPRESS COMPANIES.

I got a nucleus the other day from Dr. Tinker, containing a frame of brood, a pound of bees, and one of his Syrio-Albino queens. When I came to open the box I found the brood-comb broken down, many of the bees killed, and among them the queen. The package was admirably put up, and such a dis-

aster as befel it could have been caused only by a fall from the express wagon, or a violent concussion of some kind. There is no excuse for this kind of thing, and it is time a lesson were taught express companies in regard to careful handling of bees. I have had several losses, due to culpable negligence on their part, during my experience as a bee-keeper, but never got any redress. Generally a complaint has drawn out the threat of refusing to convey bees at all. I think somebody will have to enter action for damages, before due care is taken. No one likes to do this. The loss is usually not very large, and the risk of losing costs in an action hinders taking steps for a legal redress. It seems to me that this is one of the directions in which a National League might bring pressure to bear.

WM. F. CLARKE.

Guelph, Ont., Can., July 15, 1885.

In regard to clipping queens' wings, friend C., it turned out very well in your case; but I don't believe a queen *often* comes back, especially where she has to climb up to a hive that stands on legs.—In regard to hives, I have seen so many changes that never "came to stay," that of late I am getting quite backward indeed in regard to adopting any fixture, or any thing that seems to be an improvement, until it has stood the test of use. The Simplicity hive and the chaff hive both seem to settle back to the original plan, about once in so often; that is, things that we at one time thought would be a great improvement are, sooner or later, dropped as too much machinery, or too much bother, and we have left, as before, a plain simple hive without any loose fixtures.—Why, friend C., you yourself give the best reason in the world for having frames wired, but yet you don't seem to see it at all. Had Dr. Tinker had that one frame of brood built on wires as we have them, it would have been almost impossible for even an *express* official to have smashed it up.—A word in regard to express companies. When we first began to ship bees we had troubles from combs breaking down, bees dead, and honey running out of the hive, etc. We brought a bill to the express company, and they paid it. Finally another bill was brought in, amounting to something like \$20.00. They paid that too; but they then declared that hereafter it must be distinctly understood that they are not to be responsible for damages done the bees; that is, they could not stand such losses. They admitted that may be their employees were careless, but they got the best they could, paid good wages, and got along very well with most kinds of merchandise. After studying the matter over a good deal, it occurred to me that there were two sides to this question. One side is, that the express companies ought to employ agents who would handle fragile things carefully. Because they get pay for so doing, it is their business. If we should want to send a basket of eggs by express, or an expensive vase, or a piece of statuary, it is the express companies' business to handle it so carefully that no harm could come. If they did not, they must pay damages. This course of action promised endless quarrels, lawsuits, and other unpleasant things in life. Do you want to know what the other side was that presented itself to me? It was this: Em-

ploy packers so well trained that they could pack a sitting of eggs, an expensive vase, or any thing else, in such a way that it could be tumbled from one end of the room to the other, without injury. It might be a hard matter to do it with the eggs, but with the vase there is no difficulty at all; and, in fact, almost every thing we ship we have learned by experience *can* be so put up that there is very little danger of harm, with such handling as express companies ordinarily give things they carry. We have adopted the latter plan, and we have got along pleasantly with express and railroad companies, and with almost everybody else. Isn't it the better way, to take the world as you find it—that is, within the bounds of reason, and adapt yourself to the world? Of course, there are extremes, such as the following: In loading a half-barrel of honey, one of the railroad employes let it drop. The agent promptly informed me of the circumstances, and asked me to help them out of a bad job, and the money was handed over at once. At another time a cask of beeswax was broken open and a quantity abstracted. The railroad company objected to paying the claim. But their agent, who was a personal friend of mine, wrote to the company something like this: "Mr. Root does a large amount of business with us, as you may know, and I take pleasure in saying that he makes comparatively few complaints. I think his claim ought to be honored." In response to this, the money was handed over at once.—Just one more thought in regard to wired frames. I know the bees do sometimes, when there is a dearth of honey, gnaw the wax away from along the wires; but when put into the hive during a good yield, the wires are very quickly covered and out of sight; and as soon as one set of brood is reared over the wires they are never molested afterward.

WHERE DID THE EGG COME FROM?

DO BEES STEAL EGGS FROM OTHER COLONIES?

THE condition of the colony was such as to preclude the possibility of its containing an undeveloped egg. In the first place, a swarm was thrown off June 12th, and as soon as queen-cells were old enough all but one or two were taken out and used to queen other colonies. On the 25th of June a second swarm was thrown off. The hive was examined, and a young queen removed, and the swarm ran back. On the 29th the queen was still on deck; but a close examination failed to discover any eggs. On the 8th of July no queen could be found, no eggs in the hive, no unsealed brood, and very little sealed, and that was in a comb that had been used in exchange with another hive, the exchange being made about June 20th, to get queen-cells for the other colony.

Now, suppose this comb had been full of eggs (which was not the case, as the colony it came from had been queenless for three or four days), is it at all probable that any egg in it at that time would have remained undeveloped till the 8th of July, at which time the colony was found to be queenless, and had started queen-cells, in one of which was an egg? Not expecting to find any thing in the cell,

which was about half length, I pulled it down, and, to my great surprise, in the bottom I discovered the egg; and while I still held the frame in my hands it was removed. What was done with it I am unable to say, as I gave the colony a hatching queen-cell on the 10th, placing it between the top-bars, not lifting any frame out. Is it unreasonable to suppose, that, while I had frames out of some other hive, an enterprising bee, instead of stealing a load of honey, helped himself to an egg, and carried it home, and caused more rejoicing there than would a whole frame of honey? I think not.

Quincy, Ill., July 16, 1885.

JAMES KNOX.

Friend K., I presume it is possible for worker-bees to steal an egg in the way you suggest, or in some other way, although I can hardly think it is probable. Cases have been mentioned, quite a number of them, where it was at least very hard to explain where the egg came from, unless it was stolen in some such way.

BUILDING UP NUCLEI TO FULL COLONIES IN THE FALL.

EXPERIENCE OF A NOVICE IN THE MATTER.

I AM glad that I am again taking GLEANINGS, having been without it a year and a half. I subscribed for it in 1883, and thought one year would be all that I should probably want it; but not so. The first number, Aug. 15, has been received, and the first article in it is worth the one dollar to me, if you keep it up in the next issues till you give us one good letter—in detail—on building up nuclei to full colonies. That is just the business I am at now. I am willing to put down some of my experience, and let it go for what it is worth; and I should be glad to read reports from others; but I shall not be satisfied till I see an article from a bee-man of experience.

The first week in July I received and commenced feeding a two-frame nucleus with Italian queen, and, I presume, one pound of bees. There was but little brood in the combs. I fed awhile with candy, then put in one frame of foundation, and fed about half a pound of sugar syrup each day. As soon as one frame of fdn. was nearly drawn out and filled with eggs, I inserted another. Soon I fed 1 pound of sugar. The second and third frames of fdn. were drawn out and filled with eggs in less time than the fourth and fifth. It seems to me I did not get as good work from the bees (in comparison) when I was feeding one pound of sugar as when I fed half a pound. I was trying to get the best hive of bees at the least expense. At this date this is a good colony, strong enough to winter all right in Ohio, if it have 25 lbs. of syrup. I tried black bees as above, and they did not draw out the fdn., except just enough to store the syrup in it. It did not pay to feed black bees; but all my Italian nuclei have done well, and are still doing so.

L. W. GRAY.

Troy, Orange Co., Fla., Aug. 26, 1885.

Thank you, friend G., for your kind and approving words. I think you are on the right track, and I should say you are doing quite well. I think your one experiment with the nucleus of black bees was hardly a fair test, for I am sure they can be worked the same way as Italians; but I am also sure that, as a rule, the Italians would far

outstrip them. Twenty-five pounds of sugar, fed at this date, ought to make an excellent colony, with abundance of stores, until fruit-bloom next season.

SOMETHING MORE ON THE SAME SUBJECT.

Please give me a little information in regard to bees. First, I have an opportunity of buying some swarms now, for \$2.00 per hive—the old square box hive. Now, then, I can wait until next May or June, and buy all the young swarms the party has, for \$1.00 per swarm, I furnishing the hive. The party hires the bees and puts them into any kind of a hive I may take to him. Now, Mr. R., I come to you for advice: which must I do? I am a young beginner in the bee business. Shall I buy the old hive, or wait and get the young swarms, putting them in hives that I can handle?

WHITEWASHING HIVES.

Do you think it advisable to whitewash bee-hives? The hives are ready made, but the lumber was never dressed, and is still in the rough. I can also have the Langstroth hive cut out with the lumber dressed, ready to nail together, for only 40 cts. apiece. Is that too much, or is it cheap? J. O. BARNES.

Hickman, Fulton Co., Ky., Aug. 27, 1885.

Why, my young friend, I should think you had a splendid chance to build up an apiary, at a very small expense. If I wanted to build up an apiary, I would take box-hive swarms now at this price, say five or ten, according to my means, and then I should be ready to take all the new swarms that can be bought at a dollar a swarm next year, putting them, of course, into modern hives.—I would not whitewash bee-hives. It looks unsightly, and is but little more protection than nothing. It adds to the appearance for only a little time; and when the whitewash is partly worn off, it seems to me they are far more unsightly than plain wooden hives without any attempt at either paint or whitewash. Whitewash holds better on rough boards than on planed boards, but you can not make a good serviceable hive of unplanned lumber very well. If you can get the stuff in the flat, cut accurately, for 40 cts. apiece, I should say it was very reasonable.

A GOOD-NATURED PROTEST FROM A FRIEND IN ALABAMA.

"FIRST CAST OUT THE BEAM OUT OF THINE OWN EYE."

ON page 566 you tell Bertie Norrell that you are afraid she is a little severe on her neighbors who work in the factory. I agree with you. Although my wife's grandfather was a native of Rhode Island, I know nothing at all of the moral and social status of the "factory folks" of New England, and very little, I admit, of Southern "factory folks," yet I think it hardly charitable to dub either "an illiterate, oily, unwashed class;" for might not some combination of circumstances, such as bereavement, poverty, etc., induce a lady—north or south—who had seen other and better days, to accept factory work as the best employment available, and as being far better than becoming dependent upon others, or allowing herself and family to suffer? I have heard of such cases, and I doubt not their existence.

In regard to snuff-dipping, I think the practice is becoming a thing of the past, though too much of it still exists; and among our colored people the habit prevails extensively. I can not say, of course, how much has fallen under our fair friend's observation; but when she casts a slur upon the good name of Alabama, and the "nicer class of ladies of Central Alabama" in particular, I am *hurt*, and must protest. That is where I *live*, and I have a mother, sisters, and wife, to say nothing of scores of relatives and friends belonging, I suppose, to our friend's "nicer class," who do not now, never did, and never will use tobacco, as snuff or otherwise. There are a few, very few, individual exceptions to be found in this class—usually an old lady who contracted the habit years and years ago, and who has not the fortitude or powers of physical endurance to break it off, and who usually makes no secret of it. Our young Georgia friend has evidently been misinformed, or has enjoyed (?) a very limited observation of us. Supposing, however, that it was all true, and more too, why should she so eloquently hold up to the world the faults and moral deformities of *others*? And you, old friend, had you not better "look out," or you will again feel as you did when writing the foot-note to friend W. F. Clarke's communication on page 376. Now, if the sentiment that prompted that foot-note condemns *this* communication, I'll try to be content. While it does not pertain to bees, I *believe* it will be heartily indorsed by your Southern subscribers, and not objectionable to others. It is simply an effort to right a wrong; and if Central Alabama, my home, had not been particularized, I would not have said a word.

2—J. M. JENKINS, 30—43.

Wetumpka, Ala., Aug. 24, 1885.

Friend J., I humbly beg pardon. I ought not to have allowed that sentence to appear in print; but I did it mainly that I might say a word of caution to the children about uncharitable speaking. I will try to be more careful hereafter. But we can all gather a moral from it as it is; that is, let us try to maintain the good standing of our respective States. Your communication has brought out this fact, which you all remember that I intimated—that tobacco-using among the ladies is mostly confined to those well along in years, and it is just so here in our State. You will remember that I mentioned, some time ago, that when I was obliged to stay a few hours in a strange town, of going from the station on account of the tobacco smoke, then to the dry-goods store; and, finding that worse still, I went to the hotel. As I found no relief there, they were obliged to put me in a room with the women-folks. In a little while I got into a good chat with quite an old lady, on the subject of religion; but before she could express herself to her notion, she was obliged to fish a pipe out of her pocket, and commence smoking. Now for all that, I believe her to be a real true Christian, and one of God's chosen ones. She was brought up in that way, and I would not think of asking her to put away her pipe in her old age, just because of the trifling inconvenience it gave me. We who are young and strong, ought to be ashamed of such things; and I think, too, we can unite in friendship and kindness in deciding to set the best example we know how, even if we

can't do more. May God bless your friends and relatives, friend J., and the inhabitants of your beautiful State of Alabama; for I know a little about it, even if I don't know very much.

CARP CULTURE COMPARED WITH BEE CULTURE.

FACTS ABOUT CARP IN GENERAL.

I THINK every man who has a suitable place should have a carp-pond as well as an apiary; in fact, I believe those who have tried both, find that there is as much profit, if not more, in carp culture than there is in bee culture; or, at least, I find such to be my experience, for I have made considerably more clear money in carp culture than in bee culture, though I am an A B C scholar in both. I will say, however, that I do not expect to make a specialty of either. I have two ponds. Both together cover about one-fourth of an acre of land. I stocked one of them in February, 1883, with only 28 carp, varying in length from $1\frac{1}{2}$ to four inches. In March, 1884, I drew down my water and found only 20 of them, being in length from ten to fourteen inches. The others, I presume, had been destroyed by mud-turtles, some of which I caught.

I sold eight carp to a neighbor, and two more afterward got destroyed, leaving only ten. I succeeded in raising about 150, which spawned about the middle of May last (they having spawned only one time during the season), which were from four to six inches long when I transferred them to my other pond, to stock it. I am confident that I had many more hatched out than were raised, for I could see them swimming on the top of the water in considerable numbers when they were about an inch long. I think that the frogs must have destroyed them, as they were very numerous about the pond. I intend making my ponds frog and turtle proof by setting posts all around, and planking to the posts, letting the bottom plank into the ground, and making close joints, until I raise it $3\frac{1}{2}$ or 4 feet high.

My ponds are ditched, or drained all round, to avoid being overflowed by hard rains. Ponds should be constructed, if possible, so as to have part of the bottom of mud or soft loamy earth; for in freezing weather the fish partially bury themselves in the mud. The rest of the bottom should be top earth, as it will produce more swamp grass, which the fish eat. In excavated ponds the feed is very nearly all supplied artificially, as but little natural food will spring up in such ponds. The depth of the water need not exceed $3\frac{1}{2}$ or 4 feet in this latitude, and only a small channel need be that deep, and the rest of the bottom should range from one to sixteen inches deep, as more grass will spring up and grow in shallow water; and besides, the sun will warm the water quicker, and the spawn will hatch better, than in deep water; in fact, those who have had experience in the business say that water may be so deep that it is doubtful whether the spawn will ever hatch.

My ten fish that are now in my brood-pond are 18 to 20 inches long, three of which are leather carp, the others scaly ones. They are two years old; some of my neighbors who have some three years old say they are from 24 to 26 inches long, and weigh from 14 to 16 lbs. The scaly carp seem to

have the preference for table use, but I think leather backs outgrow them. My fish will eat almost any kind of food that a hog will, such as cabbage, onion - tops, peaches, mulberries, blackberries, grapes, young tender wheat, oats, boiled corn, raw cow-peas (swelled), bread of all kinds, and, in fact, scraps of almost any thing, and even little pieces of dead forest-leaves, or trash, that floats on the top of the pond.

J. D. BROWN.

Bowman, Ga.

MY REFERENCE BOOK.

THE WAY IN WHICH FRIEND DOOLITTLE CLASSIFIES AND UTILIZES WHAT HE HAS READ AND CONSIDERED.

WHILE reading the bee-papers, it is generally to be noted that nearly all writers tell us about things which are past; this, put with the time it takes the article to get to the publisher, and the same to be placed in our hands through the mails, together with the printing, makes nearly every valuable article which we read a month or more behind the time most appropriate for its use. I am not finding fault with the correspondents of the bee-papers regarding this state of affairs, for it is quite natural that this should be so. There is no time a person feels more like telling what he has done, and how he did it, than just after doing it successfully. There is a certain inspiration on a person at such times which allows of their story being told better than it could possibly be at any other time after several months have passed away, as must always be the case where the story is kept so that it can appear before the public in its appropriate season. Thus it happens that all of the best articles on wintering have appeared in the spring; the best article on securing a large yield of honey after the honey harvest is over, and the same is true of nearly every other subject pertaining to bee culture. Now, our bee-papers are of value to us only in proportion as we remember and put in practice the valuable points they contain; and as my memory is not sufficient to keep track of all that is of value, appearing out of season, I must have some means of reminding me of the valuable points just when they are of use. Again, much of the matter in the bee-papers is of little value to the experienced bee-keeper, except to add a little to the "spice of life" by adding variety to our reading-matter.

There is only now and then an item or an article we wish to look at the second time, so what we want is some plan by which we can get at that which is really valuable when wanted at another time. To do this I struck on this plan: Whenever I sit down to read a fresh paper, I have a pencil with me; and when I find a new idea, or an old one I wish to further experiment with, I mark it. In some instances the marks will embrace a whole article, while others call attention to only a few lines. In future years, or at any time I wish to find that which is really valuable in my store of bee-literature, all I have to do is to read the marked passages, and thus get the cream of a whole year's numbers of GLEANINGS or other papers in a little time. Now, the above would be all that would be necessary, were it not for the matter of most articles being out of season, as spoken of at the beginning of this article, but for this reason I want some arrangement which will cite me to all the valuable points so that I can practice each

in its appropriate season. After further studying on the matter I decided on what I call a "Reference Book," which is simply a small blank book bound in leather. Any memorandum or account-book will answer the purpose, providing it has at least 24 leaves in it. This book I arrange similar to an assessor's book, which has the letters of the alphabet from A to Z on the outside margin of the leaves. Cut the leaves just as you would to letter them; but instead of lettering them, write on the little square of the first, "Jan. 1st;" on the second, "Jan. 15th;" on the third, "Feb. 1st," and so on, giving one leaf, or two pages, for each half-month, to the end of the year. Having the book thus fixed it is kept near the chair which I usually occupy when I read, together with a pencil, so that when I come to any passage, part of an article, or an entire article that I think will be of any service to me, either as something new that promises to be valuable, or some new plan of using something already familiar to me, I mark it with my pencil, and then jot it down in my book, under the date to which it is applicable. Thus I get all the matter which I consider valuable, contained in what I read regarding apiculture, arranged with reference to the time it is to be used, in this book.

When Jan. 1st arrives I look over all there is on this page, and, for instance, try fixing one of my saws so as to make it saw smoothly, as described on page 408 of GLEANINGS, by way of experiment, if I chance to find a note regarding that in this little book. To explain more fully: On page 533 I read how to cut up foundation by using kerosene oil and a butcher-knife, so that thirty or forty sheets can be cut at a time. As I had always used the Carlin wheel, or a stamp cutter like those used by D. A. Jones, for cutting my fdn. starters for sections, I thought this might be better, so the plan was marked. As the first half of May would be the time I would most likely want to use it, I turn to May 1st (by putting my thumb on that date when opening my reference book), and write GLEANINGS, 1885, page 533, "How to cut fdn." When this date (May 1st) arrives I look over all that is written there, and, as I come to this, I turn to page 533, and there is just what I want, at the right time; for in a day or two I must go to work cutting fdn. into starters for my sections. So I go to work and cut a part by the new way, and some by the old. If the new proves the more valuable I mark these words on my reference book with a star; or, if worthless, I draw my pencil across the whole line, thus crossing it off.

If I have made it plain, and I think I have, it will be seen that I have all the real worth of many volumes in this little book, while the matter which was worth only once reading is left out. Different persons would make different selections from what I should; but the plan is a good one, in my opinion, and one which will be of great service to any one who will follow it.

G. M. DOOLITTLE.

Borodino, N. Y., Sept., 1885.

Friend D., your suggestion is an excellent one. It was only the other day that I began to consider that it was almost impossible for me to remember, in time for action, what I had already learned. Somebody comes along and suggests a very decided improvement on what we are doing; and after thanking him for it I remember that I had read the same thing a long time before. but

had forgotten it. Now, your plan, if I understand it, is something like the monthly calendar, found in many books on bee culture, agriculture, etc. As each season comes in turn, you look at your reference book, to see what you had marked down to be done at such a season.

DRONE-EXCLUDERS.

Do we Want our Drones Caged Up, or do we Simply Want to Drive them Away?

FRIEND ALLEY CRITICISES THE SPAFFORD DRONE-EXCLUDER SOMEWHAT.

MR. SPAFFORD has described and illustrated a drone-excluder which he calls "better than Alley's." The arrangement as shown and described will no doubt work "like a charm"—a fact I discovered more than 25 years ago. The same device described by Mr. Spafford was exactly what I used in connection with my first drone-trap. But I did not only exclude the drones from the hive, but I caged all in a box as they came out to take a flight. From this came my drone and queen trap. Now, if friend Spafford will place a box at the end of the outlet of his excluder he will have the principle of my drone-trap complete. I do not use drone-excluders, and never did in my apiary. They are as useless a piece of furniture in the apiary as one can have. Of what benefit is it to exclude drones from a colony of bees? They return to enter the hive again when they have had a flight. If they can not enter some hive, they will block the entrance and interfere with the working bees. Unless excluders are placed at the entrance of each hive, the drones will soon find a home in some colony in the yard. When it can be done as well as not, why not exclude the drones and at the same time catch and destroy them? Every drone can be entrapped and destroyed with very little trouble to the apiarist; and by the use of the same device his bees can not swarm and abscond.

When I used the device as described by Mr. Spafford, I found the bees would soon gnaw the wood away, and the drones had no trouble in getting into the hive again. I used tin to prevent this, but it was a very unreliable way to manage and control drones in an apiary. As I have before stated, my drone-trap was not perfect until I obtained perforated zinc. As these traps are now constructed, every drone can be destroyed. Those we have made this season have shorter tubes through which the bees pass into the trap. I noticed, when watching the working of the traps, that some of the drones would get half way up the tube; the distance was so great that they would turn about and go back. I soon remedied this slight defect. Then, again, instead of nailing the zinc on the front of the trap, or letting it run in on grooves, I now cut the zinc so that it goes inside the ends of the trap, and the bottom edge runs about half way back toward the hive, thus forming an inclined plane over which the drones pass directly into the tube, and into the trap. As now made, I believe the trap is as perfect as it is possible to make them.

I do not see how any man can claim that the excluder of Mr. Spafford's is better than the one described by me in GLEANINGS some two years ago. The latter was exactly like Spafford's in principle,

and as it is so arranged that there is a chamber back of a piece of perforated zinc, it afforded plenty of ventilation to the hive. Let some one apply Spafford's drone-excluder to a strong colony during a hot day, and see what the effect will be. The colony can not possibly get proper ventilation by such an arrangement. This is not theory. I know from 25 years' experience what I am talking about.

Wenham, Mass., Aug. 25, 1885. HENRY ALLEY.

Thanks for your hints, friend A. With the years of experience you have had in this matter of getting rid of drones, no doubt you are right, in the main; but for all that, I think the Spafford implement will answer a very good purpose under many circumstances.

PREPARING THE BEES FOR THE HONEY SEASON.

HOW I HAVE WORKED AND SUCCEEDED.

THE outlook for me this last April was splendid. My bees had wintered so well, comparatively (and I had learned, no matter how, how to make them build up in the spring) that I was just going to have my hives roaring with bees when white-clover harvest set in. I was not in the hurry I once was, to remove the winter packing. In some cases I put a frame outside of the division-board; in others I merely uncapped some of the honey occasionally, adding frames of stores as the latter became scarce. I had so many extra frames with more or less honey in them that I did not feed any syrup. I commenced by turning each alternate frame containing brood, end for end. As the bees begin rearing only at the front half of the frames, by this means the two or three frames containing brood would soon be full. Then I would spread the brood, inserting the frame containing none in between.

The above methods, I believe, stimulate brood-rearing as well as any kind of feeding. The area of brood increased so rapidly that early in May I began to remove a division-board in one side, and insert another frame. The methods pursued which, to me, were something of a trial, were succeeding admirably—at least, so it seemed for awhile. But now when clover is beginning to blossom, what is the final result? I am no better prepared for the harvest than I have ever been before. I might almost say that my hives are full of brood and empty of bees. I have not a dozen first-class stocks on the place, while there are no more bees in my 45 hives than there should be in 30. Do not tell me, please, that I have made some prodigious blunders. I think I know where I made some mistakes. The spring has been cold and backward. The different fruits bloomed about a week later than usual. Next spring, however, may be entirely different, and my plan may work well as pursued this season. After all, then, what have I proved? Neither that to stimulate brood-rearing in the spring *will* or *will not* build up. With two or three exceptions my bees showed but slight traces of dysentery, so they could not have been weakened from that cause.

Mechanicsburg, Ill. GEO. F. ROBBINS, 39—15.

I should say, friend R., that your spreading and changing ends with the brood did more harm in the end than it did good. May be if you had waited until the season was a little further along, however, it might have turned out differently.

He that is faithful in that which is least, is faithful also in much. — LUKE 16:10.

MYSELF AND MY NEIGHBORS.

And Abram said unto Lot, Let there be no strife, I pray thee, between me and thee, and between my herdmen and thy herdmen; for we be brethren.

— GEN. 13:8.

I BELIEVE I have told you something about our honey-wagon that we send around our town every day. Our population is only somewhere about 2000, so that by taking one-half of the town one day, and the other half the next, we go to almost every house every two days. Well, while we are carrying honey around to the houses, we could just as well take something else; and as market gardening is a sort of kindred industry, we have been taking celery, summer squashes, melons, cucumbers, and lettuce, besides fruits, such as apples, pears, peaches, huckleberries, etc. The undertaking was rather a novelty in our town, and it first occasioned considerable remark. Many prophesied that it would not pay expenses, etc. I rather thought it would pay expenses in time, because it is a convenience and saving of time to the people of a town of this size, to have such things delivered right at their doors. It saves them carrying heavy market baskets; it gives them the products of the soil fresh from the ground, and they can see the things before buying, and can buy or not, as they choose. The opposition that at first arose soon gave away, as I expected it would, and eventually the market wagon began to be regarded as a convenience instead of an innovation.

Many of my new enterprises oftentimes make me feel badly before I get them thoroughly established, because they sometimes interfere more or less with other people's business. But this field I regarded as almost unoccupied; and I have for ten years

past felt a longing to open such an industry in our town, because it seemed to need it badly. During the past winter our grocers received from Cleveland many barrels of lettuce, which was sold for as much as 25 cents per pound in winter. Considerable quantities of other early garden stuff were daily brought in by express, during the latter part of winter and early spring. Think of the idea, of an agricultural people sending to the great cities for garden stuff which they could easily raise at their doors, with the aid of a little greenhouse, a few cold frames, and things of that sort! Well, I thought this time I had got a field that was so nearly unoccupied it would harm no one. I found out my mistake, however; for one Saturday evening an old neighbor, whom I had known for years, and who had been most of that time a particular friend of mine, came to see me. I saw by his looks that something was amiss, but could not think what it was, until he commenced as follows:

"Mr. Root, I want you to give me and my boys something to do."

"Why, my good friend, we have nothing for our regular hands to do scarcely; and to keep them busy until another season opens for bee-supplies, we have been making garden, and doing almost every thing we could find to do."

"Well, then I think I had better start a saloon, for a man must do something for a living."

"But, neighbor —, why do you come to me with this announcement? Why am I under obligation to furnish you and your boys work?"

"Well, Mr. Root, it seems to me it is plain enough why you are to blame, when things have got to such a pass that you load up a

wagon full of garden stuff, and send three men around the little town of Medina to peddle it out."

It was all plain enough to me then; and for the first time I remembered that the neighbor before me had for many years been a gardener. His work was principally in vegetables and flowers, however. I remonstrated; but he was somewhat excited, and very positive in his view of the matter. It was true, that we had, during this day, sent out two men, and a boy to drive, for we had quite a quantity of stuff on hand; and as the next day was Sunday, we made a trip both in the forenoon and afternoon. He declared he would have to start a saloon to support his family, unless I stopped that obnoxious wagon. I told him I would think the matter over, and I thought we could arrange it some way so we could get along in a pleasant and neighborly way, as we always had done. But the more I thought of it, the more difficult it seemed to me to avoid striking his old customers, unless I stopped the wagon. But if I did this, how should I dispose of my crops that were just beginning to be ready for market? I hadn't considered the matter very long before I thought of the text at the head of our talk to-day. Of course, he threw it up to me that I professed to be a Christian; and he asked me if it was a Christian thing to do, to break down a poor man's occupation, especially if he had established a business, and earned a livelihood in it for more than fourteen years. He said that he understood that I kept four or five men employed on only ten acres of ground; that I had planted about 8000 stalks of celery, for a little home market like ours. I was obliged to smile in spite of myself when I plead guilty. Yes, and I had to admit it, that the celery-plants were growing splendidly.

I want to digress here enough to say that my friend W. J. Green, from the Ohio Agricultural College, Columbus, has just paid me a visit to-day, and looked at my celery and other plants. There was no celery at the Ohio State Fair equal to ours, neither was there any to be found on the market in the entire city of Columbus, to compare with it; and as my friend took leave he made the remark, "Mr. Root, I think you ought to send a few stalks of that White-Plume celery to Peter Henderson. It might astonish him, even if he is the originator of the variety."

My plans were beginning to bud and blossom, and there had been a pleasant prospect before me for some time of being able to teach our Medina people what could be done in the way of scientific market gardening. But here were my fond hopes, dashed to the ground. It is true, my old neighbor did not do very much at the business, for he never owned even a horse, but did all his work by hand—hiring, perhaps, a man to plow occasionally; therefore the amount of stuff he raised during a season did not amount to very much. But notwithstanding, his little home and his little business were, without any question, in great jeopardy, if I kept on in the way I had been doing. After he had got to talking more coolly, he declared I could not have more effectually broken him

up, had I sat down and planned it out deliberately. Why not buy him out, together with his good will of the business? Several objections met me; first, I might have to buy out every man who owned a little garden. Next he would want me to give him employment. But he drank beer and cider, as many of his countrymen do, and he was in the habit of taking God's name in vain, as I had abundant evidence from his talk then and there. I pondered the question over Sunday. I read that chapter, the 13th of Genesis, and I remembered how Abraham did. It was not an easy matter for me to go away from Medina to start business somewhere else. I stated the question to one of the deacons of our church. He said he thought the claim was a little unreasonable, and that I had a perfect right to go into any such business if I should so choose. But he agreed with me, notwithstanding, that one ought to follow Paul's advice in living "peaceably with all men, so far as in him lieth."

Monday morning, as soon as my work was a little bit ahead, I called on my old neighbor. His wife was sick, and near to death. He was obliged to do his own housework. His boys used to be in my Sunday-school class, but I now remembered that they had not been for some time. As I looked about his garden my heart was touched, and I resolved that, if it were a possible thing, my business should not stand in the way of his business. He seemed sad, but much pleasanter and kinder than he had been the Saturday night before. By the way, dear friends, did you never realize, when you are in difficulty with a neighbor, that it is an excellent thing to see how far you can narrow down your differences until you get at the *exact point of disagreement*? I proposed that we should divide up the garden crops, and that he should raise one thing and I another. I had a great lot of tomatoes, and he had none; he had a large lot of beets, but mine were all sold for the season. So we took up one thing after another, and, to my great joy and surprise, it narrowed down to almost one single vegetable. He had about a thousand celery-plants, and I had eight thousand. Now, said I,—

"Friend —, what will you take for your thousand celery-plants?"

"Why, Mr. Root," said he, "you have eight thousand already, and I am afraid you will not be able to sell them. You certainly do not want to buy any more."

But I assured him that I did want to buy more, and that if he would set a price I thought we could soon make a bargain.

"But, Mr. Root, you are doing this because you want to accommodate me, and not because you want the plants. I feel differently about the matter from what I did, and I guess it is all right. You just go on with your wagon, and we won't say any thing more about it."

"But, how about the saloon? You will not start any saloon, neighbor —?"

"No, I will not start any saloon;" and he smiled in such a good-hearted way that I knew there was no danger. Do I need tell you, friends, what a feeling of joy and peace

came into my heart, not because the way was open to me to go on with my experimental farm of ten acres, but because one more of the Bible texts and promises had been tested and tried. The spirit that Christ enjoins had come out once more triumphant.

The wagon came along a few minutes later, and he looked pleasantly toward the boys who had it in charge. As I rode along home with them I told them how it had turned out.

"Now, boys," said I, "don't ever any of you say a word disparagingly of neighbor—or of his products. If his boys are selling things to any of our customers, let them have the trade, and don't call there; and buy their stuff of them whenever they have any thing that you need, even if you sell it without any profit."

Oh, what a very, very pleasant thing it is to lend assistance to a neighbor who is in the same business as yourself, and to let him see that you are glad to help him, and glad to see him prosper! Why, it is worth more than all the profitable ventures any man ever made! There is one thing I am feeling a little badly about; and that is, that no opportunity has presented itself as yet for me to show my gratitude to my neighbor for the kind way in which he has given way in this matter of competition. I have prayed for him and for his motherless boys, for the mother is now, while I write, no more. But such a multitude of cares press upon me, especially since my absence of three days at the State Fair, that many a thing I had planned to do has to be passed by, as out of the question; but yet, amid all these cares a bright gleam of sunshine seems to break forth whenever I think of those words of that old patriarch when he said, "Let there be no strife, I pray thee, between me and thee, . . . for we be brethren." In my case, it is not exactly brethren by ties of blood, but it is an old neighbor; and what term comes nearer to the title of "brethren" than the one of "neighbor"? How very, very pleasant it is to be able to say, "Nothing but love and kindness exists, so far as I know, between myself and my neighbors!"

A LETTER FROM W. Z. HUTCHINSON.

SHALL OUR CHILDREN HAVE HAMMERS AND NAILS
TO LOSE AND WASTE?

FRIEND ROOT:—If you are busy now, don't stop to read this letter. It isn't a business letter; it is only, as our little girls say, "Just a 'jibber jabber' letter." Put it in your pocket, and read it at your leisure, or to Mrs. R. this evening.

I was much pleased at what you said in reply to one of the juvenile letters; i. e., let the little boy use the nails; they are not wasted. Perhaps these are not the exact words used, but that is the meaning. It carried me back to my boyhood days when nails were so hard to get. Just above our place, on the Butternut Creek, was a saw-mill, and a great many pieces of boards floated down the stream and lodged against logs. From this "flood-wood" we, brother and I, used to pull out pieces of boards,

"edgings" and the like, let them dry upon the bank, and then drag them home to "make things," to build dams, make water-wheels, wind-mills, sawing-machines, etc. But, oh the struggle for nails! Every old board and building was ransacked for them; and if we didn't "find" enough, and took some of father's, then how he would "scold."

I remember one time when brother and I had carried some butter and eggs to a store about five miles distant, and exchanged them for groceries, and some tobacco for father, I bought two pounds of nails, paying for them out of the butter and eggs, and hid them in a log-heap when we got home. But after we had gotten them in this way we couldn't take any comfort in using them, and finally went and told mother all about it. After that she quite often used to let us have a dozen eggs "to buy nails with." I have not yet forgotten how firmly I resolved, if ever I had any children, they should have all the nails they wanted.

Father was a pretty good father, but seldom took much interest in our boyish plans and projects. He had a chest of tools, and allowed us free access to them, for which we have always been thankful.

Well, at last I have children of my own, and they use ten nails where I used one, even if they are girls. In the shop are two large boxes in which are thrown all the odds and ends, and the girls understand that they can have any thing they find in those boxes. If they want any thing else they always come with a "Pa, can I have this?" They are at liberty to use the hammers, nails, and saw; and so proficient have they become, that when I hear them sawing or pounding I sometimes think it is somebody else, and go over to see who it is. Their latest production is a little bee-hive, about eight inches long, fashioned after the Heddon hive. They "got stuck" on the frames, couldn't make them, and felt so badly over it that I came to the rescue; and when the hive was finished, then they wanted some bees in it, and teased so much about it that finally I transferred a nucleus to it. The nucleus had a laying queen. The bees were some of those gentle Italians from Cyula Linswik, and the little girls go down and open the hive several times a day and "find the queen," sometimes without smoke, and sometimes they light the smoker and use it so that can be doing "just as pa does."

How ownership does awaken interest in any thing, doesn't it, friend R.? I thought the girls had asked me about all the questions about bees that they could think of; but when they became the happy possessors of a little colony of their own, when they could take their little chairs and sit down by it and see their bees going out and in the hive, then the questions came thicker and faster. I got along very well until this one came: "Pa, what shall we do with them so they won't die next winter?" I said, "I am going to feed mine sugar, and put them in a warm cellar." They guessed they "would too." The twins are seven this fall, and Ivy is nineteen months younger.

What a pleasure it is to give pleasure, and especially so to give pleasure to those we love! I wonder if parents realize how much they might add to their children's happiness by taking a little interest in their childish pleasures.

I don't know, old friend, why I have written like this to you. I just "felt like it," and that's all there is to it.

W. Z. HUTCHINSON.

Rogersville, Mich.

Well, I suspect, friend W. Z., you just felt like writing as you did, because you knew it would hit me exactly. Huber has arrived at the age of nails and hammers, or pretty nearly so. Only yesterday I scowled up my face, and was going to remonstrate pretty earnestly at the awful clatter somebody was making while I was trying to talk; but after I got where the sounds came from I found it was Huber with a three-cent hammer, a tin dish of nails, and a lot of sticks such as the girls have to put in the A B C book to keep the edges from getting injured in the mails. His face was so full of enthusiasm, and he was having such a real good time, that I let the scowl on my face slide off, and I turned around and went away, and didn't scold a bit. Yes, let even the girls have their nails and their hammers and bee-hives, and whatever else they take a notion to, that will not do them harm, and especially these things that will teach them to love rural pursuits and God's own handiwork. Yes, I remember when I wanted to make a corn-planter, when I was a small boy, my father objected; but I told him if it did not work I would take every nail out, without bending it, and bring them all back to him. I did it, too, and I think it taught me a useful lesson, to remember that nails cost money.

LETTER FROM ONE OF OUR JUVENILES AFTER SHE HAS GROWN UP.

FROM 25 TO 63, AND OVER 1250 LBS. OF HONEY.

FATHER came through the winter with 25 stands. They began swarming the 25th of April, and they just kept swarming until, after all he has said against the old plan, he was compelled to hive in boxes, half-barrels, or any thing. He is a nurseryman, and while attending to his trees, building the new house, and such little jobs, he hadn't much time to look after the industrious pets. They increased to 63, and he has taken only about 50 lbs. to the hive, and left them plenty for winter. The honey is good, well flavored, and thick; but the little scamps have put in a spot of bee-bread every once in a while in the most of it.

I have just been watching the bees dig the "trifolium" off the sides of an empty hive. They carry it away in their leg baskets. I suppose they want it to chink up cracks with. Father has killed some loaded specimens for me, but I suppose they will not reach you in very good shape. There were all kinds at the work—Holy-Lands, blacks, and hybrids.

ALSIKE CLOVER.

Father has some alsike clover. He makes hay of it, and likes it better than any other clover. Several of the neighbors have sown test pieces of it, and, so far as I can learn, they are well satisfied with it.

When I "chipped in" once you mistook me for a juvenile. I am one of those care-free, independent "old maids;" and as I signed only my initials, several who wanted to learn something about Oregon wrote to me and addressed me as "A. M. Hall, Esq.," and "dear sir." I enjoyed the joke very much, but still I thought it was a little rough on the innocent inquirers, and so I shall give my proper name this time.

ANNA M. HALL.

Beaverton, Oregon, August 31, 1885.

Thank you, friend Anna, for your kind re-

port. The spots of bee-bread you say you saw through your comb honey are very unusual, and I should think likely it was caused by something in the arrangement of the surplus boxes in regard to the brood-nest. I have often noticed the bees carrying their propolis in the same way they do their pollen, and I believe you are right in your conjecture that they wanted it to chink up with in anticipation of winter. The specimen you mailed showed the gum still adhering to the little leg.—I believe that some of the best friends I have in the world, Anna, belong to the class which you are pleased to say you represent. You see, women who do not get married always want something to do. I happen to be one of those individuals who always have lots of schemes and plans, and so I am always needing skillful helpers. Well, women who are free from the care of families are just the ones to help me. I help them, and they help me. Isn't that a pleasant relationship?

MRS. CHADDOCK'S LETTER.

She Proposes Starting a Class in Botany Among the Juveniles.

LESSON I.—THE PUMPKIN.

I WANT to study botany; and as it is such lonesome work studying any thing alone, I wonder if the juvenile readers won't help me. Let's begin with the pumpkin. How many of the little folks can tell me to what family it belongs? and who will tell me about the two kinds of flowers found on the same vine? Describe the stamens in each, and tell me where the pistil is. This is a short lesson, but I believe in short lessons and quick answers.

MAHALA B. CHADDOCK.

Vermont, Ill., Aug. 20, 1885.

Mrs. C., I do not know very much about the botanical character of the pumpkin, but I do know this: That Italian bees seem exceedingly fond of the large squash and pumpkin blossoms. The other morning, when I was picking green corn I bumped one of these great posies with my rubber boot (for it was a dark and wet morning), and out came so many Italian bees, one after the other, that I almost began to think they had started a nucleus there. Some years ago a field of pumpkins near our apiary yielded honey enough to settle the hive on the spring scale a little every morning, when the weather was favorable. The trouble about our juvenile class, I fear, will be this: There will not be room enough for a tenth part of the answers.

HOW TO CATCH BUMBLE-BEES.

A NOVEL PLAN.

I WILL write a letter for the juveniles. Under one of my strongest colonies of bees was a nest of bumble-bees, which annoyed me very much. Whenever I went to pull the grass about the hive, out they would come, and smoke would do no good; they would follow me all over the apiary. Yesterday one stung me on the head, and how to get them destroyed I could not think. If I moved the hive I was afraid I should destroy too many bees. My daughter told me to "jug them," and I did.

I took a jug, and filled it about half full of water, and set it by the side of the hive, took a long stick, punched under the hive, and in fifteen minutes they were safely juggled. I think the happiest sight to me that I ever saw was those bumble-bees going "thud" into that jug.

R. ROBINSON.

Laclede, Fayette Co., Ill.

Friend R., I have heard before of setting a black jug near to a bumble-bees' nest, in the way you have described. I never had much faith in it, because it seemed so unreasonable. If it is really true, however, that the bumble-bees will, the whole of them, one after the other, duck down into that black hole, it may be, perhaps, the easiest way of getting rid of such intruders.

THE WAVE OF SKEPTICISM.

BY HARTIE MEACHAM.

A gallant ship was riding,
A ship long tried and true,
Upon the heaving bosom
Of the ocean broad and blue.
And as it glided onward,
A song rose loud and clear,
Whose every note was brimful
Of kindly love and cheer.

At peace were all its workers,
As was the briny deep,
When in the hazy distance
A wave was seen to leap.

At first a tiny wavelet
Was all that could be seen;
But as it rolled onward,
Fast grew its silv'ry sheen.

And as the captain viewed it
With trusty glass in hand,
He said, "Of all the wonders
I've seen on sea or land,

This wave so lone, so frightful,
In its march across the sea,
Is stranger of all wonders
That e'er were shown to me."

Then as onward still it came,
He cried in tones of might,
"Let every man unto the ship
Lash himself so fast and tight.

That the wildly raging wave
Do not wash him overboard,
Faster came the rising swell,
And louder still it roared.

Some hastened to obey his word;
But some of the goodly crew
Said: "Who's afraid of waves-
lets,
On this ship so strong and true?"

Some clung unto the rigging,
And thought by their own might
To resist its wild fury
And be victor in the fight.

Oh, the wail of the lost ones
As it struck that ship so brave,
And dragged the unsecured ones
Down to a watery grave!

Then those poor deluded ones
Who clung by their own strength—
Methinks I hear their shriek-
ing
As they each gave out at length.

And dropped into the waters
Of that seething, surging mass,
For strength and courage
Praying
When 'twas too late, alas!

And as the wave proceeded
Upon its cruel way,
And left the ship uninjured
By its great watery fray,

[Thy word is true from the beginning; and every one of thy righteous judgments endureth for ever.]—Ps. 119:160.

[Thy statutes have been my songs in the house of my pilgrimage.]—Ps. 119:54.

[Great peace have they that love thy law.]—Ps. 119:165.
[My peace I leave with you.]—John 14:27.

[A prudent man foreseeth the evil and hideth himself.]—Prov. 10:12.

[And then appeared another wonder in heaven, and behold a great red dragon having seven heads and ten horns, and seven crowns upon his heads.]—Rev. 12:3.

And all the world wondered after the beast, and they worshipped the dragon which gave power unto the beast; and there was given unto him a month, speaking great things and blasphemies, and power was given unto him to continue forty and two months.]—Rev. 13:4, 5.

[That we be no more . . . carried about by every wind of doctrine, by the sleight of men, and cunning craftiness, whereby they lie in wait to deceive.]—Eph. 4:14.

Therefore, my brethren dearly beloved and longed for, my joy and crown, so stand fast in the Lord, my dearly beloved.]—Phil. 4:1.

[Take heed, brethren, lest there be in any of you an evil heart of unbelief, in departing from the living God. But (short one another daily, while it is called To-day.)]—Hebrews 3:12.

[O God the Lord, the strength of my salvation, thou hast covered my head in the day of battle.]—Ps. 147:7.

[There shall be weeping, and gnashing of teeth.]—Matt. 24:51.

[Let him that thinketh he standeth take heed lest he fall.]—1 Cor. 10:12.

[They that were ready went in with him to the marriage, and the door was shut.]—Matt. 25:10.

[The gates of hell shall not prevail against it.]—Matt. 16:18.

There rose upon the waters
A shout of thanks profound,
From those who, by the orders,
Were so securely bound.

Let us all prepare ourselves
For this wave of unbelief,
That o'er our land is sweeping.
Bringing many hearts to grief.

For 'twill pass upon its way,
And leave our ship unharmed;
But hard's the fate of those
Who'll not
By this sad tale be warned.

Mogadore, O., June, 1885.

[Blessing, and honor, and glory, and power, be unto him that sitteth upon the throne.]—Rev. 5:13.

[But the fearful and unbelieving shall have their part in the lake that burneth with fire and brimstone, which is the second death.]—Rev. 21:8.

[Blessed are they that do his commandments.]—Rev. 22:14.

A JUVENILE'S EXPERIENCE IN RAISING QUEENS.

SOME QUERIES ABOUT IT.

I AM trying to raise queens. I got four nuclei of you at two different times, and have them all in working order now. About a month and a half ago I gave my nuclei some eggs from an Italian queen that produces good three-banded workers. The nucleus drew out some cells; and when they hatched, some of the queens were light and some were dark. About twelve or fifteen days ago I gave them some more eggs from the same, and I now have one virgin queen one or two days old, and she is as black as any black queen could be. There was a swarm came from her mother's hive, and the queen in it is a bright yellow. Now, Mr. Root, can you tell me the reason that the mother is yellow, and her eggs produce yellow workers but black queens?

One of papa's Italian hives sent out two swarms, and after that we thought it was queenless; so we gave them brood to test them, and so, sure enough, they went right to work making cells. After they had sealed them all over, papa cut them all out except one which he left for the queen to rear down. He then caged a virgin queen and put her in the hive and left her there. The cage had some candy in one end, and they ate her out. When I went there the next day they were balling her a little, but I gave them a smoking and left her. The next time I went there I could not find the queen, but found, instead, a cell sealed, which I think was a fertile worker. When papa came home he tore down the cell and hung a laying queen down in their combs, and left her there from Saturday till Monday morning. Then he took the plug out and was going to tie a paper over the cage, when the queen got out and flew away, but soon came back, but flew away the second time, and then we caught her and put paper over the cage. The next day the paper was gone; the queen was gone, but they had a cell instead, which I tore down. Now, Mr. Root, would you please tell me what you would have done with that hive?

IRVING D. BANKS.

Princeton, N. J., August 12, 1885.

Friend Irving, it is quite a common thing to find Italian queens producing full-blood Italians, but whose daughters are very dark. It is common for the same queen to produce dark queens early in the season, or when the cells are reared in small nuclei, while during the summer time her queens will be large and yellow—that is, providing they are reared in good strong colonies.—There is nothing else to do with the hive you mention, but to give them some more brood, to be sure they are queenless; and when you

see cells started, introduce another queen, or let them raise one. Sometimes it takes so long to get a certain queen introduced into a certain colony, that one is sorely tempted to let them perish; but that will never pay, you know.

FESSLER'S BEES.

BY JAMES WHITCOMBE RILEY.

"Talkin' 'bout yer bees," says Ike,
 "Speakin' slow and serious-like,
 "D'ever tell you 'bout old 'Bee'—
 "Old 'Bee' Fessler?" Ike says he:
 "Might call him a bee expert,
 When it come to handlin' bees—
 Roll the sleeves up of his shirt
 And wade in amongst the trees
 Where a swarm 'ud settle, and—
 Blamedest man on top o' dirt!—
 Rake 'em with his naked hand
 Right back in the hive agin—
 Jes' as easy as you please!
 Nary bee 'at split the breeze
 Ever jabbed a stinger in
 Old 'Bee' Fessler—jes' in fun,
 Er in airnest—nary one!—
 Couldn't agg one on to nuther,
 A-y one way er the other!"

"Old 'Bee' Fessler," Ike says he,
 "Made a spesbyalty
 Jes' o' bees, and built a shed;
 Len'th about a half a mild!
 Had about a thousan' head
 O' hives, I reckon—tame and wild!
 Durndest buzzin' ever wuz!
 Wuss'n telegraph poles does
 When they're sockin' home the news
 Tight as they kin let 'er loose!—
 Visitors rap out and come
 Clean from town to hear 'em hum,
 And stop at the kivered bridge;
 But wuz some 'ud cross the ridge
 Allus, and go closter—so's
 They could see 'em hum, I s'pose!
 'Peared like strangers down that track
 Allus met folks comin' back
 Lookin' extra fat and hearty
 Fer a city picnic party!"

"Fore he went to Floridy,
 "Old 'Bee' Fessler," Ike says he,—
 "Old 'Bee' Fessler couldn't bide
 Children on his place," says Ike.
 "Yit for all they'd climb inside
 And tromp round there, keenerlike,
 In their bare feet. 'Bee' could tell
 Ev'ry town boy by his yell—
 So's 'at when they bounded the fence
 Didn't make no difference!
 He'd jes' git down on one knee
 In the grass and pat the bee;
 And, ef 't adn't staid stuck in,
 Fess 'ud set the sting agin—
 'N potter off, and wait around
 Fer the old familiar sound.
 Allus boys there, more or less,
 Skootin' round the premises!
 When the buckwheat was in bloom,
 Lawdy! how them bees 'ud boom
 Round the boys 'at crossed that way
 Fer the creek on Saturday!
 Never seemed to me su'prisin'
 'At the sting of bees 'us pizin'."

"Fore he went to Floridy,"
 Ike says, "nothin' 'bout a bee
 'At old Fessler didn't know—
 W'y, it jes' 'peared like 'at he
 Knewed their language, high and low!
 Claimed he told jes' by their buzz
 What they wuzt and wishes wuz!
 Peek in them-air little holes
 Round the porches of the hive—
 Drat thespesky little souls!—
 Could a skinned man alive!
 Bore right in there with his thumb,
 And equat down and scrape the gum
 Outen ev'ry hole, and blow
 'N bresh the crumbs off, don't you know!
 Take the roof off, and slide back
 Them-air glass concerns they pack

Full o' honey, and jes' lean
 'N grabble 'mongst 'em for the queen!
 Fetch her out and show you to her—
 Jes', you might say, interview her!"

"Year er two," says Ike says he,
 "Fore he went to Floridy,
 Fessler struck the theory
 Honey was the same as love.—
 You could make it day and night.—
 Said them bees o' his could be
 Got jes' twic' the work out of
 Ef a feller managed right.
 He contended ef bees found
 Blossoms all the year around,
 He could git 'em down at once
 To work all the winter months
 Same as summer. So one fall
 When their summer's work was done,
 'Bee' turns in and robs 'em all—
 Loads the hives then, one by one,
 On the cyars, and 'lowed he'd see
 Ef bees loated in Floridy!
 Said he bet he'd know the reason
 Ef his didn't work that season!"

"And," says Ike, "it's jes," says he,
 "Like old Fessler says to me,—
 'Any man kin fool a bee,
 Git him down in Floridy!'
 'Peared at fust, as old 'Bee' said,
 Fer to kind o' turn their head
 For a spell—but bless you! they
 Didn't lose a half a day
 Altogether!—Jes' lit in
 Them-air tropics, and them-air
 Cacktusses a-ripen-nin,
 'N magnoliers, and sweet peas,
 'N 'simmon and pineapple trees,
 'N ripe bananners, here and there,
 'N dates a-danglin' in the breeze,
 'N figs and reezins ev'rywhere—
 All waitin' jes' fer Fessler's bees!
 'N Fessler's bees, with gaumy wings,
 A-gittin' down and whoopin' things!
 Fessler kind o' overseen!"

"Em, and sort o' 'hee-o' heein'!"

"Fess, of course, he took his ease,
 But 'twuz bilious on the bees!
 Sweat, you know, 'ud just stand out
 On their forreds—pant and groan
 And grunt round and limp about!—
 And old 'Bee,' o' course, a-knowin',
 'Twuzn't no fair shak to play
 On them pore dumb inseccks, ner
 To abuse 'em that away.
 Bees has rights, I'm here to say,
 And that's all they ast him fer!
 Cleared big money! Well, I guess
 'Bee' shipped honey, more or less,
 Into ev'ry State, perhaps,
 Ever put down on the maps!"

"But by the time he fetched 'em back
 In the spring agin," says Ike,
 They was actin' s'picious like.—
 Though they 'peared to 'lost the track
 O' every thing they saw or heard.
 They'd lay round the porch and gap'
 At their shadders in the sun,
 Do less like untill some bird
 Suddenly 'ud may be drape
 In a bloomin' churry-tree,
 Twitterin' a tune 'at run
 In their minds familiarly:
 They'd revive up, kind o', then,
 Like they arried,—"Well, it's ben
 The most longest summer we
 Ever saw or want to see!—
 Must be right, though, er old 'Bee'
 'Ud notify us," they-says-ee,
 And they'd sort o' square their chin
 And git down to work agin—
 Meanin' round their honey makin'
 Kind o' like their head was achin'.
 Tetchin' fer to see how they
 Trusted Fessler that away—
 Him a-lazin' round, and smokin'
 To hisself to see 'em workin'!"

"But old 'Bee,'" says Ike, says he,—
 "Now where is he? Where's he gone?—
 Where's the head he helt so free!—
 Where's his pride and vanity!—
 What's his hopes a restin' on?—

—Indianapolis Journal.

Every boy or girl, under 15 years of age, who writes a letter for this department, CONTAINING SOME VALUABLE FACT, NOT GENERALLY KNOWN, ON BEES OR OTHER MATTERS, will receive one of David Cook's excellent five-cent Sunday-school books. Many of these books contain the same matter that you find in Sunday-school books costing from \$1.00 to \$1.50. If you have had one or more books, give us the names that we may not send the same twice. We have now in stock six different books, as follows, viz. *Sheep, Off, The Giant-Killer, The Roby Family, Rescued from Egypt, and Ten Nights in a Bar-Room.* We have also *Our Homes, Part I, and Our Homes, Part II.* Besides the above books, you may have a photograph of our old house apary, taken a great many years ago. In it is a picture of myself, Blue-Eyes, and Caddy, and a glimpse of Ernest. We have also some pretty little-colored pictures of birds, fruits, flowers, etc., suitable for framing. You can have your choice of any one of the above pictures or books for every letter that gives us some valuable piece of information.

"A chief's amang ye takin' notes,
An' faith, he'll prent it."

MY little friends, we have not got quite so many juvenile letters this month as usual, but they are extra good, as you may notice. The reason is this: I have been obliged to let Ernest look them over, because of my multitude of cares, and he thinks a letter should not be published, even from the little ones, as a rule, unless it contains something of value. I presume he is right about it, but it seems a little hard to refuse to give place to any little letter, even though it may not be of much account, or a repetition of something that has been written a great many times before. You will all have to learn this lesson some time or other; and perhaps it may be as well to learn it now; that is, there is no excellence without great labor; and those who work industriously, and try hard, are the ones who will succeed. And to be consistent with my own teachings, I will stop right here and make *my* little letter (or letter to the little folks) a short one.

A HORSE STUNG TO DEATH BY BEES.

Two years ago this summer our bees stung my uncle's horse to death. My pa bought one of your Italian queens, and the ants killed it.

La Otto, Ind., Aug., 1885. ELLIS SIMON, age 10.

STUNG THIRTEEN TIMES.

Bees were first introduced into California in 1839, and into South America in 1810. The bee is the most useful insect there is. I was once stung thirteen times at once. I struck the hive once with a stick, and they swarmed upon me.

EUGENE HOLZER.

Allerton, Wayne Co., Ia., Feb. 13, 1885.

POKING THE ENTRANCE OF A HIVE.

Sometimes when I go past the hives to swing in the hammock, the bees sting me. I have been stung four or five times. Last summer I took a stick and poked it into the entrance of a hive, and the bees

came out and stung me in several places. I don't think I shall do it again. A few days ago one of my little kittens scratched me on the arm.

Acushnet, Mass. BERTIE BENNETT, age 3.

HONEY, BUT NONE TO EAT.

My pa took some honey out of the hive Saturday. The bees work very well. We have plenty of flowers around the grove for the bees to gather honey from. I like honey, but ma doesn't let me have much, for she wants to sell it. We have lots of applea and plums. We have lots of little pigs.

HULDAH WILLIAMS.

Banks, Minn., Aug. 23, 1885.

MARY'S NEW HOME.

My father and mother have just moved to our new home in the woods. My mother had to go to town the other day, and left me at home to keep house all alone. I looked out that no cattle came around to tip our bees over. We have six hives of bees, and want to get more. I like to read the children's letters. I never went to school, nor to Sunday-school, and I never had one of your books.

Campo Seco, Cal. MARY A. LUCK, age 8.

HONEY, FISH, AND CIDER.

We had 26 hives of bees when I wrote you the other letter. We got over 500 lbs. of comb honey. It hasn't a very good sale here. We get 15 to 17 cents per lb. We are making a fish-pond now, of 2 acres. There is a cider-mill going to start up pretty soon near our house. Do you think the cider will hurt the bees?

FRED W. ISRAEL.

Damascus, O., Aug. 7, 1885.

See A B C book in regard to cider-mills.

HOW MY PA CHANGED A BOX HIVE INTO A FRAME HIVE.

I must tell you how my pa fixed his box hives last spring. He took out the box above, and bored five rows of holes in a straight line, and he made frames to fit, and filled them with foundation; then put them in the space between the holes. We got plenty of honey. This way of getting honey from box hives is something new here, but it was a real success.

CHARLIE T. STEPHENSON, age 10.

Ripley, Ohio.

THE KITTEN, AND HER EXPERIENCE WITH BEES.

I have a little kitten named Moose. It was playing one warm day in front of one of pa's hives; and seeing the bees crawling out, it ran and put its paw on one bee, and then another. It thought it had found something funny to play with; but the bees got too hot for Moose; and I tell you, you would have laughed to see him run and tumble and mew. Poor fellow! He never went back there again.

Boothsville, W. Va. MAGGIE NUZUM.

BEES GOING AFTER WATER.

There is a meadow just below our house, which is rather swampy, and the day after a rain storm you may see a great number of bees going to and coming from this meadow before the water settles into the ground.

MILTON BENNETT, age 6.

Acushnet, Mass.

Friend Milton, the bees go down into the swampy ground for water. We have a fountain for ours, and we let on just water enough so that it drips over the edge slowly. The bees alight all around the edge, and seem to enjoy having a place where they can get water every day.

SELLING HONEY AT THE FAIR.

My grandpa has ten stands of bees. They are doing well. He and I went over to the fair to see if we could sell some honey.

Dexter, Maine.

BENNIE ELLIS.

A NOVEL WAY TO HAVE A SWARM.

Papa bought a hive of bees a year ago last December, at an auction, but they all died last March. The fore part of June, papa put the hive, full of empty comb, up in the top of the chimney. In a few days a swarm came and went into the hive. Papa took them down and put them on a stand, and they did very well. The fore part of August they swarmed. We now have two colonies of bees in box hives.

Lanesville, Conn.

FRED J. WANZER.

THROWING DIRT TO BRING DOWN A SWARM.

My father keeps bees, but I do not have much to do with them; but when they fly away, then I help to chase them. I helped stop a swarm this summer by throwing dirt at them. They are doing well. Father has kept bees a number of years. He can handle them without much trouble; he has them in the Simplicity hive, and has taken 96 lbs. of honey from 3 hives.

CHARLIE HUNT, age 11.

Amboy, Ill., Aug. 6, 1885.

WILLIE'S LETTER, AND HIS OPINION ABOUT SWEARING.

We had a swarm of bees come out three weeks ago last Sunday. Our bees nearly always swarm on Sunday. I am only a little boy, but I want to be as good as I can. On Sunday some of my neighbors' little boys swear, but I don't. I think it is awful wicked. Pa has an incubator. We have nice large Plymouth Rocks that were hatched in the incubator. The last time I wrote to you I had only one sheep; now I have two.

Memphis, Ind.

WILLIE COOMBS.

I agree with you, Willie, that it is "awful wicked" to take God's name in vain, and it makes me feel glad to know that there are little boys who can not be hired to do such wicked things for any consideration whatever.

MELONS INSTEAD OF BEES.

My father put 13 swarms in the cellar last winter. All came out alive in the spring. He had 10 hives transferred into the Simplicity; they are doing well. He has 27 swarms now. He has them in a plum orchard, and hardly ever loses a swarm; but he had one come to him. He thinks they are part Italians. My brother and I can make more raising melons. We have a large patch. We sold 12 dollars' worth last summer. There is something we can do, if we can not handle bees.

GEORGIE HUNT.

Amboy, Ill., Aug. 7, 1885.

By all means, raise melons, Georgie, if that kind of work suits you. The boy who *loves* the business, and sticks to it until he becomes an expert, will be almost sure to make money at it; and we might almost say the same of any other rural industry.

BEES STINGING CARP.

My father wintered, last winter, 140 stands of bees, losing one in March. We are feeding our bees now. The drought last fall killed the white clover here. Our bees have not made any honey this year to amount to any thing. We had 94 German carp, and our bees stung two in the mouth and killed them. Our carp are very tame. We can hold a

piece of bread in the water and they will come and eat out of our hand.

ANNA QUINBY, age 14.

Edenton, Clermont Co., O., Aug. 24, 1885.

BEES WORKING ON BUCKWHEAT.

My uncle has eighteen colonies. They are very busy nowadays. Uncle works among the bees, and they alight on his hands and on his back, but don't sting him, while if others go near the hives they get stung. If we go by the buckwheat and listen, we can hear the bees humming as they do around the hives.

ETTA B. PECK, age 13.

Banks, Faribault Co., Minn., Aug. 22, 1885.

AN OBSERVATORY HIVE; NOTES TAKEN BY A JUVENILE.

We have an observatory hive in our window, which has been there about three months. Pa uses it to raise queens. It had a queen fertilized last week; she was absent from the hive 38 minutes; she is now introduced to a fall colony, and the observatory is raising another one now. Pa has taken 457 lbs. of honey from six colonies, and increased to 14.

J. A. SHENEMAN, age 12.

Pharisburg, Union Co., O.

HOW TO GET A SWARM FROM THE TOP OF A YOUNG MAPLE-TREE.

My grandpa has 18 colonies of bees. He had a swarm in the top of a maple-tree. He tied the clothes-line to the top of the tree, then he bent the tree over and tied it to a plum-tree, then he swept the bees into the hive. My grandpa has two acres of buckwheat. Grandpa has two wild geese. They are so tame that they will eat right out of your hand. Their names are Punch and Judy.

CLIFFORD BUSS, age 9.

Banks, Faribault Co., Minn., Aug. 23, 1885.

BEES FOR MEDICINE, ETC.

I have been a reader of GLEANINGS ever since I was old enough to read. Pa started in last spring with 36 stands; increased to 46 by swarming. He does not let them swarm very much. He gives them plenty of work to do. Pa sold about \$100 worth of honey last summer, and every time he goes to town some want to know if he has got any more honey to sell, and he has to tell them no. He uses the Langstroth hives and the chaff hives. Did you ever hear of bees for medicine? Ma's baby was sick with the hives, and the woman doctor took one dozen bees and made tea of them, and the baby got well.

JESSE O. SWITZER, age 14.

Bucklin, Linn Co., Mo., Feb. 12, 1885.

Yes, Jesse, I have heard of bees for medicine. Your little story is almost a joke, but I presume you did not know it. You see, if the baby was sick with the "*hives*" it would be the most natural thing in the world to give it a tea made of *bees*. I suppose that by the term "*hives*" you mean a sort of breaking-out in large red blotches. Well, the poison from bee-stings is a remedy used very much by a certain school of medicine. That the remedy is a powerful one, there is no doubt. In some of our back volumes I have told you about selling poison-bags to the doctors for so much a thousand. Now, it would not be at all strange if this poison from the bee-sting were just the proper remedy, if administered in exactly the right quantity. A very little bee-poison will make one feel quite sick.

WARREN'S LETTER.

Thirteen years ago Eagle Lake was a forest, and now it has 300 inhabitants. My uncle is in the bee business. He makes his own fdn. My father is a soldier. I'd like to see Huber.

Eagle Lake, Minn. WARREN KEEBAUGH, age 12.

PROPOLIS MADE OF PAINT.

The bees do funny things sometimes. Pa made some paint, to be used hot. Some was left, and thrown out. When pa opened one of his hives ma said, "That is funny-looking propolis." Pa scraped some off, and smelled of it, and said it was some of that paint he threw out. There was nothing poisonous in it, except a little red lead.

ANNA BARSHAM RUSSELL, age 10.

Osteen, Fla., Aug. 5, 1885.

BROTHER FRED'S MISCHIEF: 25 STINGS ON HIS HEAD.

My papa has 50 stands of bees. He lost 16 swarms through the winter. We have taken off 800 lbs. of honey. I have one swarm of bees. My little brother Fred is two years old, and is very mischievous. He got stung 25 times on his head.

LANA LANGFON.

Windham, Portage Co., O., Aug. 9, 1885.

Whew! So your two-year-old brother got stung 25 times, did he? Why, some of the old veterans would make a howl if they got that many all at once. I should think your brother must be pretty good grit—is he not?

A "BIG GOOSE;" A SAD EXPERIENCE.

Grandma Koosa gave brother and me a pet goose. To-day it was going by the bee-hive, and the bees saw her, and oh how they did sting her! She ran and turned over and over, and jumped on the bee-hive, and rubbed her head, and you don't know how sorry we were. Our bees are good; they don't sting us at all. I think it is because none of us use tobacco. You know they don't like tobacco.

Border Plains, Ia., Aug. 8, 1885. FRANK KOOSA.

Why, Frank, that goose must have been a "big goose" for sure, to jump on the bee-hive after she had been "goose" enough to get so near the bees as to get stung. And so you think the reason why your folks don't get stung by the bees is because your folks do not use tobacco.

LETTER FROM A FLORIDA JUVENILE.

I have lived in Florida nine years, and have just started to make a flower-garden. Flowers do nicely, if anybody will take care of them. I have several kinds of flowers. I got a few geranium cuttings from Eva S. Glawson. She has quite a number of flowers. I think roses and magnolias are the prettiest kinds of flowers. I have got a nice madeira vine climbing up the window. It is about a foot long. They have a pretty flower.

I have four tame blue-jays. They will come and eat out of my hand. They are a pretty bird, and very tame. There are a great many kinds of birds here.

The bees have not done much this year. I like honey cappings better than extracted honey. Our oranges will soon be big enough to eat. The insects are not bad this summer. I guess they have all gone north to spend the summer. I got a letter from my aunt some time ago and she said that she saw a few flying about after dark, so I guess it is true about what I said.

MINNIE S. MENDEL.

Hawk's Park, Fla., July 29.

SEASON NOT FAVORABLE FOR BEES: STRAWBERRIES BY THE THOUSAND QUARTS.

Our bees are not doing very well; for in spring it was too wet and cold, and now it is too dry. They are working some on sand mint. This is the worst season for bees we ever had. We have 15 new swarms. We had lots of strawberries. Sometimes my brothers shipped as many as a thousand quarts a day. We did not have so many raspberries or blackberries, as it was too dry and hot here. I like to take care of bees better than I used too. I have them barefooted.

FRED WIRT, age 15.

Keithsburg, Mercer Co., Ill.

HOW JOHN'S FATHER MAKES A "POLLEN-SCRAPER."

The bees are getting lots of pollen from corn. Pa has made some pollen-scrappers. He takes a strip of tin as long as the entrance of the hive, and makes a row of holes in it, each a scant 3-16 of an inch in diameter, and nails the tin over the entrance; and when the bees go in it scrapes the pollen off their legs, and about noon I brush the pollen away, and take off the tins so the bees can take out the dead ones; and in the morning I put the tins on again.

JOHN RALSTON, age 14.

Vinton, Benton Co., Ia.

Very good, John; but what in the world does your papa or anybody else want a pollen-scraper for? I have heard of the friends having too much pollen in the hives, but I never saw a hive with too much pollen in it yet, especially if I were raising bees and queens for sale. And although I may be mistaken, it seems to me you will do your colonies damage by depriving them of the pollen they worked so hard to gather.

EDNA'S REPORT.

Our bees are working as fast as they ever have. They will be so thick in the air that I ask ma or pa if they are not swarming. They look just as if they were. I am watching the bees now. We had one swarm this forenoon. We have lots of new honey. Some is so white you can hold it up to the light and look right through it and see things. Our bees are not cross one bit. When the bees swarm and pa is not at home, and ma is doing something, and her sleeves are rolled up, and there is not a bonnet or bee-veil in reach, she will run out bareheaded to look for the queen, and the bees will not sting her. I have to laugh at her. Pa is not at home now. He is at the upper bee-yard, a mile from here. Novice watches the bees there; and when they swarm he runs down and tells pa, and then he rides up with pa. We have three large rabbits and seven young ones. We did have four. One was lemon color. We got them of Mr. Fradenburg. The lemon-colored one got away.

EDNA A. BOOMHOWER.

Gallupville, Schoharie Co., N. Y.

Thank you, Edna. It does us lots of good to hear from little girls whose papas we have known for many years, as we have your pa. You see, we shouldn't know that the papas had any little girls, if these same girls didn't write us nice little letters like yours.

HOW THE BEES ROARED ON BUCKWHEAT WHERE CORENA LIVES.

We have a big piece of buckwheat. The other day when I went to dig potatoes the buckwheat was covered with bees. I looked all over, and thought it was a thrashing-machine. I stick the foundation into the boxes for pa, and put them into the frames.

The queen that he bought of you a short time ago has done well. She filled the ten frames in Simplicity hives with brood over a week ago.

One day we had a swarm, and a king-bird caught the queen, and from one swarm the queen did not come out.

CORENA WILLIAMS.

Banks, Faribault Co., Minn., Aug. 23, 1885.

Well, Corena, that is pretty well expressed. The bees made such a roaring on your buckwheat that you thought it was a thrashing-machine. I should think likely your buckwheat is doing nicely. We have a field of about one acre that begins to look very handsome; in fact, it pleases me the best of any piece of buckwheat I ever had. It was sown with a grain-drill, and we put in 300 lbs. of phosphate to the acre with the seed. The next time I hear bees humming on it in the morning, I will stop and listen, to see whether it sounds like a thrashing-machine or not.

TOBACCO COLUMN.

A NEIGHBOR'S INFLUENCE.

I SOLD a neighbor a few colonies of bees last spring; and as they were blacks I told him he would need a smoker. He thought he couldn't afford to get one, so I told him about your offer in GLEANINGS. Well, he came over to-day and asked me to send for a smoker for him. He said he had used no tobacco for six weeks, and thought he could "stick to it" (he has used tobacco for twenty years). He says, "Tell Mr. Root if I ever use it again I will pay for the smoker." If he doesn't, I will.

S. L. ESLER.

Duplain, Mich., August, 1885.

I saw in your journal that you would give a smoker to any one who would give up smoking. I gave it up the 4th of July, and intend never to smoke again, whether you send the smoker or not. I have three hives of bees.

HOMER CHARLTON.

Gorham, N. Y., July 21, 1885.

I have read GLEANINGS some, and saw your offer to give a smoker to those who quit using tobacco. I have, with the help of God, quit chewing and smoking. Will you please send me a smoker? If I use tobacco in any form again I will pay for the smoker in full.

C. W. TRACY.

Plymouth, N. Y., May 26, 1885.

I have received the queen and frame of brood. The bees you sent me are all right, and I am well pleased with them. I introduced the queen to a hive that was queenless, and it works well. One of my neighbors has quit using tobacco. Will you please send him a smoker? If he ever commences using tobacco again I will make him pay for that smoker, if you send him one.

W. HIETAND.

Palm, Pa., July 17, 1885.

I have quit the use of tobacco. After using it and cigars for ten years, I came to the conclusion I would try to quit chewing and smoking. I have done so; and now if I am entitled to one of your smokers, please send me one. If I begin using it again I will pay you for it. We have four stands of bees, and they are doing extra well for this season. Basswood has been booming.

ELMER OWENS.

Woodstock, Ohio.

You have persuaded me to quit the use of tobacco. Thanks. You may send me a smoker; and if I am not faithful I will pay for it.

B. H. MOBLAY.

Girard, Ga., May 23, 1885.

QUITTING THE USE OF TOBACCO WITH GOD'S HELP.

I have not used tobacco for about four weeks, and I intend, with God's help, never to use it again; so, please send a smoker, and help a brother in need.

S. H. WETMORE.

Wellsboro, Tioga Co., Pa., May 22, 1885.

HOW FRIEND C. QUIT THE USE OF TOBACCO.

In the year 1858 I quit the use of tobacco, having chewed and smoked the filthy weed for ten or twelve years. I found it was injuring my nervous system. It was a three months' fight; but, the victory was gained, the battle does not have to be fought over again; why? Because I gave my testimony against it — "This is the victory that overcomes the world, even our faith." Faith in whom? In God our Father, and Jesus Christ our Savior.

J. C.

INFLUENCE OF A FRIEND.

I was at the store to-day and met one of my neighbors who is a bee-keeper on a small scale. He purchased 5 lbs. of tobacco, and I told him of your offer to give any one a smoker, who would quit the use of tobacco in every form. He said that if I would write to you for a smoker he would quit. I told him I would do so. He gave back the tobacco and took coffee instead. He promises to pay for the smoker if he ever breaks over. I have induced another one of my neighbors to quit, and he makes the same promise. I think they will hold out. They are both members of the Christian Church.

Quinnimont, W. Va.

S. L. CARPER.

QUITTING THE USE OF TOBACCO "FOR CHRIST'S SAKE."

I have procured you a new subscriber to GLEANINGS. He is trying to quit the use of tobacco for Christ's sake. He has not used it now for several months. He was an inveterate smoker and chewer, but is determined, by God's help, never to use it again. Can you not give him a smoker to encourage him? He is a poor man, with a small mortgaged farm; enlisted in the army when he was fifteen, and served through the war; and through my influence he is becoming quite interested in bee culture. I think you will receive an order from him this fall.

J. F. TEMPLE.

Packerville, Ct., June 5, 1885.

ONE WHO HAS USED TOBACCO FOR THIRTY YEARS.

I can not do without GLEANINGS, even if it is a little mixed with bees, fish, potatoes, strawberries, and tobacco. I am glad to see some one keeps trying to break the chains of that miserable slavery of tobacco. I was a slave to it for over thirty years, both chewing and smoking to such a degree that I knew nothing but smoke, first in the morning before I could dress; at night I lay down with my pipe in my mouth. It often cost me 30 cents per week, besides ruining my health, dulling my nature to any thing but tobacco. I made up my mind to quit on the first day of Jan., 1881, and have never touched, tasted, or handled since; but I tell you it was a struggle. I do not write this to get a smoker. I have one of your make. I am well paid in health, as well as a dozen other ways. I think if a man gives his hearing in one month, he is well paid.

Marlette, Mich.

J. H. KIRK.

OUR HOMES.

I, even I only, am left, and they seek my life, to take it away.—1. KINGS 19:10.

I SUPPOSE most of the friends are familiar with the circumstances under which Elijah spoke these words. Elijah was a great prophet. God honored him in life, and God honored him by translating him that he should not see death. He commissioned him to perform miracles such as no human being had been permitted to perform before. Elijah was a great reformer. He surely hungered and thirsted after righteousness. But with all his bravery, and with all his devotion to the cause of righteousness, he seems to have been human, like ourselves, and was given to complaining and fault-finding at times, it would seem. James mentions this where he says:—

Elijah was a man subject to like passions as we are, and he prayed earnestly that it might not rain; and it rained not on the earth by the space of three years and six months.—JAMES 5:17.

He was just the man for the place and the times; and when God commissioned him to meet Ahab, to tell him of the famine that was to come on the nation, he took up fearlessly the task that perhaps no other man in the kingdom would have dared to perform.

We know nothing of the early history of Elijah. We only know that the general impression seemed to prevail that God was accustomed to deal with him in a miraculous manner. Even as good a man as Obadiah, was afraid that God might take the prophet away by some sort of "sleight of hand," and leave himself the victim of Ahab's fierce passions.

Elijah had a simple, childlike faith in God that fitted him for the work he was called upon to do. There was nothing in his composition to indicate the least particle of pride or love of display. The historic mantle, which has been a synonym for ages, was probably a simple garment made of sheepskin or leather; and whether he was alone in the wilderness, or standing before the king, his attire was probably just the same. He was one of the great minds of the age, and eminently fitted for calling down fire from heaven, or invoking the storms from across the sea; and through it all we may readily believe there was not a spark of pride or self-glory. It was God's honor he was defending, and God's righteousness that he wished to see prevail; and because instant reform among the children of men was not a prompt result of his great miracles, he became dissatisfied and impatient, and complained even to the angel of the Lord himself.

How often we see the same spirit manifested nowadays, even by some of God's greatest servants! and most of us, too, perhaps, who have been hungering and thirsting after righteousness have felt some of Elijah's impatience and want of faith, because God's work seems in our eyes to move with unreasonable slowness. Every little while somebody says the cause of temperance is not moving on a bit—we are just where we were years and years ago. All

the energy and zeal which has been put forth amounts to just nothing, or, at least, the effect is so soon swallowed up in this gulf of iniquity that we might as well give up and let the thing go on.

A friend of mine once said to me, "The men *all* drink—at least, there is hardly an exception." I think of it sometimes when it transpires that one whom we supposed was almost the soul of honor and temperance, has been taking stimulants for his health because "the doctor advised it," or something of that sort; and when after a little time he turns out to be openly intemperate, I begin to wonder if there is really *anybody* to be relied on. I feel ashamed of myself, however, soon afterward; for if I don't remember the words of reproof that God used in replying to Elijah, I at least recover my own good common sense. In the 18th verse of the same chapter our text comes from, God tells Elijah that there is not only *one* more like himself who is hungering and thirsting after righteousness and godliness, but that there are in Israel *seven thousand* whose knees have never been bent for one moment to Baal, and whose lips have not touched the disgusting idol. And now, then, the point of my talk to-day, dear friends, is going to be a good deal in the same place where it has been so many times before—more faith in God, and more faith in our fellow-men.

A few weeks ago I wonderfully enjoyed paying a visit to our friend Terry, of potato notoriety. After I got home I wanted to tell all about this visit, on about four pages of GLEANINGS; and as some would say it was not bee culture, I concluded I would put in two extra leaves, making it gratuitous. It seemed to me that the amount of good done by a minute account of friend Terry's farm and farming operations would warrant the outlay. Perhaps I shall do it yet; but I think I could have done it better while the incidents of the visit were fresh in my mind, and when I was full of enthusiasm on the subject. Why didn't I do it? Well, because I began to be afraid it was not best.

A year or two ago, while our daughter was in school, she felt greatly hurt because the lady who had charge of her department objected to her making occasional visits home, even when she was terribly homesick. I wrote to the lady principal in regard to the matter, and she replied that she knew it seemed hard, but that she could speak positively from years of experience, that, when pupils went home, their mind was for the time taken from their studies, their interests were divided, and it was very undesirable. Where you wish to have a pupil make steady and healthful progress in her studies, her interest must center all about these studies, and we should aim to avoid any sort of diversion or a dividing of these interests. Well, I was led to think that even these two leaves, given gratuitously, might divide the interest of the readers, and that perhaps a little book about the size of the potato-book, with proper illustrations, would be the better way, then those who don't care about Terry and his success in agriculture need

not even have the matter brought before their eyes unless they care enough about it to send for the book. Now to get back to our subject.

At the same time I visited friend Terry I called on and took along with me Mr. D. E. Fenn, of Tallmadge, O., a relative, and a very successful farmer, fully up to the times. It was a rare treat to me to hear these two great enthusiasts talk as we walked over the fields and went through the barns. Both Mr. Terry and Mr. Fenn have nice tools and farming machinery, clear up to the times, and Mr. Terry has just built the most beautiful tool-house I ever looked at or thought of. It is just "a thing of beauty," and, I dare say, to him "a joy for ever." I am going to give you a picture of it some time, any way. I want to mention right here that Mr. Fenn has a German in his employ who is so careful of his hoes and spades that he keeps a cloth in the proper place, with which to wipe off all the dampness and soil before they are put away for the night. After they are wiped so the bright polished steel is handsome to look at, he takes another cloth, saturated with oil, and oils all the bright parts. This absolutely prevents any rust on their bright surface; and if you do not know the difference between a bright shining hoe and one covered with heavy rust, when you start out to work just try two hoes—one rusty, the other bright. A man would accomplish a fourth more with the clean bright tool, and save his strength besides, because the bright hoe slides into the soil so easily, and the same soil slides off so that the tool will keep itself clean. Mr. Terry keeps the tools in his tool-house a good deal in the same way. They are nicely put away, and very handy and convenient doors right in front of each tool permit it to be reached at once without clambering over other tools. The same with his plows and harrows.

We are getting further and further from the subject of Elijah and his complaint, are we not? Well, let us see. I asked Mr. Terry if he was in the habit of lending these nice tools to his neighbors. He replied, that it was generally understood that he did not lend any thing; it was impossible for him to do so. The importance of succeeding with his work as he does succeed, depends greatly on having the right tool ready to be used the very hour it is wanted, and sometimes without the delay of even five minutes, when the weather is treacherous, as it has been this season. Mr. Fenn remarked, that one of the greatest troubles in his life was the trouble in regard to borrowing tools. As the conversation was started in this direction, one told a story about the annoyances he had suffered, and another told a story, and these stories reflected so sadly on my fellow-men that I felt badly about it, and have been feeling badly about it ever since. May be I told some of the stories too. When my conscience began to trouble me I remarked, "But, Mr. Terry, you surely have some neighbors who would take as good care, or better care, of borrowed tools than they would of their own, — who will always return a tool exactly as they promise to do, or sooner, who also recognize what it costs you

to keep such a stock of tools carefully housed, and will insist on paying you handsomely for the use of these tools?"

Now, I do not know that the above are exactly the words I used, but it is what I had in mind. Mr. Terry is a Christian man, and, as a rule, is not uncharitable. He sees the faults and failures of his brother-farmers; but I do not believe he exaggerates — at least, as a general thing. I wanted to hear him say that there were at least a few around him who were exceptions to the general run of people who borrow, and I also wanted to hear Mr. Fenn give a good report of at least a few of his neighbors of the township of Tallmadge, where every farmer seems to be thriving and prosperous, but I was disappointed. Mr. Terry said he did not know of any such. Mr. Fenn said the same thing substantially. Now, then, my friends, you and I are the folks who borrow tools. Do we average better than Mr. Terry's and Mr. Fenn's neighbors? I don't think we do, unless it is because we read bee-journals and agricultural papers, and their neighbors don't, but I can't believe that is so.

Elijah kept saying over and over, "And I, even I only, am left." Had he reflected a minute he would have recollected the fifty prophets that Obadiah mentioned; but he had in mind at the time only Ahab and Jezebel — those hateful persons and their worshipers, and he "sort o' forgot" about the rest who did not force themselves upon his notice. Now, I am inclined to think that it was the same with our good friends Terry and Fenn. When I asked them to recall to mind, they did not think of certainly a dozen good honest unselfish men — men who are never known to put anybody out of the way without making restitution so far as they could. Yet I think there must be at least a dozen in their own vicinity who have never troubled them by borrowing tools; or if they did, who gave value received, or more, in other ways. We remember things and people that vex us, but we don't remember things and people that don't vex us; that is, we forget favors, but we don't forget perplexities so easily.

Now, then, what is the result of settling down to the decision that mankind are so depraved we might as well give up? Elijah went away into the woods and sat down under a tree, and asked God to take him out of the world. He gave as a reason for his request, that he was not better than his fathers. He was discouraged and disappointed. He was displeased with God just as we are displeased with him when we complain in that wholesale manner of our fellow-men. Is it a good frame of mind to be in? Are we standing just where a Christian man ought to stand, when we decide that the bulk of mankind are so slipshod, lazy, indolent, selfish, that there is no use in trying to be neighborly? I hope friend Terry will excuse me if I seem to be personal. I do not mean to be; or, at least, I mean to put myself in the same boat when I criticize. In the potato-book, friend Terry tells us about what it usually cost one of his neighbors to get his potatoes dug. The neighbor

remarked that it generally cost him so much a bushel, including mowing down the weeds to get at the potatoes. Some of friend Terry's neighbors will have to mow down the weeds this fall before they can dig their potatoes, I fear; and the general appearance in his vicinity indicated that his neighbors—at least some of them—were not more go-ahead than he had given them credit for being; that is, in his writing on agriculture. And the need of reform is not confined to his own locality—it is widespread. But, dear friends, we make a sad, sad mistake when, in looking at these evils to be encountered right and left, we forget or omit to take into consideration the good traits as well. I shall have to confess right here that it comes so extremely natural for me to find fault, and to criticise, that I find it hard to get over my besetting sin in my *illustrations* even. Let me try here.

My cousin, Mr. Fenn, told a story something like this: He had a nice new harrow, with the teeth all bright, and the woodwork nicely painted, and he was so choice of it that he would not even let it be out one minute in the rain. A neighbor wanted it. He hated to say no, just as you and I do; and after a fair and square promise that it should come right straight back because he was going to need it, it went out of the barnyard. The time came when he wanted to use it, and business was hurrying, and there was no time to go after it, so he got along with a rickety old one. Finally he met the neighbor who borrowed it, and asked him about it.

"Why, I lent it to Dr. W., and he said he would fetch it right home, just the minute he got his ground fixed."

It did not come, and after a few days they got over needing any harrows. Some time in the middle of our last long cold winter, Mr. F. was passing the doctor's residence, and down in a sluice-way by the side of the road he saw some sharp points sticking up out of a huge block of ice. These points looked like the teeth to that nice new harrow. He is quite a man for dry jokes, so he stopped at the doctor's residence and called attention to the matter something in this way:

"Look here, doctor, there are some sharp-pointed instruments sticking out of that block of ice down there that seem to me a little dangerous. If somebody should get thrown out of a vehicle, and alight on them, it would be a terrible place to fall."

Having delivered his message, he turned around to go; but the doctor exclaimed, "Why, I declare, neighbor F., I do believe that those points are the teeth to your harrow, which I very carelessly neglected to return as I promised to do. I am very sorry—" etc. I do not know when the harrow got home—probably some time in the spring, when it got thawed out of the ice. Do you ask why I tell such a story as this when I am trying to make a plea for poor humanity? Well, I have told it because I want to say that, in all probability, Dr. W. is a good man in spite of this bad habit of his. As his profession implies, he is a public servant, and, I dare say, a whole-souled, and, generally

speaking, faithful servant. Borrowing tools, and leaving them to be frozen in blocks of ice, is a grievous fault, I admit; but it is by no means the worst fault a man can be guilty of. Perhaps it does not compare with things that you and I are guilty of at this very moment. Men who are guilty of these faults are, as a rule, those who are large-hearted, liberal, and accommodating. I do not recommend this kind of "large-heartedness," mind you, but I do recommend that we take hold of such obstacles fairly and squarely and cheerfully. What I mean by obstacles is sins like those I have mentioned. Don't get into a way of saying, "'And I, even I only,' am the only good man in the neighborhood." Why, what an awful thing it is for you to get the idea into your head that your neighbors are all full of faults, and that you alone are perfect! May be you are ahead of them in some thing—you ought to be—but very likely they are ahead of you in ever so many other things. "We be brethren" is a thousand times better to think, than to get up on our high-heeled shoes and keep saying over and over to ourselves, "I, even I only."

We have trouble with the railroad and express companies. We say they have no souls. Words and phrases have been coined, especially by the farming community, to express how these large corporations will cheat and swindle people. I am guilty too, dear friends, and I pray that God may forgive me, and help me to do better. I know I have taken the part of the railroad and express companies several times; and after having done so there is a kind of feeling in my heart that I have done right. I feel a great deal happier for having tried to think of their good qualities, than to settle down into such wholesale denunciations as we often do. Almost while I am writing, some money has been handed in from the railroad company for wax they lost out of a barrel last February. It took a long while, it is true; and I think I have been in the habit of saying, in an ironical sort of way, "It takes them for everlasting to right a wrong, if they ever *do* get to it at all." Such an expression is not right. Our shipments go over a great many different railroad lines, frequently. It is a complicated matter to trace it back and decide where the fault lies, even if it is possible to decide at all. Our short line of road, to whom the complaint is first made, receives only a few cents for handling a barrel of wax. In running over the papers for tracing up overcharges, shortage, etc., I have sometimes noticed that one company would receive an amount as small as nine cents, seventeen cents, or some odd amount of change, showing how carefully and minutely the profits were divided up. Now, with even this small pay they frequently have to go through a whole string of papers to get a little wrong righted. Is it any wonder that it takes them a considerable amount of time? Are we not, dear friends, a good way off from where a Christian ought to stand, when we speak as we do about their delinquencies? "We farmers are honest; but the railroad companies steal and lie and cheat, and won't make any thing right, even

where we place it plainly before their eyes." Does it help one along in life to get into this frame of mind? and does it help him on in the pathway to eternal life?

Such a spirit of complaining, and rushing to the conclusion that somebody is false while we alone are true, grows on one. It is like intemperance and other terrible sins. If you rush to the conclusion that one of your neighbors is dishonest, in a few days you will discover that another one is more dishonest, and so on. Pretty soon you become a misanthrope, hating your fellow-men; then you hate God, then creeps in the hideous demon of suicide, and the end is—where? The direct opposite of this is a bright faith in God and in man. A few days ago a difficulty was laid before me, between a purchaser and a shipper of queens. Because of some trifling misunderstanding, one called the other a liar. Why, my friends, such words are awful. No doubt the man who sent out the queens was in the wrong; but what he said was nothing near what might be called a deliberate lie. It is a fearful thing to get into such a state of mind over business matters that you feel like calling one of your fellow-men a liar, and still worse when you do so far forget yourself as to put it in words. When you get into such an attitude of mind that you feel like being cross at every thing and everybody, please remember the words of the angel of the Lord to Elijah—"Yet I have left me seven thousand." Since that history was written, the world has improved in godliness and righteousness. I think there is no question of that. There is iniquity abroad in our land, it is true; but we can always rest assured of this, when we feel tempted to give way to uncharitable thoughts and feelings: As we are, so is the world. The generality of your fellow-men average, in God's sight, about as you do. You have no right for a moment to insist, or to allow yourself to get into a way of thinking, that the rest are corrupt, and that you alone are pure. In fact, the truest indication that a man is getting to be low down in the scale of godliness is his inclination to exalt himself and to decry others. Find a really godly man—one whom the world unites in reverencing and respecting, and watch his conversation, and see if you can get him to denouncing people as a class, corporations as a class, or even political bodies. I tried the experiment only yesterday. An old friend who is known because of his Christian spirit and faultless life, took supper with us. I hope he will forgive me when I say that I purposely started him on politics, and led the way a little, to see if I could get him to speak ill of any of our political parties, or even of politicians as a body. His childlike simplicity, and faith in his fellow-men, as he plead for them all, one after another, was a lesson and a rebuke to me. May God help me to carry such a faith and charity and loving kindness toward all my fellow-men! to be ready to defend them, and to speak of their good qualities whenever they are assailed by this sort of unkind wholesale criticism that I have been trying to speak against in my talk to-day. How very, very closely does love to our fellow-

men come in with love to God! and this brings us back again to the words of Jesus to the wise lawyer:

Then one of them, which was a lawyer, asked him a question, tempting him, and saying, Master, which is the great commandment in the law? Jesus said unto him, Thou shalt love the Lord thy God with all thy heart, and with all thy soul, and with all thy mind. This is the first and great commandment. And the second is like unto it, Thou shalt love thy neighbor as thyself.—MATTHEW 22:35-39.

For a month or two back I have been very happy, and I think the happiness has, a great deal of it, come along in the line I have just been talking about to-day. When somebody or some class of people have been censured severely, I have tried what the effect would be to take their part, and remonstrate against unjust and uncharitable criticism. I have tried to think of the better phases of humanity; and doing so I have become happier, and, I trust, better myself. It needs only a very little remonstrance, or a very little suggestion, kindly put, to stop conversation when it starts in this line. People are usually inclined to assent when we put in a plea for an absent one, and I have generally found them quite ready to take up with the better side of almost anybody, when it is suggested to them in a Christianlike spirit. Such an attitude is a hopeful one. One who loves God and his fellow-man is always hopeful. He is always glad that he is alive, and, no matter what trials or obstacles beset him, he has something to rejoice over.

Years ago, during my first Christian experience, I mentioned that there were times when God's love seemed very precious to me—that I could feel, as it were, a sort of companionship—that I was not alone. Well, I have felt this a good deal lately. Sometimes bitter denunciations have been uttered in regard to certain political parties, or certain religious sects, it may be. When I have taken the part of these people or classes, a feeling has come over me as though some presence were near; and this presence seemed to say, "Dear friend, you are getting on the right track; go on, and fear not." And when I have put in a plea in the way I have told you, I have thought of this text I have quoted: "I have left me seven thousand in Israel, all the knees of which have not bowed to Baal." There is something wonderfully comforting in this thought: That God's own image is still to be found in humanity, with all its sins and weaknesses, and that often only a little encouragement is needed to bring out this image of God, and let it shine forth. Who could for a moment think of considering life a burden, or mankind as enemies, or the pleasures and pursuits of the world as unsatisfying, while his heart is filled with these bright hopes that only a faith in God can inspire? There is a little verse in the last chapter of Zephaniah that I sometimes think of at such times. It is a little odd and singular; but yet after such experiences as I have told you of, there is wonderful beauty in it.

The Lord thy God in the midst of thee is mighty; he will save, he will rejoice over thee with joy; he will rest in his love, he will joy over thee with singing.—ZEPHANIAH 3:17.

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

A. I. ROOT,
EDITOR AND PUBLISHER.
MEDINA, O.

TERMS: \$1.00 PER YEAR, POSTPAID.

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, SEPT. 15, 1885.

Thinketh no evil.—Cor. 13. 5.

OUR SILVERHULL BUCKWHEAT AT THIS DATE.

TO-DAY, Sept. 14, the bees are just roaring on our Silverhull buckwheat. If it is not beaten down by the storms, nor killed by premature frost, we have the promise of an abundant crop.

MORE SLANDERS ON THE BEE-MEN.

AND this time it is the N. Y. *Witness* that goes on fearfully about the way that honey is adulterated, comb honey at that, and ends up by saying, "Let us have pure honey, Mr. Bee-man." And now we say, Mr. *Weekly Witness*, be sure you are right, before you accuse your neighbors of fraud.

EXHIBITS OF HONEY ON THE FAIR-GROUND.

AS we go to press we are busy filling the little building, 12 x 16, which has been put up at our own expense on our county fair-ground. The building cost about \$103, and is to be permanently our property. It covers a pyramid of packages of honey, both comb and extracted. The latter embraces everything from an iron-jacket can down to a paper pail of honey small enough to be retailed at a nickel. The managers of our fair give us the ground for the building and permit us to retail honey during the three days of the fair, in consideration of the display we make, and that we keep a man present to talk with bee-men, and explain all about a hive of bees kept near by, and the various implements for bee culture kept on exhibition.

GOODS FOR NEXT SEASON'S USE.

ON hives and other fixtures that are purchased now, to be used during the season of 1886, we will allow a discount of 5 per cent; and this offer will be good until Nov. 1. We mention it thus early, that the friends who have small orders to make this fall may be induced, by the discount, to have heavier articles for next season go with them, thus in effect saving freight. Simplicity hives, honey-extractors, section boxes, brood-frames, etc., would come under the discount given. Chaff hives would not, as they are mainly intended for winter use. This discount comes in addition to all other discounts given for other reasons. Comb fdn. ordered now, to be used next season, will be subject to a discount of 10 per cent, and the above-mentioned 5 per cent, from our list price. We do not change our prices on comb fdn., because we are unable to say how the wax market will stand next spring.

THE STATE FAIR AT COLUMBUS: THE HONEY YIELD FOR OHIO, ETC.

PERHAPS I owe an apology to the bee-friends in Columbus for not being present the last day of the convention held during the fair. I visited the Agricultural College and Experimental Farm early Fri-

day morning, and was prevented by a rain from getting around as I had intended. The show of comb honey at the State Fair was not extra this year, owing to the fact, probably, that the yield of honey round about Columbus has been rather poor. The northern part of the State of Ohio, and also in Michigan and other northern States, the yield seems to have been excellent on the whole. The honey on exhibition was mostly built without separators. This of itself, however, need not necessarily have made it not first class in appearance; but coupled with the poor season it would probably have that effect. The nicest honey we have ever handled we are selling now, and it was all secured without the use of separators; but the sections are the narrow ones, only seven to the foot.

MATTER THAT WE CAN NOT FIND ROOM FOR.

IT pains me almost every day to be obliged to forego the pleasure of publishing good letters on many subjects. For instance, some very kind words, and some very able papers, have been written in regard to the "mix" in GLEANINGS; but as the matter has been sufficiently discussed already, it does not seem to me that we can afford to take space for it any further; the same in regard to "dry fires." It seems to me that this question, like a host of others, can not be settled definitely. Both parties are right in one sense, and both parties are wrong in one sense. It seems to be more a matter of opinion in regard to terms, than because there is any thing further to be brought to light; and, like many other questions that are hotly discussed at great length, I can not discover that there is any important point involved in the matter. May be I am not posted. If so, it is my misfortune, and I shall be glad to hear what the friends may have to say, that I may become better posted. But I hope you will excuse me for declining to put them in print, unless something very much more important is submitted than has been brought forward.

REDUCTION IN PRICES OF THE PASTEBOARD BOXES, OR "CARTONS," FOR HOLDING THE ONE-POUND 4 x 4 1/2 SECTIONS.

AN immense trade has sprung up in these boxes; and as a consequence of being able to give the manufacturer larger orders, we are able to put the prices as follows: Single boxes, 2 cts.; in lots of 25, 10 the flat, 30 cts.; 100, \$1.00; 1000, \$9.00; 10,000, \$80.00. If wanted by mail, add \$1.00 per hundred for postage. Colored lithograph labels, \$3.00 per 1000. There are two different kinds of these labels, so you can have the two sides of the carton show a different picture. Where you wish the labels pasted on before shipment, add 10 cts. per hundred for putting them on. Sample box by mail, with a label on each side, 5 cts.

Your name and address, and the kind of honey, may be printed on these labels, the same as other labels. The charge for so doing will be 30 cts. per 100; 250, 50 cts.; 500, 75 cts.; 1000, \$1.00.

There has been quite a little call for a similar box to hold a 2-lb. section. The trouble of getting this up is, that there is no regular size for a 2-lb. section, as there is for a 1-lb. section. We can have them made, however, to order, for just about double the above prices, and the manufacturers could not very well make less than a thousand of any particular size. If the friends will agree on the dimensions of a 2-lb. section, we can have a box made for about a half more than the one-pound.

KIND WORDS FROM OUR CUSTOMERS.

Please forward, as soon as possible, goods named in order. I sold the other crate of smokers all in a day, and they went like "hot cakes." S. FORT.
State Center, Ia., July 23, 1885.

The goods ordered of you July 2d arrived on the 18th inst. Every thing was entirely satisfactory in time of transit and quality of goods. G. W. MORE.
Puyallup, Wash. Ter., July 20, 1885.

The queen you sent me came all safe, and is now doing her duty. She was the best-looking one I ever received. Many thanks. L. H. LANGWORTHY.
Riceville, Pa., August 10, 1885.

I thought that I would write you that I have received the honey-labels all right. They are very much nicer than the one in the sample-book, and are the neatest and prettiest honey-labels I ever saw. Bees are doing pretty well now. Slaght's, Colo., July 12, 1885. W. H. PRICE.

A notice of the ABC of Carp Culture appeared in the last issue of the *Egis*, a copy of which I send. I have carefully read the work, and think it and the ABC of Potato Culture should be in the hands of all intelligent agriculturists. WM. H. CATHER.
Ashville, Clay Co., Ala., July 3, 1885.

I sold out my bee business last fall, but I like your journal well enough to continue taking it, whether I invest in bees again or not. Continue your footnotes and Home Papers, by all means. I should be glad to hear more of Florida, Cuba, and Apis dorsata. E. LOOMIS.
Anamosa, Ia., June 21, 1885.

I received the ABC book, together with GLEANINGS and your price list, last Saturday. I have run my eye over the book, and I see a great improvement on the copy I had lent me. I am pleased and delighted with the book, and I consider it well worth the price. ALFRED DONBAYAND.
New York, Feb. 9, 1885.

The select imported queen was received all right; some of her queens are out, and are perfect beauties. Thanks for promptness. I know what it is to receive queens by return mail, and shall try to fill my orders hereafter in like manner, as nearly as possible. I like to treat customers just as I like to be treated myself. C. WECKESSER.
Marshallville, O., July 20, 1885.

SENDING NUCLEI TO THE ROCKY MOUNTAINS.

The two-frame nucleus ordered of you came through in splendid condition. I don't know what the little fellows thought when I turned them loose up here in the Rocky Mountains, 10,000 feet above sea-level; but I do know that they went to work like "Trojans," and I never saw bees do better in my life. J. C. PADDOCK.
Brookside Ranch, Leadville, Colo., Aug. 10, 1885.

The select tested queen to replace you sent Monday, the 24th inst., arrived in good shape on the evening of the 25th. On the morning of the 26th I killed the drone-laying queen, got this queen from the postoffice, and introduced her in the afternoon. She was accepted by the bees the next day, and laying eggs. She is a fine queen and a good layer, for she has now laid about half as many eggs as the other did during the whole time I had her. Please accept thanks. A. VANDEREIKE.
Lake Mills, Wis., Aug. 29, 1885.

OUR 24-LB. SCALE.

I received the double-beam scale and other goods, in first-class shape. A neighbor said the other day, "It's queer you have to send to Root for every thing." He then hunted up his price list of scales, and could find nothing that would suit us for less than double the price of your scales. It's worth something to know that you will get honest goods for your money, and that they are safely packed to ship. T. YOUNG, JR.
Lasalle, Ill., Aug. 8, 1885.

[Many thanks for your kind words, friend Y., and I will try to deserve them.]

I received the bill of goods you sent, long ago, and it seems that I might have reached the limit of your patience in waiting for me to remit the balance. But your patience and kindness are only exceeded by your promptness and care in sending the goods. This is a good bee country. The season has been almost a failure so far. The main honey harvest is from sourwood, which opens in July.

W. J. TIDBALL.
Kilby, Alexander Co., N. C., June 22, 1885.

This is to thank you for the timely and excellent Home Paper in your issue for Jan. 15. It is an excellent lay sermon, and came from the heart, and will strike many, and I hope, call a halt. Could it be preached from all the pulpits in the land—that is, the text as appropriately handled, it would do great good, and check a little the struggles which make so many Americans unhappy, and so many homes miserable. There is not, and never has been, such a tendency in the old "slave States" to "drive for wealth." There is more ease and leisure, if less of luxury, and I regard it as well that it is so. I have had to struggle against the very tendency to overdo, and yet I often find myself wishing that I had a less exacting business and more freedom. It is not all caused by a desire to display, but more to surround the house of the dear ones at home with comfort, which prompts so many Americans to strive as they do. J. W. PORTER.
Charlottesville, Va., Jan. 27, 1885.

Allow me to express my sincere thanks for the promptness and care with which you filled my order, together with the good judgment displayed in sending just what I wished for, as I could not have been better suited had I selected the articles myself.

The ABC book pleases me very much; it is really an excellent work on the subject, and should be found in every library, also in possession of every one who intends embarking into this most interesting and instructing subject. The further I read, the more I like it; for its arrangement is so perfect that, should the bee-keeper find himself in any predicament, or want of information, it may be found and read in this valuable book in a moment, leaving the apiarian to proceed knowingly, and without further trouble.

GLEANINGS is a very good paper on the subject, and should be in the hands of every progressive bee-keeper, that he may read and be benefited by the experience of all the noted apiarians, as well as to give his own, or ask for information in regard to difficulties which may arise. Taken in all, I would not part with either, for any consideration, were it impossible to procure another. C. H. THEBERATH.
Newark, N. J., Aug. 21, 1885.

I have inclosed a dollar bill in this to renew my subscription to GLEANINGS. I am sorry I have neglected it so long past the time it ought to have been paid, for I don't want to miss one number, for myself and family are greatly pleased with it, especially its Home Papers and children's columns, and all of us only wish we could be more personally acquainted with the man who can write such nice papers. I see some readers are wishing you to leave out Home Papers, articles on fish, potatoes, etc. For my part I should be very sorry to see it done, for those Home Papers are doing a work that can not be done in any other way, for hundreds see them who would not take a religious paper at all. I see a number of papers myself on various subjects, but I should like to see GLEANINGS continue as it is. Go on, Bro. Root, and may God bless you in your work.

As to bees, I am not a very large bee-man. I bought three swarms two years ago this spring; increased to four the same summer; went into winter quarters last fall with the same number (having no increase at all last summer); lost one in wintering and had three this spring—two weak and one moderately strong. I have had but one swarm this summer, and that went off to the woods after hiving it two or three times, so that I am just where I started, as regards number, though I can not say that I am any money out of pocket by bees, for I think the honey I have received from them has more than paid all I have spent on them the two years past. It has been from 30 to 40 lbs. per colony. This year does not seem to be a very good one for honey. We had but little white clover, and that is our chief crop, as we have no basswood any thing of the kind here. I have wintered each winter on summer stands at the east end of the

house, with rough boxes outside of hives, packed with chaff. I left in all the frames just as they were in summer, and entrance all open, with mats and brood-frames and chaff cushions on top of mats.

Oil City, Pa., Aug. 3, 1885.

H. C. FINCH.

HOW AN ABC SCHOLAR "ROLLS UP THE BARRELS OF FINE HORSEMINT HONEY."

I don't know that I can tell you why it is that I have for a long time wanted to write, thanking you as I feel I ought, for the many good things you have taught. When I was introduced to you in Dec., 1882, we received the sample copy of GLEANINGS, and for some time afterward I also thought I objected to the mixed matter in GLEANINGS. But after a better and more intimate acquaintance of three years, I want to say that any other GLEANINGS, than GLEANINGS as it is, would not be GLEANINGS at all. In greedily devouring, as it were, the "bee-talk" of GLEANINGS the first year, and its inimitable offspring, the ABC book, I could see queen-rearing, extractors, barrels of extracted honey, Italian bees, etc., as one sees objects in a dream; but through your teachings I have been enabled to see it all practically in my own apiary, and to roll up the barrels of fine horsemint honey, two, three, four, and five deep. Besides the enjoyment, or, as you say, "rare fun" of working with the bees, I have become a closer student of nature; and many beautiful and strange things have unfolded before me. "Myself and My Neighbors," and "Our Homes," have enabled me to see human nature in a different and better light, and to make our own duty plainer in our daily walk toward our "home above."

H. A. GOODRICH.

Massey, Tex., Aug. 24, 1885.

[Friend G., your letter makes me almost tremble in my shoes, as such letters have many times before, for fear I shall in some way prove unworthy of such very, very kind words; and all I can say at such times is, "May God help me to come even a little way toward deserving it all."]

[ADVERTISEMENT.]

The Largest Cabbage Growers in the World (W. M. Johnson & Co., of Chicago), use upwards of five thousand acres of land for growing cabbages. Last season they manufactured nineteen thousand six hundred barrels of sourkroot, besides shipping four hundred and sixty-seven carloads of cabbages to eastern cities. They use and recommend Tillinghast's Puget-Sound Cabbage Seeds. The disseminator of this renowned brand of seeds, Isaac F. Tillinghast, of La Plume, Pa., in order to introduce them into every county in the Union, has organized a Seed and Plant Growers' Association. One reliable party in each town in the Union is being enrolled as special agent, and is supplied with seeds in trade marked packages, and also instruction books which will enable any one to grow cabbage-plants successfully anywhere. Parties desiring seeds or plants, will, upon application to Mr. Tillinghast, be furnished with the addresses of agents nearest them from whom they may be obtained. Purchasers are thus saved unnecessary express charges, and assured of obtaining the best strain of cabbage seeds or plants which can be procured.

This association thus furnishes one man in each town—the appointed agent—a good cash-paying business in selling seeds and growing and supplying plants. There are still many excellent localities unoccupied, and any one so situated as to act as agent for this association should address Mr. Tillinghast as above, for particulars in regard to it.

Mr. Tillinghast has also just put upon the market a "Cabbage-Pest Powder" which is entirely harmless to the plant at any stage of its growth, and also harmless to persons eating them, yet the most effective destroyer of lice, fleas, and worms, which has ever been compounded. It retails at 24 cents per pound.

18d

LOOK HERE!

To introduce my strain of pure bright Italians, equal to any in the United States, I will offer for August, tested queens, \$1.00 each; extra fine, selected, \$1.50 each; one-frame nucleus, consisting of one extra select queen, one frame of brood, ½ lb. bees, for \$2.00. If you want any bees, send me your address on postal and I will send you sample by return mail. Beeswax or honey taken in exchange.

CONVENTION NOTICES.

The Maryland, Virginia, and West-Virginia Bee-keepers' Convention will meet at Hagerstown, Md., in the court house, on Wednesday, Oct. 21, 1885, at 10 A. M. By order of D. A. PIKE, Pres.

The N. J. and Eastern Bee-keepers' Association will hold their Semi-annual convention in Grand-Jury room of Court-House, in Trenton, N. J., on Thursday and Friday, Nov. 5 and 6, 1885, at 10 o'clock A. M. We extend a cordial welcome to all. W. M. B. TREADWELL, Sec.

The Western Bee-keepers' Association will hold its fourth annual meeting in Independence, Mo., Thursday and Friday, Oct. 10 and 11, 1885. The association will endeavor to make this the most interesting meeting yet held, and will spare no pains within its means to make it in every sense valuable to all. Several of our most prominent bee-keepers have signified their intention to be present. C. M. CRANDALL, Sec.

We have received the following from the Kentucky State Bee-keepers' Association:

Dear Sir and Bro.:—You are invited to meet with us in the State Bee-keepers' Society, in Walker Hall, Covington, Ky., on the 23d and 24th of September, 1885. This is expected to be the most interesting meeting ever held in the State. Rev. L. L. Langstroth, the father of American apiculture, and Mr. Charles Dadant, the great comb-foundation manufacturer, will meet with us, as well as many other noted apiarists. We hope to see you at the Convention. L. JOHNSON, President.

J. T. CONNLEY, Sec'y.

EXCHANGE DEPARTMENT.

Notices will be inserted under this head at one-half our usual rates. All ads. intended for this department must not exceed 5 lines, and you must say you want your ad. in this department, or we will not be responsible for any error.

WANTED.—In exchange for new varieties of strawberries and raspberries, Plymouth Rocks, Light Brahmas, Pekin Ducks, new varieties of potatoes, and small-fruit plants, cherry and quince trees. P. SUTTON, Exeter, Luz. Co., Pa. 16-23db

WANTED.—Extracted fall honey (buckwheat or goldenrod) in exchange for hives, sections, etc., either from my catalogue, or made to order. Will pay white-clover prices for a few hundred pounds. C. W. COSTELLO, Waterboro, York Co., Maine.

WANTED.—To exchange bees for small planer for wood, also one for iron. 18-19-20d HENRY PALMER, Hart, Mich.

WANTED.—To exchange for bees, 10,000 Mammoth-Cluster Raspberry-plants; \$1.00 per 100; \$6.00 per 1000; also 20,000 Strawberry-plants, Crescent Seedling, Cumberland Triumph, Sharpless, and Glendale; 75c per 100; \$4.00 per 1000. 18d W. J. HESSER, Plattsmouth, Neb.

WANTED.—To exchange No. 1 model printing-press, self-inker, chase 5x7½ inches, type and type-cases, for Italians or hybrid bees. 18-19d A. P. SHARPS, Exeter, Luzerne Co., Pa.

WANTED.—To exchange for well-ripened honey fit for winter stores, thoroughbred P. Rock fowls, pure Corbin strain; a Franz & Pope family knitting machine, almost new; a new model-maker's drill-lathe, eight-inch swing, two-foot bed. 18-19d M. FRANK TABER, Salem, Ohio.

WANTED.—To exchange hybrid bees and queens for fdn., fdm., mill, honey-extractor, saw-mandrel, or others. Will exchange Blue-Ridge Raspberry-plants for fdn. Correspondence solicited. 18tdb JOHN W. MARTIN, Greenwood Depot, Alb. Co., Va.

FULL COLONIES FOR \$3.00.

R. HYDE, Alderly, Wis.

W. Z. HUTCHINSON,

ROGERSVILLE, GENESEE CO., MICH.,

Can still furnish Italian queens, bred from the best of mothers, and reared in full colonies. Single queen, \$1.00; six for \$5.00; twelve or more, 75 cents each. Tested queens, \$2.00 each. Make money orders payable at Flint. 18tdb

DADANT'S FOUNDATION FACTORY, WHOLESALE AND RETAIL. See advertisement in another column. 3tdf

JOB LOT OF WIRE CLOTH

AT GREATLY REDUCED PRICES.

SECOND QUALITY WIRE CLOTH AT 1½ CTS. PER SQUARE FT.

SOME OF THE LISTS TO WHICH THIS WIRE CLOTH CAN BE APPLIED.

This wire cloth is second quality. It will answer nicely for covering doors and windows, to keep out flies; for covering bee-hives and cages for shipping bees; making sieves for sifting seeds, etc. Number of Square Feet contained in each Roll Respectively.

Inches Wide.	No. of Rolls.
10 3/4	3 rolls of 75, 72 s. f.
12 1/2	2 rolls, 100 s. f. each.
20	3 rolls of 166 s. f. each.
22	4 rolls of 181, 1 of 169 s. f.
24	6 rolls of 200, 1 of 180, and 1 of 139 s. f.
36 1/2	23 rolls of 217, 38 of 216, 2 of 195, 1 of 156, 1 of 122, 2 of 215, 1 of 210 s. f.
28	16 1/2 rolls of 223, and 2 of 224 s. f.
34 1/2	7 1/2 rolls of 281 s. f.
36	
38 3/4	28 rolls of 316, 3 of 285, 2 of 317, 1 each of 190, 632, 136, and 215 s. f.
42	1 roll of 245 s. f.
44	2 rolls of 366, 1 of 318 s. f.
46	1 roll of 152 s. f.
48 1/2	10 rolls of 400, 1 of 200, 1 of 50 s. f.

FIRST QUALITY WIRE CLOTH AT 1½ CTS. PER SQUARE FT.

The following is first quality, and is worth 1½ cts. per square foot. It can be used for any purpose for which wire cloth is ordinarily used; and even at 1½ cts. per sq. ft. it is far below the prices usually charged at hardware and furnishing stores, as you will ascertain by making inquiry. We were able to secure this very low price by buying a quantity of over one thousand dollars' worth.

Inches Wide.	No. of Rolls.
10 3/4	1 roll of 155 s. f.
22	1 roll each of 83, 143, 92 s. f.
24 1/2	43 rolls of 200 sq. ft. each; 1 each of 80, 95, 120, 168, 190, 250, 150, 140 sq. ft.
26 3/8	rolls of 216 sq. ft. each; 1 each of 195, 195, 200, 200, 201, 227, 201, 204 sq. ft.
28 1/2	rolls of 223, 6 of 224, 3 of 219, 8 of 227, 7 of 224, 2 of 219, 1 of 117 sq. ft.; 1 each of 70, 210, 245, 257, 240, 215, 110, 93, 82 sq. ft.
30 3/8	rolls of 230 sq. ft.; 1 each of 23, 137, 115, 117, 125, 125, 230, 225, 227, 227, 235, 275, 240, 157 sq. ft.
32 1/2	1 of 206, 7 of 206, 2 of 233 square ft.; 1 each of 233, 251, 117 sq. ft.
34 1/2	rolls of 283 sq. ft. each; 1 each of 62, 113, 198 sq. ft.
36 1/2	rolls of 200 sq. ft. each; 2 of 72, 1 each of 288, 150, 279, 285 sq. ft.
38 1/2	roll each of 200 and 316 sq. ft.
40 1/2	roll of 233 square feet.
42 1/2	roll of 350 square feet.
46 1/2	roll of 122 square feet.

A. I. ROOT, Medina, Ohio.

POTATO-BOXES

(TERRY'S).

These are made of basswood, lined with galvanized iron. The galvanized iron gives strength, and the basswood strength and lightness. These hold exactly a bushel when level full, and may be piled one on top of another. Although they are made especially for potatoes, they can be used for fruit, vegetables, picking up stones on the farm, and a thousand other purposes. When piled one above the other, they protect the contents from the sun and rain; and from their shape a great many more bushels can be set into a wagon than where baskets are used. They are also much more substantial than baskets.

Price 25 c each; 10, \$2.25; 100, \$20.00. In the flat, including nails and galvanized iron, \$1.75 for 10; 100, \$16.50; 1000, \$150. A. I. ROOT, Medina, O.

WANTED.—To exchange salt mackerel in 20-lb. pails, for good extracted honey.

E. E. LING, 11 Silver St., Portland, Maine.

WANTED.—To exchange one lamp-nursery, scarcely used, and one heavy circular-saw mandrel, 1 1/2-16-inch shaft, in good order, for any thing useful to a bee-keeper.

1914b J. A. GREEN, Dayton, Ill.

Names of responsible parties will be inserted in any of the following departments, at a uniform price of 20 cents each insertion, or \$2.00 per year.

\$1.00 Queens.

Names inserted in this department the first time without charge. After, 20c each insertion, or \$2.00 per year.

Those whose names appear below agree to furnish Italian queens for \$1.00 each, under the following conditions: No guarantee is to be assumed of purity, or anything of the kind, only that the queen be reared from a choice, pure mother, and had commenced to lay when they were shipped. They also agree to return the money at any time when customers become impatient of such delay as may be unavoidable. Bear in mind, that he who sends the best queens, put up most neatly and most securely, will probably receive the most orders. Special rates for warranted and tested queens, furnished on application to any of the parties. Names with *, use an imported queen-mother. If the queen arrives dead, notify us and we will send you another. Probably none will besent for \$1.00 before July 1st, or after Nov. 11 wanted sooner, or later, see rates in price list.

EXCHANGE DEPARTMENT.

Notices will be inserted under this head at one-half our usual rates. All ads intended for this department must not exceed 5 lines, and you must say you want your ad in this department, or we will not be responsible for any error.

WANTED.—In exchange for new varieties of strawberries and raspberries, Plymouth Rocks, Light Brahmas, Pekin Ducks, new varieties of potatoes, and small-fruit plants, cherry and quince trees. P. SUTTON, Exeter, Luz. Co., Pa. 16-23db

WANTED.—Extracted fall honey (buckwheat or goldenrod) in exchange for hives, sections, etc., either from my catalogue, or made to order. Will pay white-clover prices for a few hundred pounds. C. W. COSTELLO, Waterboro, York Co., Maine.

WANTED.—To exchange bees for small planer for wood, also one for planer. 18-19-20d HENRY PALMER, Hart, Mich.

WANTED.—To exchange for bees, 10,000 Mammoth-Cluster Raspberry-plants; \$4.00 per 100; \$6.00 per 1000; also 20,000 Strawberry-plants, Crescent Seedling, Cumberland Triumph, Sharpless, and Glendale; 75c per 100; \$4.00 per 1000. 18d W. J. HESSER, Plattsmouth, Neb.

WANTED.—To exchange for well-ripened honey fit for winter stores, thoroughbred P. Rock fowls, pure Corbin strain; a Franz & Pope family knitting-machine, almost new; a new model-maker's drill-lathe, eight-inch swing, two-foot bed. 18-19d M. FRANK TABER, Salem, Ohio.

WANTED.—To exchange hybrid bees and queens for fdn., fdu. mill, honey-extractor, saw-mandrel, or offers. Will exchange Blue Ridge Raspberry-plants for fdu. Correspondence solicited. 1811db JOWN W. MARTIN, Greenwood Depot, Alb. Co., Va.

WANTED.—To exchange Syrio-Italian and Red-Clover Italian bees and hybrids in L. and Simplicity hives, for foot-power saw in good order (Barnes preferred), incubator, or printing-press. 18d J. SINGLETON, 34 Public Square, Cleveland, O.

WANTED.—To exchange thoroughbred late spring Brown Leghorn chickens or cockerels for Light or Dark Brahmas, Plymouth Rocks, Langshans, Partridge Cochins, White Leghorns, or others. Must be pure. Correspondence solicited. 18d G. A. FARRAND, Rockport, Cuy. Co., O.

Hive Manufacturers.

Who agree to make such hives, and at the prices named, as those described on our circular.

HONEY COLUMN.

CITY MARKETS.

KANSAS CITY.—*Honey.*—We now report a very firm market, with some advances in prices, though the trade takes hold "gingerly" as yet, and squealing like pigs when the advance is quoted them. We are now holding for 16¢/17c on fancy white 1-lb. sections; 15¢/16c for 2-lb., and 12¢/13c for California. We are short on fancy 1-lb. sections, and would suggest this as a good time to ship and realize good prices. Extracted, a little firmer, at about same prices; viz., Miss. La., and Tex., 4¢/6c.; Cal., 7¢/8c. White clover, 7¢/8. *Beeswax.*—Unchanged, 20¢/25, according to quality. **CLEMONS, CLOON & Co.**
Cor. Fourth & Walnut Sts., Kansas City, Mo.

BOSTON.—*Honey.*—We have received quite a large stock of honey, mostly from Vermont, and the quality is very fine. We are doing the best we can to keep the price up, where bee-keepers can get something for their honey. One of the largest producers sold his entire crop at a very low price, and it is being sold here at a price that would give the bee-keeper nothing. We still hold our price, 16¢/18c for 1 pound, 14¢/16c for 2 pounds. Extracted, 6¢/8c. *Beeswax*, 30c. **BLAKE & RIPLEY,**
Sept. 21, 1885. 57 Chatham St., Boston, Mass.

CINCINNATI.—*Honey.*—No change whatever in the honey or beeswax market since my last.
Sept. 25, 1885. **CHAS. F. MUTH,**
Cincinnati, Ohio.

CHICAGO.—*Honey.*—Honey is coming forward in amounts about equal to the demand. White comb honey in one-pound frames, or about, brings 15¢/16c when put up in the small crate, and frames all scraped clean, and put in so that it won't chafe. Buckwheat or dark comb is about unsalable, extracted selling from 5¢/8c according to quality.
Beeswax, 23¢/25c. **R. A. BURNETT,**
Sept. 24, 1885. 161 So. Water St., Chicago, Ill.

CLEVELAND.—*Honey.*—Honey seems to be unusually dull for this time of year. It moves very slowly at 14¢/15 cts. for best 1-lb. sections. Old honey at 10¢/12c. shares the same fate. Extracted is dull at 7¢/8. *Beeswax*, 22c. **A. C. KENDEL,**
Sept. 21, 1885. 115 Ontario St., Cleveland, O.

MILWAUKEE.—*Honey.*—This market is in good shape for shipments of honey. Choice white 1-lb. sections salable at 17¢/18c. Dark, not in demand. Price nominally, 12½¢/15c. Extracted, white, in 100-lb. kegs, in good demand at 8c. *Beeswax*, dull. Quotable at 25¢/28c. **A. V. BISHOP,**
Sept. 23. 142 W. Water St., Milwaukee, Wis.

DETROIT.—*Honey.*—One-pound sections are selling readily at 16¢/17 c. **A. B. WEED,**
Sept. 21, 1885. 407 Woodward Ave., Detroit, Mich.

INDIANAPOLIS.—*Honey.*—We are trying to build up an exclusive honey trade. Being also producers, it gives us some advantage. We are disposing of lots on commission, and would be pleased to hear from those who would like to try our market.
Sept. 12, 1885. **FRANK L. DOUGHERTY,**
532 East Washington Street, Indianapolis, Ind.

FOR SALE.—1000 lbs. of well-ripened linden extracted honey, in 55-lb. iron jacket, tin cans, at 7 cts. per lb., and A. I. Root's price of can. Will ship in 40-lb. tin cans, if desired, purchaser paying for cans.
MRS. NELLIE M. OLSEN,
19d Nashotah, Waukesha Co., Wisconsin.

FOR SALE.—8600 lbs. of extracted basswood honey in ¼ bbls.; net weight 185 lbs. I will take 8 cts., barrel thrown in.
JOHN H. MARTIN,
Hartford, N. Y.

FOR SALE.—Extracted clover and basswood honey in ten-gallon kegs at 8c per lb. I will throw in kegs, and deliver on board cars free of charge.
M. ISBELL, Norwich, N. Y.

CONVENTION NOTICE.—The next annual meeting of the Northern Michigan Bee-Keepers' Society will be held at the council rooms in Sheridan, Oct. 22 and 23, 1885. A cordial invitation is extended to all.
F. A. PALMER, Sec.

❖ FOR SALE. ❖

I WILL SELL

Full Swarms of Pure Italian Bees
DURING THIS MONTH FOR
Four Dollars Each.

They are in 10-frame Simplicity hives, and in good winter shape. Ready to ship now. Send money by registered letter. Address

M. R. NICHOLS,
1914th Weaver's Corners, Huron Co., O.

Reduction in Prices of the
PASTEBOARD BOXES
FOR ONE-POUND SECTIONS OF
COMB HONEY.

THIS box has a bit of "red tape" attached to it to carry it by. It makes a safe package for a single section of honey for the consumer to carry, or it can be packed in a trunk, if he wants. It can be opened in an instant. The price of the box is 2 cts. each, set up; in the flat, 15 cts. for 10; package of 25, 30 cts.; \$1.00 per 100; or \$9.00 per 1000; 10,00, \$90. If wanted by mail, add \$1.00 per hundred for postage. Colored lithograph labels for putting on the sides, two kinds, one for each side, \$3.00 per 1000. A package of 25, labeled on both sides, as above, 50 cts. By mail, 30 cts. more. They can be sold, labeled on one side or both sides, of course. We have only one size in stock, for Simplicity sections. Sample by mail, with a label on each side, 5 cts. If you want them shipped in the flat, labels already pasted on, the price will be ten cents per hundred for putting them on.

Your name and address, and the kind of honey, may be printed on these labels, the same as other labels. The charge for so doing will be 30 cts. per per 100; 250, 50 cts.; 500, 75 cts.; 1000, \$1.00.

A. I. ROOT, Medina, Ohio.

HYDROMETERS FOR TESTING HONEY.

We have succeeded in getting a beautiful little instrument, all of glass, that will indicate the density of honey or maple syrup, or any kind of syrup, by simply dropping it into the liquid. I am greatly surprised that we can furnish so beautiful an instrument for so small a sum of money. Price 35c. By mail, 10c extra. Per 10, \$3.00; per 100, \$25.00.
A. I. ROOT, MEDINA, OHIO.

WANTED. After Nov. 1st, position in some Southern State as apiarist. For terms and reference address
CHAS. R. THOMPSON, FORT OMAHA, NEB. 19d

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they want to dispose of, we will insert notices free of charge, as below. We do this because there is hardly value enough to these queens to pay for buying them up and keeping them in stock, and yet it is often times quite an accommodation to those who can not afford higher priced ones.

Hybrid queens, 50 cts. each; black queens, 25 cts. each; from Aug. 1st to Oct. 1st, safe arrival guaranteed. **G. K. RAUDENBUSH, Reading, Berks Co., Pa.**

Vol. XIII.

OCT. 1, 1885.

No. 19.

TERMS: \$1.00 PER ANNUM, IN ADVANCE.
2 Copies for \$1.90; 3 for \$2.75; 5 for \$4.00.
10 or more, 75 cts. each. Single Number,
10 cts. Additions to clubs may be made
at club rates. Above are to be sent
to ONE POSTOFFICE.

Established in 1873.

PUBLISHED SEMI-MONTHLY BY

A. I. ROOT, MEDINA, OHIO.

Clubs to different postoffices, NOT LESS
than 50 cts. each. Sent postpaid, in the
U. S. and Canada. To all other coun-
tries of the Universal Postal Union, 18c
per year extra. To all countries NOT of
the U. P. U., 42c per year extra.

NOTES FROM THE BANNER APIARY.

NO. 70.

DRONE COMB AND OLD QUEENS.

YOU ask, friend Root, if we did not have some drone comb built, when we allowed the bees to build their own comb in the brood-nest. Haven't you forgotten how this matter was discussed the last time this subject was up—how Bro. Doolittle took it up and enlarged upon it, illustrated, and explained? Before bees swarm they desire drones, and will build drone comb; after they have swarmed they have no desire for drones, and do not build drone comb, *unless* they have an old queen that they are intending to supersede. It is possible that, were the bees allowed a large brood-nest, they would build in it some store comb, but when given only five frames in the brood-nest no drone comb has been built for us, *unless* the queen was an old one. This season, in our apiary, about one comb in twenty-five, built by the bees, is drone comb, and in every case the queen was an old one. Here is a letter upon this subject, that of dispensing with foundation, from our old friend Dr. Whiting:

East Saginaw, Mich., Aug. 31, 1885.

W. Z. HUTCHINSON, Dear Sir:—I have just finished reading your article in Sept. GLEANINGS, and most heartily indorse your plan of getting comb honey from new swarms. My bees put the most honey in the sections when they have to build their own brood-combs. They do next best on foundation, and the poorest on drawn combs. If there is an empty cell to put honey in, the bees will deposit the honey taken with them when they swarm, and there it remains. If they are obliged to build comb, the queen is ready to put in the eggs as soon as the cells are deep enough, and that stops the deposit of

honey below the first eggs that are laid. You will get the most wax in the openings in your queen-excluding honey-boards in a poor season, and with weak swarms more than with strong ones.

L. C. WHITING.

When talking the matter over with Mr. R. L. Taylor, at our State Fair, he said that he had hived two or three swarms upon empty frames, and he could not see but that they did just as well as those given foundation. 8—W. Z. HUTCHINSON, 70—100.

Rogersville, Mich., Sept. 21, 1885.

OUR OWN APIARY.

REPORTED BY ERNEST.

AS there is some inquiry in regard to "Our Own Apiary," and a number of the friends have requested to have this department renewed, I hope our patrons will excuse me if I make an attempt at it. There are some very obvious reasons why it should be recommenced. By virtue of our position we are supposed to have a sort of experimental station, where all the modern appliances are to be thoroughly tested, and a report of the same to be given from time to time. It is true, a report of the more important things have been given occasionally; but I feel assured our A B C scholars would be glad to know just what we are doing in our *own* apiary, that they may execute their own plans accordingly.

CARNIOLAN BEES.

I have just to-day examined that Carniolan swarm. About four-fifths of the bees are now of the new race. It seemed to me, as I looked at whole frames of the bees, that although the difference between them and the common blacks is not very

great, yet there are some decisive marks by which we may distinguish them. In the first place, they are larger than the native bees, and their white or whitish-gray rings of fuzz are quite clearly defined. In fact, they are much like the Italians, with the exception that, where we should expect the golden color, we see a deep jet black; but I do not see any blued-steel color, as some of the friends have claimed for them. As has been said, they seem very gentle, and, in point of disposition, very much like the Italians. While looking at them preparatory to closing the hive, I was forced to think they lacked good grit. You will bear in mind, that there were a few Italians still left in this hive. Well, as I stood over the swarm there were (as is apt to be the case at this time of the year) about six or eight robbers trying to enter the top of the swarm. While the few remaining Italians vigorously repelled every invasion, and stood in readiness for every robber, not one Carniolan did I see show any disposition at defense. In this respect they are like the blacks. I am aware that this is not a test case; but, let others report upon this point.

The Carniolans are said to be handsome. Well, yes; they are handsome with their light gray rings of fuzz; but in my opinion the old standby, Italians, with their golden-yellow bands varied with the same light-gray fuzz, are still handsomer.

THE CLARK SMOKER WITHOUT A VALVE.

One or two of the friends have written that a Clark smoker without a valve worked just as well. It occurred to me that it *might* work, though I feared that soot would collect and fill the blast tube, since the smoke would have to enter the bellows before being blown out. I was not surprised to find that such was the case. Not only did the smoke enter the bellows, but heat and cinders, making the two pieces of board quite hot. Of course, the ultimate result would be that the leather would soon have holes burned through. Where one has only a few hives, and is not obliged to make a "vigorous snudge," a smoker of this kind might answer tolerably well for a while.

THAT BEE DISEASE WHICH HAS NO NAME.

Several days ago our apiarist called my attention to a swarm of bees that were diseased, and which the healthy bees were carrying out. These bees were tugged out, one after another, and left to die, like drones in a dearth of honey. They manifested that peculiar twitching motion; their abdomens were black and shiny, and considerably swollen from accumulated matter. They seemed very much like bees affected with dysentery. We came to the conclusion from the symptoms that it was the disease without a name, mentioned in the A B C book, page 69. On showing it to "A. I." he pronounced it the veritable disease. It is the first case that we have had since the one mentioned in the A B C, although reports seem to indicate that in some localities it is quite prevalent, especially in the last two seasons. Perhaps I should mention that the mother of these bees was not a queen of our own raising, but one from the South. She was sold Aug. 28th, and in consequence the swarm is on the road to recovery. If any of the friends received a queen from us about this time, whose bees show the symptoms mentioned above, we will make her good upon being notified.

THE BEE-TENT WITH A HOLE IN THE TOP.

A few days ago we had a slight touch of robbing, occasioned by a chaff-hive cover which was not perfectly bee-tight (it's fixed now). Well, that tent

with the hole in the top was placed over the hive, as mentioned on page 540. The result was almost astonishing. As each bee had bumped his head against the top several times, and had popped out of said hole, he seemingly went home in disgust; and, as far as we could discover, stayed there. It would seem that we ought to manufacture these tents with this opening; but I am afraid some friend, not knowing what the hole was for, would complain, saying his tent was "holy," so we will send them out as before, and the purchaser can make the hole himself. The opening in our tent is about 4 inches in diameter, right in the peak.

PREPARING FOR WINTER.

Our apiarist, for a week or so back, has been getting the bees ready for winter. All superfluous combs partly filled with honey are placed over the brood-nest. The object of this is to secure nothing but full combs of sealed stores for the bees. After the combs are emptied they are removed, and kept till next winter. Caution has to be exercised here, or the robbers, smelling the honey in the upper story, will get at the combs unless the covers are absolutely bee-tight. Doubling up has already commenced, and every colony is examined to see that it shall have sufficient stores. If the queen does not lay she is given an empty frame in the center of the brood-nest, and the colony is fed. This is to secure young bees for winter.

ERNEST R. ROOT.

DOOLITTLE'S REPORT.

DO BEES GET HONEY FROM THE MAPLE, OR IS IT ONLY POLLEN?

WHEN I took an inventory of my bees on May 20, 1885, I found that I had, after sales and losses, 25 good to fair, 15 rather weak, and 10 very weak colonies, making 50 in all, left out of 80 in the fall of 1884. Still having further calls for bees, and having much extra work on hand, I again reduced my stock by sales, disposing of five of the best and five of the rather light ones, which left me but 40 to commence the season with, ten of which were so weak on June 1st that they had brood in only one and two combs. These ten weak colonies, and three of those next weakest, were set apart for queen-rearing, thus leaving but 27 to be devoted to the production of honey. The spring was quite unfavorable until the willows and hard maple blossomed, at which time we had some pleasant weather, which was improved by the bees in gathering pollen from the maple, and honey from the willow. This gave all the good colonies a nice start, but the weaker ones only held their own till after the 10th of June, at which time we again had warm weather, and all began to be prosperous.

Why I speak of pollen from the maple, and honey from the willow, as above, is that many seem to suppose that hard maple yields much honey certain years, while all of my observations show that it yields comparatively nothing but pollen. I do not say that such is the case in all localities, but I am inclined to think that it may be. We are all apt to jump at conclusions, so when we hear the merry hum of the bees in the maple-trees, and see at the same time that honey is being stored in the hive, there is nothing more natural than to suppose that the honey came from that source. But, to be sure such is the case, we need a little more proof, which, in my case, after being applied gave the credit to

the willow for the honey, and not to the maple. If any person has maple, with no willow within five miles of him, the conclusion that the honey came from maple would be better founded than when there was an abundance of both, and still the conclusion might be wrong, as the proof by killing a bee might show. When I desire to know just what a bee is getting from any plant or tree, I watch it for some length of time till it has visited a number of flowers, when I catch and kill it, after which I remove its honey-sack, which tells me at once if said bee is getting honey from the flower it is at work upon; for if the sack is empty it says no honey. Thus I find the honey-sack of bees at work on hard-maple blossoms empty, while their pollen-baskets are filled with pollen; a bee thus caught on the golden willow shows a sack full of honey, with no pollen in its baskets. Is not this better proof than the first supposition cited? These facts are of value when we are deciding what to plant for honey. But, to return to the report.

Bees got scarcely a living from raspberry; but, thanks to our farmers, a few acres of alsike clover had been sown the season previous, which, together with the little white clover along the roadside, gave the bees a plenty for brood-rearing, while some of the strongest stored a little in the sections from the same. However, but very few sections were completed—the main benefit being in helping in brood-rearing and giving a start in some of the sections, which was continued during the basswood flow.

Basswood opened July 14th, but the bees got very little from it until the 18th, at which time work began in earnest, and lasted for 12 days, which, with two days of winding up, ended the honey season for 1885; for since this the bees have got nothing except a little for brood-rearing during a few warm days about the 10th of August.

After having my honey all crated and weighed, I find the result of the season to be as follows: Comb honey, 252 lbs.; extracted, 188 lbs., or 3160 pounds in all. This divided by 27, the number of colonies worked for honey, gives an average of 117 lbs. per colony, nearly all of which was comb honey. I have at date, 90 colonies and 30 nuclei, but I shall double down to less than 100 for winter. I am selling a little honey about home at 15 cts. for comb and 10 cts. for extracted, but I presume I shall send the most of it to be sold on commission, as those talking about buying offer very low prices. F. I. Sage & Son, of Weathersfield, Conn., have bought several crops in this (Onondaga) and Cortland Counties, at from 11 to 13 cents per lb., but I am hardly willing to sell at those figures. One thing recommends their plan of buying to bee-keepers, however, which is that they come to your railroad station, accept and weigh the honey there, and pay "spot" cash for it. Thus the bee-keeper is relieved of all worry and bother which naturally arises where honey is shipped on commission, or paid for on delivery in any of the large cities.

Borodino, N. Y., Sept. 16, 1885. G. M. DOOLITTLE.

Friend D., the point you make is a good one, that we are not sure that bees get honey from any plant or tree, simply because we see them busily at work on it, and honey is coming into the hives. It still seems to me, however, that bees do get much honey from the maples here, although I have no better reason to give than that maple-trees

are roaring with bees, while an abundance of honey is coming in, having a strong flavor of maple syrup. There are very few willows in our vicinity, and I have never noticed bees on them, what there are, unless it be an occasional willow, such as we sometimes find in dooryards, as an ornamental plant. However, I am going to test the matter, in the way you suggest, when I see bees working on the maples again.—I am glad to know that there are large honey-buyers who make a practice of going right to the producers, and shipping it at their own expense.

RIPE EXTRACTED HONEY.

HEDDON'S PLAN TO GET IT.

As promised, I will now endeavor to outline the plan by which I produce such honey as brings a favorable testimonial from about 2, of my customers (most of whom are bee-keepers, and good judges of honey), and complaints from none; such honey as I have just shipped you.

Before beginning a description of my plain simple method of working, let me first call your attention to the fact, that although our basswood honey stands first in brightness of color, and second to none in the comb, it is beginning to be graded as second to white clover, when extracted, by some of our dealers and consumers. The query naturally arises, "Why this difference in grading, between these two kinds of honey in the comb, and extracted?" I believe the reason to be based upon the fact, that many of us have extracted our honey before it was *dead ripe*; and where this system is practiced, basswood honey is apt to be taken out in the least ripe condition, for the reason that clover honey is usually riper in the flowers, and comes in slower, allowing the bees to evaporate it more, before the apiarist thinks he sees the necessity for emptying his combs.

I suppose nearly all readers know what is meant by "ripe" honey. We call honey "ripe" when it has that smooth, oily, and thick consistency of old comb honey that has been in the hive some considerable time. It is then free from that sharp "twang," or cutting sensation in the throat, which nearly all consumers dislike. This undoubtedly is caused by a slight development of bacteria, which are always present, we are told, in cases of fermentation. It may properly be said, that this raw, "twangy" honey, is more or less infested with these germs, or tending toward fermentation, or souring. The interior of the hive, together with the system of digesting, heating, and ventilating, by the bees, seems to be the best place yet known in which to destroy these germs, leaving the honey thick, rich, oily, or smooth; in other words, *ripe*.

I will tell you how we have worked to produce our honey, which we consider thoroughly ripe.

Our last winter's loss of about 350 colonies left us with a large number of combs to cover with bees. We had on hand and nailed up, about 600 supers the full size of our 8 L. frame hive. When our hives were well filled with brood, and the surplus season opened, we put on our honey-board, and one of these supers containing eight brood-combs. As soon as these eight combs were pretty well filled, and the bees commenced capping them at the top,

this super was raised up, and another empty one, just like it, placed under it, upon the tiering-up plan—the grandest principle connected with the production of comb or extracted honey.

Experienced bee-keepers will at once suspect the fact that the lifting of this super, and introduction of an empty one under it, considerably checked the capping of the honey it contained, while it did not materially retard the evaporation or ripening process. During the beginning of the clover and basswood bloom, at that time when the nectar is thinnest, we frequently used three of these large supers on a hive, for a short time, before we removed the upper one and extracted it. When we came to extract we found our honey thoroughly ripened; yet the combs containing it, capped over only where they were thickest, and you will remember that it is very speedy and pleasant work to uncapp combs that are capped over only where the cells are most elongated, leaving you no hollow places to reach into with the uncapping-knife.

After our honey is extracted we leave it in large tanks till it is thoroughly settled; *i. e.*, all air-bubbles, bits of comb, etc., have risen to the top, when we draw it off at the bottom into our 50 and 100 lb. kegs; bung them up tightly and put them in a cool place. This thoroughly ripened honey will not candy or granulate nearly as quickly as that which is unripe, or of less body, containing, as it does, more water. We also store a considerable quantity in 50-lb. tin cans, and also about 500 one-gallon stone crocks, which we keep till cool weather, when all honey begins to granulate; and when our customers ask for "clear honey" we set these crocks and cans in our large tank containing water, and placed upon the stove, and slowly and carefully heat it till it is again all liquefied, when we pour it into one of the tanks, give it time to settle, and while yet warm enough to flow readily, draw it into the kegs and bung it tightly, when it is ready to ship. This heating process, properly done, rather than being an injury to either color or flavor, is an additional help to perfecting the quality of honey.

It has recently been discovered, I see by GLEANINGS, that some peculiar varieties of honey that are almost poisonous when unripe, are quite the reverse when thoroughly ripened. I feel quite sure that all honey is much more wholesome when completely ripened; and it is only such honey that creates an increasing demand.

Father Langstroth tells us that basswood honey contains most of the nutritious oils which make it pre-eminently adapted to persons of weak lungs or consumptive tendencies. He tells us how Mrs. L. was saved from premature death by consumption, by way of a systematized basswood honey diet. He has just ordered a 100-lb. keg from us.

I claim nothing original or new in the above, except, perhaps, a trifle by way of detail and manipulation. I gave it to more thoroughly impress upon the minds of our bee-keepers the importance of the system which is so ably formulated in friend Dant's little pamphlet on the subject. In ordinary cases I should, like friend D., use shallower supers. Last spring I had but 120 colonies left; but I had faith. I paid out \$7.00 for 124 more colonies, in all sorts of nearly worthless hives. By modern transferring they are now in our eight-frame L. hives, numbering 450, and though the unprecedentedly cold weather utterly destroyed our August crop, we got at least ten tons from clover and basswood;

and now the returning warmth is filling up our brood-chambers with goldenrod and aster honey. Thus our faith and pluck have been rewarded.

Dowagiac, Mich.

JAMES HEDDON.

Friend H., I entirely agree with what you say about ripe honey, although there are some of the friends, and, if I mistake not, Prof. Cook among the number, who claim that basswood honey is fit for the market if extracted before being sealed up at all, without the ripening process. Another advantage of your plan of getting the honey thoroughly ripened is, that you can secure pretty nearly if not quite the entire crop before you go at the extracting business at all. Of course, you may have to do your extracting at a time when honey has ceased to be gathered, and at such a time you will have to take very great precautions against robbers; but for all that, I think it is the better way. The nicest and best-ripened honey that I remember to have ever tasted was left on the hives until so late in the fall we were obliged to remove the combs from the hives by moonlight, to avoid disturbance from the robbers. We managed it easily, taking combs out and putting them back almost without a bee taking wing. The honey would hardly be recognized as basswood honey, the flavor was so ripe and complete, if that is the proper word.

A CAVE FOR WINTERING BEES; HOW TO MAKE ONE.

IS IT ADVISABLE TO TRY TO CONSTRUCT CAVES WHERE THEY ARE NOT TO BE FOUND NATURALLY?

SEVERAL have recommended a cave to winter bees in. Will not you or some one who has built one tell us just how it is done, telling especially how the roof is made? Our bees are storing honey very fast now from fall flowers.

Muscatine, Ia., Sept. 21, 1885.

J. T. GODDARD.

Friend G., I gave a very full description of how to build a cave, in the December No. of GLEANINGS for 1871—just eleven years ago, you see. Since that time a good many have used such caves, and some prefer them—among them, if I am not mistaken, Mr. L. C. Root, author of "Quinby's New Bee-Keeping." These caves are mostly used, however, where long cold winters are the rule. In our variable climate we have mostly discarded them. A cave for wintering can be built easiest in a side hill, for then there is no trouble about drainage. The room for the bees should be covered with a sufficient quantity of dirt to prevent frost from getting through; and over this dirt I would have a shingle roof. If you don't, heavy storms will be quite apt to get through and make it wet inside. A shingle roof will keep the dirt dry, which makes it a better non-conductor of frost. You will have to have a pretty strong framework to support this body of dirt; and another trouble comes in here, for when this framework begins to decay there is danger of your cave coming down on the bees, and possibly on yourself. Arching it over with brick or stone would do, but this would be much more expensive than having a building overhead—or, in other words, using an ordi-

nary cellar. If you are in a locality where a cave can be cut in a tolerably soft rock, you are, of course, all right; and in some cases I presume natural caves would answer an excellent purpose.

BEES BY THE POUND, FROM LOUISIANA TO NEW YORK.

HOW IT TURNED OUT.

IN the fall of 1884 I had a genuine Florida fever. The fever was induced by a young gentleman who was spending a few months' vacation at a summer resort a few miles from me, and who spends a greater portion of the year in Florida attending his orange-groves. This gentleman became interested in my apiary, and caught the bee fever, and offered me a very good salary to spend a few months with him, and set him up in the bee-business by establishing an apiary in his Florida home; but circumstances compelled me to stay in my Northern home. It was my plan, had I been at liberty to accept his offer, to take some of my best Italian bees south and rear queens and bees, and ship north by the pound early in the spring.

Having an apiary of over 50 swarms in an adjoining town, and losing quite a number of colonies during the winter, I thought it a good chance to try my Florida scheme. But instead of myself sitting under the orange-trees and receiving money from the north for bees, the experiment was against myself. Another man under the orange-trees must ship me the bees to stock up my apiary.

In March I commenced correspondence with parties in Florida; but our orange-grove bee-men did not have bees to sell by the pound, so I turned my affections and attentions to the man on the sugar plantations of Louisiana, and found a man who was willing to send bees by the pound. My trade was for 100 lbs. of bees and a number of queens, to be delivered the first week in May; but owing to cold weather in the South I did not receive my first shipment until the 25th of May; 30 lbs. were sent in this lot, put up in 2-lb. packages, and upon arrival I found fully one-half of the bees dead. In two cages every bee was dead; in several others, from one-half to two-thirds were dead, and only in two or three cages were the bees in good condition. In one cage there were less than a dozen dead bees.

This first shipment had quite an effect upon my Florida fever. It did not run so high. I wrote my shipper the condition of the bees upon arrival. The cages were 5½×5½, and 13½ inches in length. The candy was placed in two sections, flat in the bottom of the cages. Just as soon as a bee died it fell into the candy and stuck there; and as soon as enough died to cover the candy, the rest had to "root, hog, or die;" and as they didn't know how to "root," they died.

The next lot of 30 lbs. was put up in 5 lb. lots, in 4-frame-nuclei boxes, with combs for them to cluster and feel at home upon. I was assured that bees so shipped had been put through long distances, and had arrived in fine condition. My Florida fever began to rage again, and orange-groves appeared in my night visions.

On the 9th of June this lot arrived, and my Florida fever received such a shock that it has not returned since. The bees were in a worse condition than the first lot, and showed signs of very rough handling.

The candy was in the bottom, like the first lot; and in the cages where the bees were all dead, but a small portion had been eaten; and though the combs were wired L. frames, they were melted down; and comb, bees, and candy, were in a filthy, sticky mass in the bottom. Honey was oozing out from all sides of the cage. Smothering was very evidently the cause of death, and there were but a few pounds of live bees left in the whole lot. The queens to go with these pounds were sent by mail, and nearly all of these arrived in good condition.

The nuclei formed from these weary, dismayed, forlorn surviving travelers brightened up in a few days, and those that arrived upon the 25th of May were put to their level best; and when our bountiful harvest from basswood came they stored a paying amount of honey; and it is safe to say, had my 100 lbs. come to hand by the middle of May in the two-pound lots agreed upon, and in good condition, they would have given me fully 5000 lbs. of basswood honey. Of course, I could not ask the shipper to pay for this prospective honey. He sent me several extra queens, and promises to pay all express charges on all that are dead upon any lots I may order in the future. Our trade was amicably settled, but I do not feel like hearing the subject of experiments, especially unsuccessful ones. My actual damages would read something like this:

Loss of 5000 lbs. of honey @ 8c.	\$ 400
Going to R. R. station 6 miles, several journeys.	20
Distress of mind at not finding bees there.	1000
Destruction of my Florida scheme.	5000

Total, - \$6420

Now, the most of people would go nearly crazy over such a loss as this; but I have learned to take things cool, and to be happy under all circumstances. I have a good yield of honey, and will make all I can out of it. J. H. MARTIN.

Later.—My Florida friend of last season is here again. I have just had a pleasant visit with him. He started with 10 swarms, increased to 38, and obtained 300 lbs. of extracted honey; sold for 25 cents per lb. By transferring out of season he got his bees to robbing, got stung, and got everybody else stung around him. My Florida fever begins to afflict me just a little—somewhat intermittent.

Hartford, N. Y., Sept. 25, 1885.

J. H. M.

Right glad we are to hear the report, even if it is a failure, friend M. Now, had you consulted your A B C book you would have noticed that I emphatically insist that bees shall have ventilation through both top and bottom of the package, where they are to be sent long distances. I have experimented in this matter to my heart's content, and I thought I made it so plain in the A B C book that no one, after reading my directions for moving bees, would have made such a mistake. I can take a powerful colony in the hottest day in July, and by covering both top and bottom of the hive with wire cloth, so that the bees can send a stream of air right through, they can be shipped safely almost anywhere. The perspiration and hot air rise right through the upper wire cloth, providing a stream of cold air can come right in from the bottom. Long ago we also gave warning that the food, whether candy, honey, or whatever it may be, should by no means be on the bottom, for dead bees to fall into; besides, the bottom is all wanted for ventilation, as I just told you. I

do not think there is a better plan for fixing the candy in the cage than the one we illustrate and describe in the A B C book, and this cage has gone longer distances than from here to Florida, with perfect safety. There are, however, losses in shipping bees occasionally, which we have never yet been able to understand; but I should say that nine-tenths of your bees ought to have gone through in good order. Now, friend M., do not make out any more bills of \$6000 and over, for loss of "castles" built entirely in the air; but let you and your friend go to work next season testing a pound or two at a time, until you are all right. In fact, you ought to do that in any business. Send three pounds first; if they go all right, then try ten pounds; next twenty-five. If all these go safely, you are ready to try fifty or perhaps a hundred, if you choose.—To be sure, the orange-men in Florida, and sugarmen too, for that matter, ought to help us, and we ought to help them too. In the same way, we ought to help the express companies, and they ought to help us, and will, if we go about it in the right spirit. We are a band of brothers all round, and can surely work together. Don't you remember who it was that said, away back, years ago, "We be brethren"?

OBSERVATIONS UPON DRONES.

BY L. L. LANGSTROTH.

BEVAN says that the drone hatches on the 24th or 25th day after the egg is laid. I know of nothing more definite on this point.

To get more precisely the facts, on the 16th day of last July, a drone-comb was put, at 5 A. M. centrally in a strong colony, which had been fed for several days, as the drones were being expelled from many hives. At 9 A. M. the queen was found on that comb, having laid three eggs. She had just begun laying. At 9 A. M., on July 17, it was removed to a strong colony, without queen, eggs, or larvæ. On July 27, many cells were capped, and on July 23, at 2 P. M., some 200 were capped, many eggs having, for some cause, disappeared. On Aug. 9, none had hatched. On Aug. 10, examinations were made every hour. At 5:30 P. M. none had crawled out; at 6:30 two had hatched, and a third was hatching. If these drones came from the first eggs laid, they took about 25 days and 8½ hours to develop.

At 6 A. M., on Aug. 11, many more had hatched, and at 6 A. M., on Aug. 12, all but 17 had hatched. At 6:30 P. M. all but two had hatched, and at 6:30 A. M. of Aug. 13, the last one was found with the cap off, trying to crawl out; it was strong and perfect. Now, if the egg producing this drone was laid just before the comb was removed, then it took nearly 25 days to mature.

During the whole time of these observations, the weather was of the most favorable kind—the thermometer ranging nearly every day above 80° Fahr., and being only once as low as 62°. The colony was kept in good heart by daily feeding, and I can think of nothing which could have retarded in the least the development of these drones, unless possibly the fact that from so many of the eggs having disappeared they were not as compact in the comb as they otherwise would have been. In this observa-

tion, although there could not possibly have been more than 24 hours' difference between the laying of the first and the last egg, there was about two days and a half between the hatching of the first and the last drone.

It is quite interesting to watch the different actions of just hatched workers and drones. The worker, true to her name and office, begins to crawl over the combs as if to feel her legs, stops occasionally to clean herself up, and before long helps herself to honey from an open cell. The drone, on the contrary, is a born dependent. The first act is to touch the nearest worker he can reach with his flexible antennæ, and, begging to be fed, he is at once supplied with honey disgorged from the proboscis of his attentive nurse. And so he goes on all his life, seeming to prefer to be fed, although perfectly able, if needs be, to help himself.

A very bad name has always been given the drone. Virgil has his fling at him, stigmatizing him as having no proper office in the economy of the hive—seeking only to devour the stores which he had no share in collecting. I wonder what the poet thought he was made for! or as he says that the bees collected their young from the flowers, being too chaste to breed them, what motive he could have thought they had to gather in such useless consumers! And yet without any special pleading, how much can be said in his defense! It is only too evident that his proboscis is too short to suck honey from the flowers; that his legs have no pollen-baskets; and that he can secrete no wax. Great as his bulk is, he has no sting, and can do nothing for the defense of the commonwealth; but then, without him that commonwealth could have no existence. The sole object of his life seems to be, at the proper time, to fertilize the young queen—and this he is always ready to do. Now, why should we blame any creature which fulfills the special object of its creation? And yet I fear me, in spite of all that can so justly be said in his favor, our poor drone will always be cited as an incorrigibly idle reprobate, who meets with only his just deserts when, after a life of pleasure, he is killed without mercy by the industrious workers. He will always be known as Shakespeare's "lazy, yawning drone."

Oxford, O.

REV. L. L. LANGSTROTH.

CONVENTION NOTICES.

The Central Illinois Bee-Keepers' Association meets at Jacksonville, the last Wednesday and Thursday in October. CHAS. DADANT.

The Central Michigan Bee-Keepers' Association will meet in the Pioneers' Room, in the State Capitol, at Lansing, Mich., at 9 A. M., Nov. 12, 1885. Every one who has bees, or is interested in bee culture, is invited to attend. E. N. WOOD, Sec.

The Progressive Bee-keepers' Association of Western Illinois will meet in Macomb, Ill., on Thursday, Oct. 15, 1885. Let everybody come and have a good time. Good speakers are expected.

J. G. NORTON, Sec.

The Wabash County Bee-Keepers' Convention will meet in G. A. R. Hall, North Manchester, Ind., Oct. 10, 1885. All bee-keepers are earnestly requested to be present. J. J. MARTIN, Sec.

The Western Bee-Keepers' Association will hold its fourth annual meeting in Independence, Mo., Thursday and Friday, Oct. 15 and 16, 1885. The association will endeavor to make this the most interesting meeting yet held, and will spare no pains within its means to make it in every sense valuable to all. Several of our most prominent bee-keepers have signified their intention to be present.

C. M. CRANDALL.

REPORT FROM W. S. HART.

ANOTHER VERY FAIR REPORT, AT LEAST, FROM
FLORIDA.

EDITOR GLEANINGS:—According to custom I will now make a report of the season's work in my apiary, up to date. Last season closed with 117 colonies; started this season with the same, all in good condition; increased to 148, and have taken, as nearly as I can tell at present, 11,900 lbs. of honey, of which 250 was comb in pound sections, and the rest extracted. This, as you will see, gives me about 100 lbs. to the colony, spring count, which is about thirty pounds below any previous average made since I took charge of my bees, eight years ago; and although a small report, still I believe it is a "paying" one.

The season proved an anomaly. Almost every thing in the way of bloom has been from two to six weeks later than usual; and when it did come it was quickly over. Saw-palmetto produced almost no honey, and gallberry very little. The bright amber honey of May and the first half of June, that usually constitutes our first surplus for shipping, was entirely wanting this season. What early honey we did get is considerably darker, and has a stronger flavor than usual. Mangrove honey came in very late, and, like the cabbage-palmetto, which yielded freely, was in bloom but a short time. The mangrove, however, was blooming freely some days before the bees fairly went to work upon it. Why this was so is a mystery to me.

The mangrove and cabbage-palmetto honey is of as fine a quality as need be. I believe it is better than ever before, and partly, perhaps, on account of my new method of curing it in a sun-evaporator under glass instead of as formerly in large tanks, which were run out into the sunlight when full. I may speak more particularly of my new honey-house and fixtures at another time.

The honey crop for the State will, so far as I can learn, run short of an average one in about the same proportion as my own, or, say, one-half a crop; but that fact seems not to have discouraged any of our apiarists, so you may look out for a big crop from our State next year.

A larger proportion of comb honey is being raised than formerly; and surely, if it can be placed in the market without breakage, it will bring the "top price." Now for a few words on various subjects.

WAX-EXTRACTORS.

I have now had in use for the past two years the sun-extractor described by Mr. O. O. Poppleton in back numbers of GLEANINGS, and so far I have seen or read of no better plan for rendering wax. Its good points are, 1st, Its cost is very little; 2d, Almost any one can make one who has a frame of sash; 3d, It cleans the wax perfectly, and brings it out bright, clean, and handsome, the first time melting, and no mussing about it; 4th, By having two pans for it, one can always be at hand ready for all odd scraps, while the other is in the extractor.

Well, perhaps I had better not tell the rest now, but will just say, *try one*.

YELLOW JESSAMINE.

This grows plentifully throughout our hummock and scrub lands, and considerable of our winter honey comes from it. Both myself and many of my neighbors have eaten freely of it, both after it had been capped over and also before, when it had just been gathered, and I have never known any ill

effects, nor have I ever found that it injured my bees in any way; yet Dr. J. P. H. Brown tells me that in Georgia they lose a great many young bees by it. Evidently, locality makes a great difference, or else there is some other plant that causes the trouble. The honey is never taken from the hives to be shipped, as all of it is needed for brood-raising.

CLIPPING QUEENS' WINGS.

Let me say, that I vote for clipping the queen's wings *every time*. I have done it for years, and Mr. Mitchell, who has had full charge of my apiary for the past two years, does the same. It would take considerable money to hire us to give up the practice. It certainly has been of great profit to me, and I think the loss of one queen is all there is to be charged to the practice in all this time. Some of my neighbors who do not practice it are losing more or less swarms that go to the woods every year, while we have not lost a colony from any cause for about three years. I think this last fact may be a good argument also to support a number of statements and claims that I have made in past writings. It also speaks well for Harrie's management. No artificial swarming for us, if we are working for extracted honey.

I make it my business, and I consider it the business of every officer of any bee-keepers' society to watch over the newspapers of their respective States; and if any thing is published that is damaging to our industry in any way, at once reply to it; or, if it is false, correct it by an article showing its fallacy. Editors are sometimes misled, but seldom or never publish any thing of the kind with a deliberate intention of injuring any honest industry, and, I believe, are always glad to receive and publish such matter as is sent to them by any well-known and respected bee-keeper. Such a letter may be made not only to counteract the influence of the libelous article, but may give a few hints and facts that will help create a "hankering" for some of that genuine "bees' honey." Of course, I would have all bee-papers ready to refute any misstatements in the future as in the past; but bee-papers go mostly to bee men, who know honey when they examine it, while the newspapers carry the correction right where the other article went, and it thereby reaches the parties most likely to be influenced.

Hawks Park, Fla., Aug. 31, 1885. W. S. HART.

APIS DORSATA.

A FEW MORE BRIEF WORDS FROM FRIEND BUNKER.

FRRIEND ROOT:—In reply to questions in GLEANINGS of May 15th I will say, the comb for brood is not cylindrical, but flat. On the right of this comb, however, and attached to it—yes, forming a part of the brood-comb—is this cylindrical comb. Though built on the same limb as the brood-comb, yet the store-cells are so elongated in the middle portions of the comb as to give the general form of the comb a spherical shape. Perhaps this is the better term to use in describing the honey-comb of this bee.

I could discover no drones or drone-cells in the stock I captured. The brood-cells were all the same shape and size—at least so far as I could discover. The store-cells, however, varied much in depth, according to measurements given. No brood is ever raised in the store-cells. These are exclusively for honey, and so I have called them the honey-comb

in my description. The question of drones and queens must yet be answered. In the *Apis florea*, the queen and drones are much larger than the worker-bee, comparatively, than is the case in the *A. indica*. The drones are of a beautiful slate color. I am inclined to think that this bee has more than one queen to each stock, but am not at all certain. As I remarked in a former letter, the *Apis florea* resembles the *A. dorsata* in many ways.

A. BUNKER.

Toungoo, British Burmah, July 3, 1885.

Many thanks, friend Bunker, for the additional information you give us. It seems to be a little hard for us to get hold of the idea of these cylindrical honey-combs. Could you not make some kind of a drawing of it when you are writing?

In addition to the above facts, friend Bunker sends the following in a private letter; and this private letter is of so much interest to all who are interested in *Apis dorsata*, that I am sure friend Bunker will excuse us for making at least a part of it public. It is as follows:

You have very kindly offered to help bear the outlay in experimenting with *A. dorsata*. I should not hesitate to accept your kind offer, if I were sure I could get any good for you and the public out of the experiments; for the fact is, we missionaries, with our divided families, part here and part in America, find it hard to make the ends meet. We can not use our allowance for support to the best advantage. No complaint, however, you understand.

Doubtless if I had ample funds I could drive the experiments with *A. dorsata* much faster. I have to hire men to climb the trees and transport the bees 23 miles, and carpenters to make the hives, which is expensive. The last hive cost me 12 rupees (a rupee, or, rather, 25 rupees, equal \$1.00). I paid 8 rupees for men to climb for the bees and bring them into town. Of course, I now have the hive and I shall not be obliged to get another very soon.

By the way, every hive must be thoroughly protected from ants, by surrounding the base with water or oil. I am exceedingly interested in these bee experiments, and am leaving nothing undone by which to post myself on all the ways of bees, and I shall do my best to give *A. dorsata* a fair test.

In closing, my dear brother, allow me to bid you "God speed in your good work." You have been liberal to this missionary, for which you are held in grateful remembrance.

I hope to send to you soon an order for tin pails for honey. My helper in the study of bees, a very intelligent Karen, wants to try an experiment in marketing the 40 bbls. of honey from the *A. dorsata* of his village. He thinks that if the pails are ant proof he can put up the honey with a neat label, and ship to the Rangoon market, now the railroad is open, and make a good profit. I mention this as a fact of progress; so, look out for an order, say when the season slackens with you, as I suspect then will be best time to buy.

A. BUNKER.

Friend B., I believe the best way of expressing my hearty sympathy with your enterprise for putting the *Apis dorsata* honey up in tin pails for market would be to tell you that I have placed to your credit \$25.00, to be used for tin pails, or in any other way you may suggest. If, as you suggest, it should not amount to any thing, I will risk

so much in the experiment. I know how it is with missionaries, and I have always had reason to believe that they as a rule make pretty careful investments.

CLIPPED QUEENS.

FOR AND AGAINST.

IN reply to your questions on page 455, arising from comments on Mr. Doolittle's article on clipping queens, I will say, from my observation and experience, that it takes a natural swarm but a very few minutes to ascertain whether or not the queen is with them in the air, and every thing in order for further proceeding. If the queen be not clipped, swarms will issue quickly, and at once cluster; while with a clipped queen they are longer leaving the hive, and so much time is usually spent before clustering (which they often do, and sometimes do not), that many bees return to the old stand. Even if the queen be found and caged immediately, and hung upon something where a few show disposition to cluster, as Mr. Doolittle mentions, as a rule it does not warrant their clustering there. To suspend the cage among the bees in the air by means of a long stick, and "fly" it around with them often induces them to cluster quickly; but even this is not usually satisfactory. If they do not happen to fly all over your yard and your neighbor's yard too, as swarms with clipped queens often do, they do take up a good deal of time. This may not matter, if one has a few colonies; but when a dozen swarms are likely to come out within an hour, some quicker method of disposing of them works better for me. I have occasionally had half a dozen swarms issue, one after the other, with an average difference of not more than three minutes, with queens having good sound wings, and I alone find no difficulty in getting each swarm hived by itself with its own queen, as it should be. Imagine the "muss" I should have had, if those queens had been clipped. Some would say the bees would return to their respective hives. This they *might* do, but more than likely some one or two out of half a dozen would get the most of them. I believe more clipped queens are lost at swarming than are swarms by absconding. If they are not lost outright, they are quite often balled or superseded shortly after.

Now, doesn't it depend upon the comparative value of queens and bees, together with one's ability to manage successfully at all times, whether or not we can advise clipping? As for me, in my home apiary, managed expressly for comb honey, I allow a certain amount of swarming, and prefer the queens *not clipped*; while if I were running an apiary away from home, equally strong, for comb honey, and not in charge of an excellent hand, I would allow no natural swarming, and have all queens *clipped*.

C. W. KING.

Kibbies, Mich.

Friend K., I have had queens with clipped wings act just about as you describe, a good many times, and that is one reason why I have several times before made the statement that it seemed to us we had more bother where the queens were clipped than where they were unclipped. I agree with you, that it is quite likely circumstances may greatly alter cases in such matters.

SOMETHING ABOUT BEES AND BEEHIVES.

SOME INTERESTING FACTS AND REMINISCENCES
FROM ONE OF OUR VETERAN READERS.

ALTHOUGH not recognized among the more successful bee culturists of the country, save and except father Langstroth, I am, perhaps, the oldest. I have been caring for and handling bees for at least fifty-two years. Before I was out of my 'teens I had invented various "contraptions" for the more ready and careful handling of bees, none of which are now worthy of mention. I knew very little, however, of what others had been doing with and for the "little busy bee." I had read no books on the subject—knew of none—and had only my own and my father's experience as my guide. It is strange that it should be so; but it so happens in this world that one man's experience amounts to very little. Evolution (development) is indeed the order of creation. I knew what a drone was, and *his* uses. I knew what a queen was, and the part *she* played in the economy of the bee-hive. Then, however, she was commonly known as the "king-bee." But I now wonder that any one could have been so ignorant, and yet be a comparatively successful bee culturist. About this time a little A B C book on the honey-bee, fell into my hands, which was indeed a revelation to me. I arose from the perusal of this little volume, the title of which I have forgotten, delighted with what I had learned, but amazed that such knowledge should have been kept from me so long. This book confirmed all I had ever learned, and told me of wonders far beyond any thing I had ever imagined as true of the honey-bee. And it was just at this point that father Langstroth came upon the scene, and told us of the wonders he and others had discovered in this line. He came with book and hive, and said: "I am going to tell you of mysteries more wonderful than any tale ever told by Arabian Nights; I am going to tell you of the mysteries of the honey-bee." To say that I read his book with profit, is tame and flat; I read it with the greatest pleasure, delighted with the knowledge it afforded, and thankful that my eyes had been opened to the truth as it is. I at once adopted the Langstroth hive, and for more than twelve years I used no other. I followed it through all its different forms, and imitated it in all its different styles. However, after the war, having got rid of all my old bees and hives, by a change of location from the Valley of Virginia to tidewater near Richmond, I began to tinker with other styles and make of hives; and the consequence is, I have now in use about 17 different make of hives—just 16 more than I ought to have. I have the four different styles of the late M. Quinby. I have the Simplicity, the Gallup, the Triumph (in two different patterns) the American (in two different styles), the Maddox (in two different forms), and three other hives, the paternity of which is in obscurity. One of these has 10 combs 20×17 inches. One has 12 combs, 12×14 in., and one 10 combs, 11×13 inches. In addition, I have three kinds of my own get-up. So you will see I have had quite an experience with hives. Pope said the best government was the one best administered. I might say the same of bee-hives—the best one is the one that is best handled; and yet there is a difference, under the same treatment, worthy of consideration. Of course, I think

mine better than any other. I aimed to have it free from the objectionable features I had discovered in nearly all the others I have named. Without intending it, the inside measurements of my hive are nearly precisely those of the Langstroth hive. But I run my frames—13 in number—crosswise to the opening. There is no special advantage in this, except in the facility of handling them. I work entirely from the rear of the hive, and the bees in front scarcely know what is going on till the honey is all extracted.

I begin the honey season by placing all the brood-combs in front, and the hive is frequently overflowing with bees before any brood is found beyond the seventh comb, and the six rear combs will have in them nearly all the honey that is in the hive. This is a consideration in extracting, if in nothing else. I am not bragging on my hive. I have no special vanity that way, but only write to say what I do and why I do it. G. K. GILMER.

Marion Hill, Va., Sept. 9, 1885.

REFINING HONEY WITH ANIMAL CHARCOAL.

CAN IT BE DONE IN THE WAY WHITE SUGAR IS REFINED?

UPON seeing inquiries in GLEANINGS regarding the possibility of bleaching dark honey by filtering it through bone-black as syrups are bleached before crystallization takes place,

I would say that, as I am considerably conversant with the sugar business, will reply that, as the charcoal filters which are used in our refineries are so very expensive, it would be entirely impracticable for any one in a small way to ever refine his fall honey, even if it could be done. I think, from what I know of the manufacture of sugar from our northern sugar-cane juices, and of the nature of their juices as compared with honey, that it would be very doubtful if any such process would prove successful. In making sugar we treat the expressed juice, first to a lime bath, at a temperature a little less than the boiling heat, about 18.5° Fahr.; then when it is reduced to a semi-syrup it is run in on the top of the bone coal, which consists of burnt animal bone, which is ground nearly as fine as coarse blasting powder. These filters are about 12 in number, generally, and are some 3 ft. in diameter by 12 or 18 ft. high, made of boiler iron riveted together as engine boilers are, in the same way. This saccharine liquid slowly leaches through the filters, after which it is pumped up into the vacuum pan, where it is reduced to the proper density for granulation, and it is then discharged. If honey were to be put through the charcoal filter it would first have to be reduced in density to about the consistency which it comes in from the field, and then be evaporated afterward, so as to give it to again its proper density.

While going through the charcoal, it loses much of its coloring matter; and while there it casts off some of its characteristic flavor. It also takes on a borrowed flavor from the bone black, which, to many, is not pleasant. Now, were honey to be subjected to even the leaching process, I think it would afterward hardly be recognized as *honey* again.

The crude sugars of commerce are not bleached in this way. The sugars resulting from this process make a common brown sugar. The brown, or

crude sugars, are put in molds, and clay is placed on the top of each mold, and water is filtered down through the clay and the sugar, which bleaches it white.

Our bees are jubilant over the enormous white-clover honey harvest which they are garnering up rapidly. They built up surprisingly on the fruit-bloom. C. F. MILLER.

Dundas, Minn.

Thanks, friend M. It had already occurred to me that the honey would have to be reduced with water before it could go through this filter of animal charcoal. Then, of course, we should be obliged to thicken it again by boiling or evaporating; and unless we have expensive apparatus for the purpose, I am afraid we should injure the color and flavor of the honey more than it would be benefited. At present it does not seem as if the plan were very practicable.

CAGING QUEEN-CELLS.

SOME DIFFICULTIES ATTENDING IT.

WE are having a rather poor honey season. We got no honey from clover, to speak of. There was plenty of bloom, but too much rain; and now we are in a great basswood flow, but poor weather for the little fellows to work. One day it was so cold they hardly left the hive, although the day before they had just been rolling in honey; then we have so much high wind here in the prairie, and now it has been raining the most of the time for three days and nights. I have increased from 6 to 18; have sold several queens, and the most of my hives are very strong and active, but they don't take possession of the supers very readily. I put starters in all but part of one frame. I put in small pieces of comb, and those they went right into the same day.

I lost nearly all of the first lot of queens that I had hatch out. I was working away from home, and could see them only nights and mornings, so you know what happened. The first that hatched destroyed the rest, so I fixed some little cages and put the cells in them, and hung a frame full of these in a hive. I have had good success in this way. One cell got badly dented; and when it hatched the queen had frizzled "bangs," or her wings were frizzled or curled up so she could not fly. We tried to straighten them, but could not, and to-day I find another with one wing curled up. What can be the cause? and will they ever get so as to fly?

I saw an article in a book called "100,000 Facts," by one Shafer, in regard to fertilizing queens in confinement, telling just how to do it. I have fixed a cage, and am going to try it. Now, is this a fact or a fancy? If it has been done as long as he says, why haven't we known it before?

Sac City, Iowa, July 22, 1885. JOHN BARLOW.

Friend B., one great reason why we gave up caging queen-cells is, that so many of the queens would be hatched with imperfect legs or wings, especially when we began to have cool nights. The animal heat of a colony of bees is not sufficient for the purpose, only in July and perhaps the month of August. Even then we occasionally have cool nights that produce such results as you mention.—Fertilizing queens in confinement is an ex-

ploded myth, as you will see by the A B C book. It is true, however, that every once in about so often somebody comes up and thinks he has made it a success; but it is usually soon dropped again. I would not advise anybody to waste time with it.

INTRODUCING VIRGIN QUEENS.

SOME VALUABLE FACTS GLEANED FROM EXPERIENCE.

I MAKE a common practice of letting virgin queens run in at the entrance, as soon as possible after a colony has sent out a first swarm. As a large part of the bees left in the old hive are young bees, the queen is hardly noticed, and, true to her instinct, she destroys the queen-cells, preventing all after-swarming. I also remove laying queens and introduce virgin queens at once, with good success, never having lost more than a small per cent of those introduced in this way. My experience has been, that the action of the queen has a good deal to do with safe introduction. If they are strong, and able to stand up for their rights, they are less liable to be killed than weak ones that are just able to crawl.

WINTERING.

We have experimented pretty thoroughly, and have had the best success packed in chaff on summer stands, with good well-ripened honey for stores. Pollen they will not eat, if they have plenty of other stores. When they get out of other stores they will eat pollen rather than starve.

THE FOUNTAIN PUMP.

With one of these we control the clustering of swarms. If they commence clustering on high trees, out of reach, by directing a stream of water on the limb they will leave it and cluster on a lower limb.

ALSIKE CLOVER.

I believe this to be one of the best paying plants for artificial pasturage. We have about 20 acres, and with us it has never failed to yield a fair amount of honey. This season white clover was almost an entire failure, and nearly all of our white honey was from alsike. It is equal in every respect to the best white-clover honey. Aside from the honey obtained from it, it pays well to raise as a hay crop.

BUCKWHEAT.

Buckwheat also pays well in this locality. It seldom fails to give something, and some seasons we get immense yields of honey from it. The best variety which has come under my notice is the "little silverhull." This is far ahead of the old "silverhull," both for honey and grain.

SUMAC.

We have had our first experience with this, this season. It lasted about a week. The strongest colonies stored whole crates (42 lbs.) from this source alone. The honey is darker than clover, but when well ripened it is nearly as good, and is selling at the same price in our markets.

6—O. G. RUSSELL, 24—38.

Afton, N. Y., Sept. 7, 1885.

Friend R., I should agree with you in almost all you say; but this is the first time I ever heard of more than one kind of silverhull buckwheat. Where did the seed come from, and has it been advertised under the name you give it? Alsike clover, I believe,

is one of the few honey-plants that it is safe to go into, and I should think that 20 acres might go a good way toward giving a profitable crop of honey, with the number of colonies you have. When we get that book on buckwheat, and the other on raspberries, we shall want a book on alsike clover.

AN IMPROVEMENT IN HAND FORCE-PUMPS.

THE JOHNSTON PUMP.

THE Smith pump that we have been selling for several years past gives wonderful results, and costs only a small amount of money; but I have always found it hard work to use it, because the power must all be applied directly to the piston-rod, which in my hands wiggles about in an unpleasant way when I am trying to throw water a great distance. It also throws water only while you are forcing the piston down. While in New Orleans, in looking over the "wilderness" of pumps I came across the little pump shown below, and, as a matter of course, I took hold of the handle to see how it worked compared with our own Smith pump.

THE NEW JOHNSTON PUMP.

You will notice that it has a handle like ordinary cistern-pumps; and while this handle guides the plunger, it also gives us a lever purchase, which always seems to me to be quite an advantage. Still further, it throws a continuous jet, or stream, and this stream can be guided in any direction you wish, by simply turning the rubber hose. I was delighted with it, and so was Ernest. I think the agent sold these pumps at \$2.00 or \$2.50. I told him that I had a large trade in our dollar pump, and that if I purchased I must get them so I could sell them for an even dollar. He thought the price was wonderfully

small for his pump; but when I told him that I would give him so much money for a very large number of pumps, he finally accepted my offer, providing I would introduce them far and wide. The drawing explains the whole matter, although I might, perhaps, add that there is an air-chamber in the shape of an extra barrel surrounding the tube that carries the jet (the one to which the handle is attached), and this air-chamber makes the jet continuous. The stream it throws is small, but you can easily make it larger by reaming out the orifice with an awl or pointed instrument. The pump is nicely gotten up, and works like a charm. The prices, both wholesale and retail, will be the same as mentioned in our price list; namely, 2 for \$1.75; 3 for \$2.25; or a case of 10 for \$15.00. If wanted by mail, the postage will be 60 cts. each.

MRS. HARRISON TALKS TO US ABOUT CONVENTIONS.

AND ESPECIALLY OF THE CONVENTION OVER THE WATER, WHERE FRANK BENTON RESIDES.

I WAS laid aside lately for repairs, and while indisposed there was nothing that I enjoyed more than looking at the "migratory shadows" of the members of the New Orleans and Syrian conventions. While looking at the former, it brought many pleasant recollections to mind, as I scanned familiar faces which had gathered there from the different sections of the continent. It was a joyous time, and one long to be remembered.

The "shadows" of the Syrian convention are all strange, yet peculiarly interesting, from the fact that eight different languages are represented by the eleven composing the group. The peasant's daughter, according to the custom of the country, allows us to see but a small part of her face, and as we gaze upon her we fervently hope that her labors for bee-keepers may be remunerative, and be the means of elevating her mentally and socially.

I pity the poor bees that have to live in jugs and cylinders. I don't believe the bees of our country would stay in them; they would desert, and I'm thankful that Mr. Benton is introducing a comfortable hive into their country. The frame may be all right, but it has a wonderfully long name. I've guessed, and I've guessed, and guessed again, how it is held in place, put on my specs, and peered down into the hive to discover something, but failed. Mr. Root, don't you think the ends of the hive have tin or zinc, like this **52525252**? And the hive is reversed by turning it over, is it not?

Peoria, Ill.

MRS. L. HARRISON.

I am as much at a loss as yourself, my good friend, in determining how friend Benton holds those frames, all alike all around, just like a slate-frame. At the Ohio State Fair our old friend Benedict had some hives with similar frames, and they were held by bent wires like those you mention. But the strangest part of it all was, that although friend B. has hives, 20 or 40 of them, in use, in which the frames could be used just as well one side up as the other, he never reverses them at all. He says he does not believe in it. Aren't we human beings "funny," any way?

THE RASPBERRY.

ITS SOIL, AND HOW TO PROPAGATE.

THE raspberry is divided into two distinct classes—the "Black cap" family that is propagated by the tips of the young canes taking root in the soil during the autumn months, and the "Red" raspberries, which are propagated from root-cuttings, or by the suckers, which are produced freely from the roots. The former is of American and the latter of foreign origin, and both, as a rule, produce fruit only on canes of the previous year's growth—the canes which have borne fruit, dying during the latter part of the summer, and during autumn, and the young shoots which started out vigorously from near the surface of the ground, early in the season, taking their place to bear fruit the next year.

The raspberry follows the strawberry in the time of ripening; and while it is one of the most wholesome, refreshing, and agreeable mid-summer desert fruits, it is also largely used in canning and in making syrups, jellies, and jams. The black-caps are easily dried, about three quarts of the berries making a pound of dried fruit, and the market quotations of 25 to 35 cts. per lb. seem to indicate that dried raspberries are appreciated.

That a fruit so highly esteemed by nearly every one should have been so much neglected, can be explained only on the hypothesis that there is a widespread misapprehension in regard to the soil, culture, and pruning required, or that the productiveness, freedom from insects and diseases, and general reliableness of the hardier varieties of the raspberry, have been overlooked or underrated.

In the last five years our Kittatinny blackberry-canines have been killed to the ground twice by the cold winter; and apples, peaches, cherries, plums, grapes, currants, and gooseberries, have all failed once, and most of them several times, from the cold of winter or frosts of spring; but we have gathered five good crops of raspberries in that time. Then the growing of the fruits commonly found in our orchards and gardens means a continual conflict with rabbits, mice, caterpillars, borers, curculios, and currant-worms; but the raspberry bids defiance to all these. With us (and I might say in this section of country) the raspberry is entirely exempt from disease and the attack of insects.

RED RASPBERRIES AND THEIR PROPAGATION.

These, if let alone, will propagate themselves quite freely by sending up young shoots for several feet in every direction. When plants are wanted it is only necessary to let these suckers remain until the proper season for transplanting.

BLACK-CAPS.

These will propagate themselves to a limited extent; but the only certain way to obtain any considerable number of plants is to bend down and bury three or four inches of the points of the canes in the ground. We do this by inserting a mason's trowel four or five inches in the ground, at an angle of about 45 degrees; then, without withdrawing the trowel, the handle is raised a little, and the point of the cane pushed in under the trowel, and held there while the trowel is removed, and the soil firmed over the point of the cane by pressing on it with one foot. This work should be done about the first of September, and the tips of the canes will be well rooted, and ready to transplant, by the latter part of October.

TRANSPLANTING.

It is claimed that plants set in the fall will make a much stronger growth the first year, while the objections urged against fall planting are, that the plants are liable to be heaved out like clover and wheat by the alternate freezing and thawing in winter, and that heavy soils sometimes bake over the plants so as to interfere with the growth. An extra three or four inches of soil drawn up over the plants in the fall, to be raked off in the spring, or a small forkful of coarse manure dropped on each plant in the fall, is recommended by some of those who favor fall planting. Spring planting, as a rule, should be done as soon as the ground is in good condition for working; but when the plants are obtained within a short distance it is possible to make late planting successful. In May, 1883, we put out about 2500 plants when the young shoots were from four to eight inches high. The plants were conveyed, about 75 at a time, some 20 rods in a hand-cart, and I distributed them along the rows, taking care not to break the young shoots, and transferring along with the plants all the clay that adhered to the roots. In setting the plants, one person went along and put the plants in place, spreading out the roots and drawing a little fine soil over them; a second followed, pouring about a pint of water over the roots of each plant; and a third person, with a hoe, finished the operation by drawing an inch or two of dry soil over that which had been wetted. This transplanting was done in a very dry time, but there were not as many as a dozen plants which failed to grow, and they did well enough to yield about twenty bushels of fine berries in 1884.

The old stereotyped phrase, "Plant shallow," has become obsolete within a few years; and at present, most if not all of the successful raspberry-growers advise and practice planting to a depth of three or four inches. By planting at this depth they are less apt to be blown over by the wind, and my experience seems to indicate that they are more apt to live and grow, than when planted shallow.

R. M. REYNOLDS.

East Springfield, O., Sept. 8, 1885.

Thanks, friend R. for your suggestions. It seems to me the outlook is quite favorable for bee-keepers to have a good plantation of raspberries in connection with the honey business. The demand for the fruit is excellent; and with recent improvements in the way of evaporating and drying, there is little probability of any market ever being overstocked.

MORE ABOUT GELSEMIUM HONEY.

SOME ADDITIONAL FACTS.

WITH your permission I should like to make a few remarks in reference to the yellow jessamine, or *Gelsemium sempervirens*, of the South, poison honey, etc. I have lived in the South, and gathered this plant a great many times in its various stages of growth, and at all times of the year—have used the fresh infusion and tincture from the green root, and the infusion and tincture from the dry root, in many forms of disease, and in no case were there any injurious effects from its use, but the most desirable and agreeable results. I have chewed the flowers, and known others to do so, when I have been gathering the vine—have made the infusion from the

flowers, and used it myself, given to my family, and given to others many times in various forms of disease, and found it far less active as a remedial agent than the root, and not the least indication of poisoning in any instance. I think I am capable of speaking understandingly in this matter, as I have made extensive use of the remedy for *thirty years*, and have pushed the use of it to secure its constitutional effects *hundreds* of times, with the best possible results, but always careful to stop the use of the drug as soon as its relaxing effects were secured.

Two instances now recur to me, where it was used with intent to take life—one at the east, in one of the New-England States, the other in Michigan. Both were men, and convicts in State prison. Each man took one ounce of the fluid extract at one dose. Both were thought dead for a short time, but recovered fully without any bad results.

Another case is reported in the American Dispensatory, where a lad took six drachms of the tincture at one dose without any injury.

But there are *two* kinds of gelsemium in the South, and varying so little that I don't think one person in a hundred where I live knew the difference. In botany it is known as the *Gelsemium alba*, or white gelsemium, and is poisonous. The flowers are almost exactly alike in size and shape, bloom at the same time, but a lighter color, some almost white. The vine is larger near the ground, having tendrils like the grape or ivy, a darker color, tapering, and generally not so long; has a larger leaf, and opposite, on long footstalks. The root is light yellow, or almost white, and straight, and about the same length as the medicinal root, a sensibly bitter, disagreeable, sickening taste. The medicinal vine has no tendrils; the root is not sickening nor unpleasant to the taste of most persons. I have carried it in my pocket, and eaten of it daily, and known others to do so, as they ate "calamus" or ginseng, the latter commonly called "sang" in the South. The flowers of the medicinal vine are of a rich beautiful yellow, and impart a very agreeable perfume to the surrounding atmosphere, as fully as a field of buckwheat in full bloom, and freighted to its utmost with its precious burden of nectar.

The flowers of the other variety furnish no perceptible odor or perfume, unless in close contact, and will sicken and vomit severely by chewing or infusion.

The case of the lady from the North, as mentioned by A. T. P., explains as clearly as any thing can that she gathered the flowers of *Gelsemium alba*, and not those of *Gelsemium sempervirens*. A further explanation is also given by the fact that the person who furnished the honey for Mrs. Dukes "lived on the border of a swamp," the chosen habitat of the poison variety, "and that very few flowers of other plants were accessible to the bees," A. T. P. further says, "During the war many of the Federal soldiers who ate freely of the honey found out its deadly effects to their cost, although no deaths followed," etc. Observe, *they ate freely, experienced its deadly effects, but nobody died.* He goes on to say, "The poisonous qualities of wild honey are known to everybody—no one dare eat it." But the Federal soldiers ate of it *freely*. They must have been a tough set of men, that the Confederate guns and deadly poisons only made sick.

Now, there is nothing strange or marvelous in this account at all—just what would happen nine times out of ten, the world over. I know a case

where some honey was brought into a camp of soldiers in Michigan. They ate *freely* of the honey, and in a short time a hundred or more were terribly sick, and I think many of them would have died without immediate help. Many others ate of the *same* honey, and were not sick at all. Why this difference in effects? Two reasons will answer the question. 1. A constitutional difference, and state of the stomach.

2. They ate less *freely*—moderately, temperately. Suppose my horse has not had any grain for three or six months, and I should feed him a full mess, say six or eight quarts of grain feed for the *first* feed. What do you think would become of my horse? I think about the first work I should be called upon to perform would be to haul him away to his grave!

It is a very difficult matter to make people understand the difference between *little* and *much* when eating something they very much like. They seem to comprehend the matter only when the grip of pain is upon them. When I was living on the "Table Lands" of Tennessee, about twenty-five miles from Chattanooga, I was called in great haste to see a family that were taken suddenly and severely sick. Arriving at the house I learned they had cut a bee-tree and brought away a nice lot of honey, and all that were sick had eaten some of the honey. I wished to know how much any one of them had eaten, and, picking up a piece of nice comb, he replied, "A snack about this big, I reckon." Now, a "snack" of the size shown me would weigh $\frac{3}{4}$ of a pound; and with blood in their eye they declared the honey was poisoned, and would throw it away. I proposed, innocently as possible, to take the honey and test it for poison. Very cheerfully they gave me the honey, and I tested it three times a day—as long as it lasted!

A lady lives close by me now whom I think one teaspoonful of honey would kill in an hour. A brother of mine dare not eat *one drop* unless it has been boiled. A son of mine several years ago ate quite freely, when I was extracting, the first of the season, and was made terribly sick. The honey was white clover. Now, in every single instance that has come under my notice of honey-poisoning, it was the large quantity used that caused the trouble. Neither the honey nor the bees were to blame.

When water, cold or hot, will not extract half of the medical properties of the gelsemium in hours of digestion, I can't believe that the nectar, secreted in a single night, and gathered by the bees, can be so destructive to life.

In all I have said in regard to the poison variety, I do not mean to be understood that the bees gathered poisoned honey from the flowers because the plant was poisonous when tested medicinally. This variety will soon sicken intensely, taken in a warm tea or cold. The medicinal will not sicken. It does not *possess* nausea at all. The other day I was talking with a neighbor of Hiram Roop, who told me that Roop stated that the greater part of honey taken from wild bees is stung by the bees, and full of bee-stings, in that State, and is very poisonous. Since that I was talking with another old bee-keeper about poison honey, and I mentioned the account given by H. Roop. He made the same remark, and stated further that he had seen thousands of their stings in a piece of honey no larger than his hand, and that it was very dangerous to eat the honey.

I never had a thought that bees possess so much of the spirit of man that they would destroy their stores, or, what is the next thing to it, make it dangerous or destructive by their stinging the honey.

Elsie, Mich.

N. L. HIGBIE, M. D.

Thank you, Dr. H., for the points you bring out. I have for years been well aware of this fact: That it is not safe to eat heartily of any article of food when it first comes in season; but after having eaten of it for several days, increasing the quantity gradually, I find I can eat a full meal of almost any thing, without any disagreeable results. Nature seems to prefer taking small doses to begin with until she learns how to manage or handle a new article of diet. When she gets accustomed to it, then she disposes of a full meal, or even an overdose, without any "trouble in the camp." It seems to me hardly probable, however, that the deaths to which our attention has been called were produced in this way; still, it may be so. I know that it is quite customary, when a beetrue is cut, for those present to eat honey in excess—sometimes a full pound or more; and if those who do so have not tasted of any honey before for a year, I shouldn't be at all surprised if they were taken sick—yes, severely sick. It is, I believe, well known that people accustom themselves to poison, so as to take doses with impunity that would kill one, not so accustomed, outright. It is in this way that we become hardened, or inured to the effect of bee-stings. In cutting bee-trees, more or less bees are mashed. Sometimes great numbers of them are crushed all through the honey. It would not be at all surprising, if the poison set free from the poison-bags of these crushed bees would produce serious effects where said honey is eaten in large quantities.

A COLONY THAT KILLS ALL THEIR QUEENS.

WHY IS THERE NO HONEY IN THE CLOVER OR BUCKWHEAT?

I WANT you to tell me what ails my weak swarm. I found the queen on the ground one evening, and put her in the wrong hive, and lost her. There was no young brood, and I gave them brood from another. They raised two queens, but I found them both killed this morning, and still no queen or young brood. What had I better do with them? Can you tell me why the white clover and buckwheat have no honey in this year? I have just come from the buckwheat patch. It is in full bloom, and no bees in the patch. The main honey flow was from the basswood. R. H. WHITCHER.

Patton, Ind., Aug. 25, 1885.

Friend W., I can not say why the colony you mention kills all their queens; but in answer to your question what to do with them, you must get a laying queen in the hive by some means. As they have been queenless already for some little time, about the only way to save them would be to give them a fertile queen at once. They probably have some sort of a queen, or something that they consider to be a queen, and she must be hunted out and removed before you can do any thing.—I can not tell why there is no honey in the clover or buckwheat this

season; but I can tell you that it is something that happens once in a while—oftener with buckwheat than with clover. The honey secretion may commence, however, at any time; and if you keep watch I think you will see your bees on the buckwheat sooner or later.

A GLIMPSE AT THE HOME OF ONE OF OUR MICHIGAN FRIENDS.

HIS SHOP AND APIARY, WHERE HE WORKS.

SEND you by this mail a photograph of my chaff-hive apiary of 83 colonies. The little white dots in the yard are white clover. Then comes our strawberry-bed and other garden truck. It being the height of the swarming season, my partner (see Mar. 15 GLEANINGS) is out with the Shepard living-box, and I with my basket, with a piece of comb securely fastened in the bottom, and a handle attached to the outside of bottom, which I much prefer to the box. Mrs. H. stands on the walk leading to the honey-house, with smoker in hand, all loaded, in case it is needed. The shop and lumber are in the background. The grapevines and other foliage show more densely in the picture than they really are. The hives are in rows both ways, and alternate red, white, and blue each way in the rows. Our house stands just to the right, where the walks diverge.

With this short explanation you will comprehend the situation. GEO. E. HILTON.

Fremont, Mich., Aug. 17, 1885.

Glad to see you, friend H., and to take a look at your bee-hives and other improvements round about. Your letter is altogether too short. I presume that house with a flag floating on it is the honey-house, but you don't say so. The queer-looking arrangement in your hand, resembling a peach-basket fastened to a pole, is, I presume, for the purpose of taking down swarms. No doubt this will answer an excellent purpose, but they are so easily mashed up is one reason we have not adopted them more. We suppose your "partner" is that little eight-year-old chap from whom we had a letter on page 207, GLEANINGS for March 15. The building right back of the honey-house, striped with white battens, is probably the shop where "Uncle George & Co." hang out their shingle; and that is where the 100 chaff hives were made for that man who lives in Ohio and sent away off to Michigan.

Away back beyond the buildings we get glimpses of the pine-trees, and we presume the secret of your being able to make good work cheaper than we do is partly on account of those same pine-trees. You are right close to the pine regions of Michigan.

Our engraver did not make the white clover very natural, but perhaps he did the best he could at it. We should have been glad to get a glimpse of the strawberries, but they would be pretty hard to show in a picture.

Well, good-by, Uncle George & Co.; and we hope you may have lots of business and much prosperity; and, more than all, that your little partner, and his uncle too, may both be led in wisdom's ways.

APIARY AND WORKSHOP OF GEORGE E. HILTON, FLEMONT, MICHIGAN.

SWEET CLOVER.

HOW MUCH HONEY WILL AN ACRE OF SWEET CLOVER YIELD?

I WISH to say a word in favor of sweet clover, to the many bee-keepers who read GLEANINGS. Many years ago, long before I kept bees, I read in the *American Agriculturist* of sweet clover as an incomparable honey-plant. We read in A. I. Root's catalogue: "The statement has been made, that an acre will support 20 colonies of bees, and afford from 500 to 1030 lbs. of honey." The statement is not too high, as I will show.

Four years ago I bought of A. I. Root 4 lbs. of sweet-clover seed. I sowed the same in April, with oats, on one acre of land, and got a very thin stand. I think the oats smothered it out. The next year it blossomed and seeded, but there was not enough of it for me to determine its merits as a honey-plant. Last year there was a thick mat of green growth, but no bloom. This year nearly the whole patch was covered with a dense growth of clover, which commenced to blossom about the first of July. Basswood opened about the 5th of July, and bees left every thing else for that. Immediately after basswood they went on to the sweet clover, and for about three weeks there was a continual roar of bees from "early morn till dewy eve."

I had, at the close of basswood, 35 colonies; increased during sweet clover to 46. At close of basswood I took off all sealed boxes of honey; at close of sweet clover I had over 500 lb. boxes of sealed honey, all from sweet clover, as every one in Western Iowa knows there is no bloom after basswood until blackheart, that yields honey. During this honey dearth the queens almost quit laying. Now, sweet clover fills up this gap; besides the surplus honey gathered, the hives are kept full of bees and brood, in the best of plight for fall bloom.

I should say, that the 35 to 45 colonies would use, in raising brood and filling up brood-frames, not less than 500 lbs. during the three or four weeks, making 1000 lbs. of honey from the one acre. The bloom can be prolonged until frost, by clipping off the tops, say 18 to 20 inches, when first seeds begin to brown.

To my Western friends, I think I can not urge upon them too strongly the importance of filling up the gap between basswood and blackheart, and sweet clover does it. To have the bloom every year you must have two fields, one following the year after the first, as it blooms only alternate years. I think one acre sufficient for 20 colonies.

Hillsdale, Iowa.

E. W. FITZGER.

Friend P. I am very much obliged to you for your report of sweet clover; but 1000 lbs. from one acre during four weeks seems to me almost incredible. If you will see what I say about the amount of honey that a single plant will yield, under the head of "Spider Plant," in the A B C book, you will see what an enormous quantity each plant must produce. Each blossom of the sweet clover would have to literally drip with honey, to give 1000 lbs. to the acre. Now, the spider and Simpson plant do drip with honey, but they don't furnish any such amount; and from careful examination of sweet-clover blossoms in localities where no bees have access, I can not feel satisfied that the amount of honey secreted in the blossoms is

very large. I am forced to the conclusion that your bees must have secured this quantity of honey from some other source. I may, however, be mistaken. I should be very glad indeed to believe it were possible for sweet clover to do what you claim.

FALSE STATEMENTS IN REGARD TO THE HONEY BUSINESS OF OUR COUNTRY.

As a protection to our bee-keeping population, we propose in this department to publish the names of newspapers that persist in publishing false statements in regard to the purity of honey which we as beekeepers put on the market.

MANUFACTURED HONEY.

WE are pleased to give place to the following excellent leading editorial by the *British Bee-Journal* of Sept. 1:

"The first work that came to our hands when we entered upon our vocation as a bee-keeper was that of Langstroth on the *Hive and the Honey-Bee*; and though these 'solid days' have long passed away, we have never forgotten the wondrous fascination of his charming style and the practical information we derived from the perusal of his work; and deep and sincere has been the gratitude we have ever since felt toward this 'old man eloquent' for all the pleasure and the instruction we received from his teachings. There was, however, one passage in his book which we would fain have wished had been omitted, and that was his recipe for making a beautiful liquid honey, which the best judges have pronounced one of the most luscious articles they have ever tasted. 'Making honey.' What an incongruity of language! Honey is the symbol of all that is natural, pure, and genuine; honey has been the theme of poets from the time of blind *Maenoides* to the present day; honey is the joy of age and youth; honey is the sweet, rich, bright 'effluence of the essence' of flowers, the most delightful and delighting of all the productions of nature; and we can never see the words 'artificial' or 'manufactured' conjoined with it without uttering an internal protest.

"We are, however, too apt to think that adulteration is confined to American honey; but the denunciations of honey mingled with glucose, etc., have been uttered as earnestly and as frequently by American as by British bee-keepers. In Cowan's *Guide-book* are to be found extracts from American journals, stating the extent to which adulteration is practiced in that country, and vigorously denouncing the practice. It is not only in New York or Chicago that this so-called honey is manufactured. In Switzerland this 'manufacture' is carried on to a large extent; the analysis of Mr. Otto Hehner informs us that the 'Finest Swiss Honey,' and the 'Finest Swiss Table Honey,' are 'to a certainty adulterated'; and yet this honey is to be found on the tables of all Swiss hotels, and is said to be much relished and patronized by English travelers.

"But, why need we look abroad? In our own country the manufacture of honey is carried on largely. Our attention has recently been directed to a wholesale price current of a city firm in which '—s Manufactured Honey' is advertised; and by it we are informed that 'the success of this article seems assured, and that the orders have come in so rapidly that the manufacturers have been unable to cope with the demand.' We have not handled or seen or tasted this 'article,' and therefore are unconscious of its virtues. It may be a most luscious produce, and suitable to the British palate; but, why call it 'honey'? Is not our language rich enough in itself to give it some other name, or would it not have been possible to derive from the Latin or the Greek some other appellation than that of our much-loved and time-honored term 'honey'? Honey is associated with our earliest (we had almost written 'our holiest') ideas of all that is sweet, pure, and perfect. The royal Psalmist can find no loftier comparison of his love to the 'words' of God than to honey,—'honey and (do we not almost hear the smacking of the royal lips?) the honey-comb.' 'How sweet are thy words unto my taste! yea, sweeter than honey to my mouth.' The Wise Man shows his appreciation of the virtues of honey by the wholesome advice he gives: 'My son,

eat thou honey, because it is good; and the honey-comb which is sweet to thy taste." The Easterns, when they wish to describe the advantages and fertility of a country, speak of it as "a land flowing with milk and honey." And therefore it is that we have so decided an objection that this grand superlative word should be degraded to that of a humble positive by its association with such adjectives as "artificial" or "manufactured." Are bees to be surprised in future by the devices of ever-modelling Man? Are we to pronounce that their "occupation is gone"? Is honey to be placed before the light of this new production? Not yet, we opine. Never was there a time when the culture of bees was more attended to; and never was there a time when men's minds were so exercised as to discover fresh outlets and new utilities for honey in the shape of confections, drinks, medicines, etc. We believe that yet there is a great future in store for the products of the honey-bee; and we trust that pure unadulterated honey will ever hold its position, and that our friends of the British Honey and Fruit-farming Companies will put forth every effort to penetrate to every hearth and home, and to establish the virtues of pure honey, and to prove to a discerning public the superiority of British honey, not only to the "manufactured article," but also to that which is so largely imported from foreign countries."

We wish especially to call attention to one point in the above excellent paper: and that is, the absurdity of labeling a manufactured article *honey*. Call it table syrup, nectar, golden drip, or what you choose, but don't call it honey. If it is good and wholesome, and people are satisfied with it, let them have it; but for pity's sake don't tell a falsehood on the label. The writer of the above justly declares that honey has been, and ought to be now, an emblem "of all that is sweet, pure, and perfect." And now why not let it be so still? I presume our good old friend Langstroth never dreamed of making a bad precedent when he spoke about a "recipe for making a beautiful liquid honey." Certainly he never thought of encouraging the idea of labeling goods falsely. If anybody wants corn syrup flavored to order, let him have it; but by all means have the label plain and honest.

I inclose a slip cut from *Hibou News*, Brim Mawr, Pa., on honey adulteration. N. J. ISRAEL.
Bealsville, O.

ROGUS HONEY.

The *Maine Farmer* is opposed to fraudulent practices, whether by the farmer or the living creatures under his care. In regard to the practice of making honey out of sugar by the simple process of putting it through the honey-comb, it says:

If the bee can get a living on his front doorstep he will go no further for it, even though acres of white clover are near. If sugar and water, or any suchlarine matter, be placed in the hive, or near it, the bees will store it in comb as long as it is provided. They handle it as carefully, and pack it away as neatly, as though it were honey; and when it is sealed, and offered for sale in handsome white boxes, it is apparently pure honey. Is it not a shame that the bee should be employed to carry on such abominable swindling? The bee-keeper who uses this method says: "Most persons can not tell by the taste whether it be honey or not." This may be true, because honey is not on the table often enough to make itself known. Experts, even, have failed sometimes to detect a counterfeit piece of money, but this did not help the counterfeiter, who went to jail as soon as found guilty.

Some bee-keepers report a yield of two and three hundred pounds of surplus comb from a single colony in one season, and they tell how 'twas done; and more and more, they advise others to adopt their method; namely, feeding sugar and water at a cost of not more than five cents a pound, and selling it as pure honey for twenty-five and thirty cents a pound. This practice does more to injure and bring into disrepute the honey trade than any thing else

said about it or carried on in it. It is rank dishonesty and cheating—that, and nothing less. Bees must be fed sometimes in the fall, to help them through the winter, and spring feeding is practiced to stimulate brood-raising, that the hives may be full of workers when the honey harvest begins; but every honest bee-keeper should use his influence against the comb-honey imposture—against the turning awry of the original purpose and design of the bee.

Very good, friends of the *Maine Farmer*. But I want to take exceptions to just one little statement you make—"some bee-keepers," etc. Now, I am pretty well conversant with all the bee-journals published in the United States, and I am acquainted with most of the prominent honey-producers, but I have heard of only one bee-keeper who tells how to feed sugar for getting comb honey, which can be sold as honey. The one bee-keeper is Mrs. Lizzie Cotton, of Maine, and I protest against classing her among our honey-producers; and I protest, too, against calling her "some honey-producers," and against using the word *they* in speaking of her. Please say one of the bee-keepers, will you not, Mr. *Maine Farmer*? and instead of using the pronoun *they*, put it *she*, or else tell us who else in our broad land has ever publicly advised feeding sugar, and selling it for honey. Mrs. Cotton has replied to some of the charges made against her, but she has never yet replied to this one, nor has she changed that chapter in her book, that I know of. Will Mrs. Cotton please take notice?

WANTED A SITUATION.

A NOVEL ADVERTISEMENT.

OUR irrepressible friend Mrs. Chaddock asks us to publish the following. We would give it a place in the advertising columns, if there seemed to be any way by which she was going to make a speculation out of it. Here it is:

I want employment somewhere in the South, during the months of January and February next. I will work for my board. I would rather act as companion to some rich old lady, or be employed to read to some one; but I am not very particular. If I can't get either of those positions, my next choice would be to drive a mule team, and sell or peddle honey. I like a mule team first rate, they seem so light-hearted and free; but if a chance offers for me to sell honey for some one, I won't quibble about the kind of team. I can drive horses very well.

Then I should like picking oranges (are oranges ripe then?) and rolling them in tissue paper to send north, or I could feed pigs and pick geese, if no other work offers. The reason I want to go south is on account of my health.

If any one thinks of employing me, I will furnish references of good character and industrious habits.

MAHALA B. CHADDOCK.

P. S.—I would rather go to Florida. M. B. C.

Now I wonder if I am not Yankee enough to guess what you are up to, my good friend. Of course, when you get to driving that mule team, and selling oranges and honey, you will write to some of the papers, and tell us of the adventures you have. Well, we have no objections at all, providing your notes by the way are sent to GLEANINGS.

HEADS OF GRAIN FROM DIFFERENT FIELDS.

THE QUEEN THAT LIVED TO BE FIVE YEARS OLD;
MORE ABOUT HER, ETC.

YOU ask if I may not have been deceived in the queen reported to be five years old. Possibly I may by a young queen entering the hive and taking her place; but I have no idea that I was, for I watched her closely, and I think I should have known her from any other queen I ever saw. Her swarm did not dwindle. The only time I ever had spring dwindling in my apiary was when I lost 16 out of 32 by it. I bought her mother of a Mr. King, in Columbus, Ind. I do not know how old she was, but the hive was marked, "Commenced laying June 6." She remained in my apiary three years and ten months, leading out a swarm each year, dying 50 days after her last swarm issued. I bought her the last of September. Her wing was clipped, so I am certain she was not superseded.

Since you referred to it, I do remember having read Mr. Doolittle's statement, that "queens raised in a hive with an old queen are always good." I have now in my apiary an imported queen which I bought of Messrs. Charles Dadant & Son, in April, 1883, which must now be in her fourth year; and notwithstanding her long ocean trip she shows no signs of decay at this writing.

GLEANINGS, Sept. 1, 1885, page 587, first column, bottom line, read "mother" instead of "other;" second line from bottom, leave out "raised." The way it reads, it would imply that fall-raised queens are rarely superseded, but I intended to say that queens are rarely superseded in the fall.

Patterson, Texas, Sept. 15, 1885. E. S. ARVINE.

COMB FOUNDATION WITH LONG CELLS.

Why do not some of you bee-men get up a foundation-mill that will make cells longer one way than the other, for the surplus department, something like stretched foundation? as experience shows that bees never use misshapen cells for either brood or bee-bread, as also that they never put pollen in drone-cells.

We had honey-dew stored with such a strong resinous taste and smell as to be nauseating.

I have sections, regular size, $4\frac{1}{4} \times 4\frac{1}{4} \times 2$, as you term them, while what you call odd sizes, $4\frac{1}{2} \times 4\frac{1}{2} \times 1\frac{3}{4}$, sell readily. Reason, bees cap the honey more promptly, and it sells more promptly, being a more showy-shaped pound, although containing slightly less cubical contents. H. B. SPERRY.

Nokomis, Montgomery Co., Ill.

Friend S., we made just exactly the kind of fdn. you describe, in some of our earlier experiments, but we did it by accident, and because we could not do any better. The fdn. did work, too, a good deal as you mention; that is, bees would not put brood in it, and for that reason no one wanted it, and the rolls were broken up and worked over.—We suppose you make your section boxes larger while you make them narrower, so as to retain the weight at as nearly a pound as possible; but all the comb honey we are selling this season is in the usual $4\frac{1}{4}$ by $4\frac{1}{4}$, by a little less than 2 in thickness. Of course, they do not hold quite a pound; but instead of being an objection, it seems rather to please our customers better.

SPAFFORD'S DRONE-EXCLUDER.

I notice in last GLEANINGS a communication of my esteemed fellow-townsmen B. F. Spafford, describing his drone-excluder. I wish to say it does the work. I favor a modification of it—a very simple one, I herewith send you, which is a diminutive model. This gives two drone and two worker passages. In experimenting I found that the drones in trying to get out would so obstruct the passage as to greatly hinder and annoy the bees. I found, on removing the excluder, a row of drones all along the passage, and there would be a frantic rush by all to get out. The form I send can very easily be made of tin or zinc at a trifling expense. S. Y. ORR.

Morning Sun, Iowa, Aug. 21, 1885.

I will explain to the friends, that the little model sent by friend O. amounts to about the same thing as the Jones entrance-guard, only it is quite a little longer, and the ends are left open. The drones, being unable to get through the perforated metal, finally go out at the ends; but on coming back they try to enter at the usual place of the worker-bees. No doubt this will work all right, and obviate the difficulty mentioned. The only point to be determined would be the proper length. If made too long, the drones might not find their way out through the open ends; and if too short, they would get in where they go out. To determine this, many experiments will be needed. Meanwhile we extend our thanks to friend O.

WHY DID THEY SWARM OUT?

A few days ago, about 10 o'clock my little brother came running to me and told me the bees were swarming. Well, thought I, something's wrong. They were coming out of a hive containing a first swarm, hived June 11 on 8 sheets of fdn., the queen at least a year old, and having a crippled wing. I couldn't find the queen, high nor low. The bees all came back. Upon examining the hive I found that they had not more than a pound or so of honey in all, so I first thought it was starvation. But by removing the frames I found three solid full of capped brood, others containing uncapped larvae, lots of capped drone-brood (this was a frame of natural comb), and many queen-cells capped.

Now, what I should like to know is, were they trying to supersede the old queen, or was it starvation, or something else? I have but 3 colonies of my own, and 3 belonging to father, to attend to (am as yet an embryo apiarist). Five out of the six, including the one described above, have drones, or drone-brood; 3 have queen-cells started; none of them have half enough winter stores. They are strong in bees, having good prolific Italian queens, all but two being young. We have had a very poor honey season; not a drop of surplus. Bees have consumed stores in brood-rearing; plenty of corn pollen. Please tell me what's wrong, and what to do.

Chandler, Ind., Aug. 21, 1885. ALVIN L. HEINE.

Friend H., my impression is that it was the dearth of honey that caused the swarming-out. When no honey is coming in, and especially when none comes for a period of several weeks, bees oftentimes show strange freaks; and it is not infrequent for them to swarm as you describe, just because their stores are going daily, and are almost gone. They seem to get desperate, as it were, and want to do something, even if that some-

thing be jumping out of the frying-pan into the fire, as in your case.

QUEENS, VEXATIONS IN INTRODUCING.

I am just a beginner in bee-keeping, yet I have had my share of trials and vexations already. I should like to inquire what causes my bees to act so unreasonable when I am trying to introduce a new queen. I keep Mrs. Queen caged 48 hours; and if the bees act rough toward her I cage her again; and then, if they act kindly, and accept her, I release her. On three different occasions this season they seemed to accept the strange queen; but in the course of five or six days I would find them fighting and stinging each other in the same hive. They have kept this up for a week or ten days. I have opened the hive and found them balling or hanging to the queen's wings, legs, etc., and they finally kill the queen. Then I have taken a frame from another hive, with bees and queen, and given them, and they would accept her. What can I do in such cases? It is discouraging to lose so many valuable queens. H. M. PARKER.

Plymouth, Ohio, Aug. 18, 1885.

Friend P., I can not say why your bees act thus, unless it is because of a scarcity of stores. During a protracted dearth of honey, bees often act in just the way you mention. Feeding will probably remedy the trouble, providing you use care, and don't get any robbing started. Perhaps you have found out the remedy already.

WINTER ENTRANCE FOR BEES WHEN PACKED IN BOXES.

In packing bees for winter in boxes, how large ought the opening to be from the entrance of the hive to the outside of the box? S. K. FUSON.

Rockville, Ind., Sept. 17, 1885.

Friend F., I would have the entrance on the inside $\frac{1}{2}$ inch in width, in order that we may exclude mice. The length is not material, but I would have it as much as eight or ten inches, in order to give a good air-space. We have found, by careful experiments, that our bees winter better with the entrances to our chaff hives open full width than where contracted.

WORKERS THAT CAN'T FLY: 50 LBS. OF HONEY BESIDES THE INCREASE, FROM ONE POUND OF BEES.

I received a queen with 1 lb. of bees from Louisiana—a good prolific queen, only hundreds of the workers can't fly. They look all right, only they spread their wings when they crawl around, and have not the power to fly. They leave the hive when a few days old, and die a few feet from the hive, in clusters, and scattered here and there. Said queen is superseded. They had a young queen laying 14 days, and I put the old queen in a hive, and she is laying finely. The one pound of bees have made, to date, 51 lbs. extracted honey, and I have taken away four frames of brood, and they are heavy now. E. E. SMITH.

Clayton, Mich., Sept. 11, 1885.

CLEANING SMOKER-TUBES: SOMETHING FURTHER ABOUT IT.

I have read in GLEANINGS of several different ways of cleaning the Clark smoker, so I will give you my way. Take a large wire, about a foot long; make a loop on one end for a handle, and bend the other so as to fit the pipe of the smoker. Every time this wire is used, the end that fits the pipe should

be heated quite hot. As the wire is inserted, the heat will soften the gummy matter so that the pipe can be cleaned very easily. I prefer heating the wire to any method I have seen yet. Also a word in regard to fuel. Rotten wood is good, but hard to get. Rags emit a disagreeable odor, and gum the smoker. I keep, in the center of my apiary, a box full of small chips from the dooryard, and I find that they burn as long, make the hottest fire, and keep the smoker the cleanest, of anything I have used yet. Wood of any kind burns well in a smoker; if dry, we need not be particular about it.

Lone Tree, Ia.

ROWLAND SHERBURNE.

A DAILY RECORD OF ONE COLONY: 134 LBS. OF HONEY IN ONE WEEK.

My swarm on Fairbanks scales gained, July 17th, 16 lbs.; 28th, 17 lbs.; 29th, 17 lbs.; 30th, 18 lbs.; 31st, 23½ lbs.; Aug. 1st, 24½ lbs., an hour before they stopped work, when I extracted them; they would have gained 2 or 3 lbs. more by dark. Aug. 2d, 17 lbs. I weigh and balance them every evening, making 134 lbs. gain in a week, and no mistake, in a two story chaff hive, and I divided them in June. I have extracted, so far, 3150 lbs. basswood, and not over yet, but drawing to a close. I have taken off no sections yet; have regained my loss in bees in wintering and springing. C. G. DARLING, 40—80.

Lincolna, N. Y., Aug. 3, 1885.

BEES IN LOUISIANA.

My bees are doing their level best; the honey is dark, for which they are not to blame, but it is very clear and sweet, with a fine flavor.

The "New South," as our Northern friends call it, is looking up here. Our cotton, corn, and small-grain crops are splendid. The cotton is yielding largely this year, and I shall have some of the honey saved separate. The blue and white water-pepper is beginning to bloom, and is yielding well. The ever-blooming elm is also full again, and bees are swarming on it.

About eight miles from us is a place where buzzards roost, and they have killed the trees for acres and acres. A man near us cut five trees in one day with bees in them, just around the buzzards' roost, and he says that just when the buzzards commence alighting on a tree having bees in it, the bees leave it and go to another, and that he can count 100 trees on ten acres, with bees in them. The neighbors cut a bee-tree near us last Saturday, and on Sunday the bees came to me. I think my honey-gatherers led them home. I put them in a hive, and they are doing well. ST. J. T. MOORE.

Monroe, La., Aug. 9, 1885.

We are glad to hear so good a report from you, friend M.; but I can't quite understand why there should be bee-trees where the buzzards roost, unless it is because there are more dead trees, and therefore more hollow trunks. But, why is it that the buzzards kill the trees? Is it because of the unpleasant smell they carry with them?

DO MARTINS EAT BEES?

Will you kindly give me your opinion on the following question? I have a fancy martin-box in my yard, in which 12 or 15 birds have made their homes, and are rearing their young, and my neighbor has several colonies of bees which he claims are suffering through the depredations of my birds. He claims that they carry off his bees to feed their young, and asks me to destroy the birds. I think a

great deal of my birds, and do not wish to sacrifice them until the fact is fully established that they are an injury to my neighbor. The birds are company for me, and are also useful in keeping the hawks away from my poultry. I know professional bee-men in Ohio (my native State), and also in this State, who keep martins on their premises, and it strikes me they would not do so if the martins ate their working bees.

A. V. LYLE.

Cline, Texas.

Friend L., I am sorry to say that martins do sometimes learn to eat bees; and, for that matter so do common fowls occasionally. It seems to be an acquired habit, like hens eating tomatoes, cucumbers, and the like. Sometimes, when short of food, they get the hang of it and remember it as long as they live; and then, again, they never notice them at all. I would try placing plenty of such food as the martins prefer, where they can get it conveniently, and may be they will give up bees. When any of the feathered tribes, however, discover what a sweet morsel a heavily laden bee is to the palate, it is not so easy to get them over it. Perhaps when the bees cease gathering honey, and stop tumbling around their hives, heavily laden, the mischief may cease.

HOW TO MAIL QUEENS SAFELY.

Many of our friends north ask for our secret in always sending queens safely. Our losses up to July 30th were one-fourth of one per cent. We use well-ripened honey (ripened in the hive), and pure pulverized sugar. Make it so that it will not run—not too thick. Make it as you need it for *each mailing*, and mail the queens as soon as the cages are ready. Send out no queen that is not a good layer, as this is the proof of health and condition. Use precaution in caging; be very careful in handling her majesty. We rarely touch her. Do not use the smoker. We use the Peet cage for mailing, and send from Oregon to Maine without loss, other than delay, or, we should say, astrays. J. W. K. SHAW.

Loreauville, La., Aug. 13, 1885.

RETAILING EXTRACTED HONEY IN WALNUT SHOW-CASES.

I have had a great many large show-cases, built of walnut and ash, to hold a large quantity of box honey and ornamental tumblers of extracted, and have placed them in the principal stores throughout the city, and they keep account of what they sell, and settle whenever I say so. They seem to prefer this plan rather than paying cash for a single crate of 18 boxes; because whatever they can not sell I have agreed to take back, and they receive their percentage on what they sell. But this plan has almost blocked out all the sales of all the small bee-keepers who used to sell small quantities for cash. They, of course, don't like my style of doing business; but my aim has always been to be ahead in the honey line, although I find myself behind in some others.

J. C. SIMMONS.

Pottsville, Pa., Sept. 4, 1885.

IMMATURE BROOD; WHY DO BEES CARRY IT OUT?

Will you please tell us what makes our bees uncap and carry out of the hive hatching brood from new combs on foundation? They are strong in bees, have plenty of honey and brood in all stages, and no signs of moth worms in the hive.

Quincy, Mich., Sept. 4, 1885.

M. J. RAWSON.

The above question has been answered

quite a number of times this fall. I know of only two causes to produce such results. The first is, scanty stores, or, in other words, starvation. As a last resort, the bees will uncap the larvæ to suck the juices, and the lifeless bodies will be seen scattered around the entrance. The other cause is the work of the moth. The moth worms often tunnel under the bodies of the brood; and the bees, in their efforts to dig out the mischief, will sometimes tear considerable brood, sacrificing the life of some of their offspring, as a last resort to save the life of the whole colony. I have never known this sort of trouble to be worse on new combs of fdn., but usually to the contrary.

DOES A FERTILE QUEEN EVER LEAVE THE HIVE, EXCEPT AT SWARMING TIME?

Would the queen I got last spring leave the hive and go to another, eight feet away?

Azle, Texas, Sept. 11, 1885. O. L. KIMBROUGH.

Friend K., this question has been discussed quite a little in some of our back volumes. As a rule, a fertile queen never leaves a hive except with a swarm; but there seem to be some exceptions to this rule. Thus, queens have been found in a hive several feet away, without any apparent explanations in the matter. We once found the queens had changed places in two hives, about the distance apart you mention. One of them we knew, because both of her wings had been clipped entirely off. Such changes are sometimes made while extracting, the queen being carelessly shaken in front of the hive, and by mistake crawling into some other one instead of her own.

CARNIOLAN BEES, AND HOW TO DISTINGUISH THE CROSSES.

I concur with the article by Dr. E. K. Blanck, on page 596 of GLEANINGS, but I now feel safe in saying something more of Carniolan bees. You ask how we shall distinguish crosses with our native bees. I answer, by their behavior, if not by color. I have not seen a cross by native drones; but whenever we get in any bees the disposition of unrest belonging to our native race, we will reject them. Carniolan bees are not disturbed by lifting their combs from the hive; and I believe it will be found that their cross with blacks will be a very much better race than the cross of Italians with blacks.

Another point I make for Carniolan bees is, that they are more readily gotten off the combs and sections when you want them off. This trait will commend them to all, for it is a matter of importance when robbers are around thickly. They again differ, as widely as can be, from our black bees, when shaken off the combs, in not flying around, but at once crawling into the hive again. Carniolan queens, when mated with Italian drones, produce some beautiful bees, some having three bands and some none, but all with the gray or white bands of down, behind the yellow bands. I send you a cage with some of these bees. I have finished requeening my whole apiary of 62 colonies with Carniolan queens. I repeat, let us choose queens on account of their quality, and not on account of their dress.

S. W. MORRISON, M. D.

Oxford, Pa., Sept., 1885.

Thanks, friend M., for the cage of bees, and for your suggestions. I agree with you

in regard to the importance of choosing queens on account of their honey-producing qualities, rather than on account of any accidental stripes they may possess.

IS THE WATER-OAK HONEY INJURIOUS TO BEES?

I have a small lot of bees, only 24 stands. The bees in this section of country gathered honey from the water-oak. It is not fit to eat, and I am much afraid it will injure the bees. If you can tell what is the cause, let it be known through your journal. There is no one in this section who can tell the cause. They gathered that stuff in the month of May last year.

F. B. FULKERSON.

Barnard, Kan., May 31, 1885.

Friend F., I think the honey you mention must have been the product of aphides.—There has been considerable said in our back volumes in regard to honey from the oak. Some of it is unpleasant, like that you describe, while other specimens rank very fair. I should dislike to go into winter quarters with stores of such honey as you refer to.

THAT BEE-DISEASE, AGAIN.

Will you please inform me what ails my bees, and what shall I do to cure them? In March, two stands of Cyprians commenced dying off, and at this time all of my Cyprians, Holy-Lands, and Italians, are afflicted. They get black, and have a shiny or glossy appearance, also a jerking or tumbling movement, and they nearly always get on their backs to die. I have 41 black swarms, and they are not diseased. I have perused your A B C book, and you said at that time, when it was printed, that you did not know any cause, and that you had had only one swarm that was diseased, and that you put it with another, and that it came out all right.

C. K. DECKER.

Hanford, Tulare Co., Cal., June 8, 1885.

Friend D., the only remedy I have ever found is to destroy the queen and put in a new one, as mentioned in the A B C book, and I have never yet known a case of failure. From this it would seem that the disease is something inherited from the queen. A new queen produces new bees, and these new bees don't seem to be subject to the malady.

HORSEMINT HONEY.

I am perfectly astonished at the large honey-dealers of the North. I am all out of patience with them. I don't know why they could be so prejudiced against horsemint honey (for it certainly is nothing more nor less than a prejudice). The plant itself has a nice odor. Some people make tea of it to drink, and it is a good medicine for summer complaints. Now, why not have good honey from it, I'd like to know? It is just like giving a dog a bad name, and he is sure to go by it. Horsemint honey is almost always gathered in a dry time, and is generally thick and nice, just from the hive. There is a sad mistake about it, some way or other. I think it is the mildest honey that is raised in the South.

Bracken, Tex., Sept. 2, 1885.

N. J. W.

Friend W., the most of the horsemint honey that has been put on the market was not sufficiently ripened, and as a consequence it had a rank taste that few people would call pleasant. Give us a nice article thoroughly ripened, and I think it will rank fairly by the side of any we have. The honey itself should be able to overcome the prejudice.

TROUBLE IN REMOVING WIDE FRAMES.

I want to give you a little of my experience with section boxes and frames. I was taking some honey lately, and found my wide frames all fast. The space between the upper and lower frames was all filled with honey; and in trying to get the first wide frame and section boxes out, the frame and some of the boxes pulled to pieces, so I about came to the conclusion to abandon the section boxes, if I can't find some remedy. I found my narrow frames with comb built from one to the other, and they had to be cut apart to get them out. What shall I do about it? I have thought I had better abandon the section boxes and use only the narrow frames.

REV. E. C. COX.

Centerville, Leon Co., Texas, July 21, 1885.

Friend C., the Heddon honey-board remedies the trouble you mention, of attachments of comb to the wide frames, or to the cases containing section boxes. The reason why you found your narrow frames built together solid was because your bees had their hive full, and hadn't room to store their surplus. Give your bees more room, and look them over oftener.

SPAFFORD'S DRONE TRAP.

I see you have Spafford's drone-excluder in your last issue. I tried one on the same principle this season, and it did not answer, because it blocked the entrance for the worker-bees; the drones being heavier than the workers, they stopped all ingress; but my trap does away with that difficulty.

Elora, Ont., Aug. 28, 1885.

G. STRANGWAY.

Thanks for your report in regard to the drone-trap, friend S. I will explain to our readers, that the one you describe is essentially the same thing as figured in our pages a year or two ago, and described in the A B C book. I think the difficulty with the Spafford drone-trap can be obviated by making more openings for the worker-bees.

WILL MAPLE SYRUP ANSWER FOR WINTER STORES, ETC.?

Will you please tell me, through next GLEANINGS, if maple syrup, tintured with tartaric acid to prevent crystallization, will do to feed bees on for winter stores, without giving any bad effects, such as dysentery?

T. H. WHEATLEY.

East Brookfield, Vt., Sept. 18, 1885.

Friend W., tartaric acid would do no hurt, for it has been repeatedly used to prevent granulation of cane sugar; but I am afraid that the maple syrup you would be apt to find would hardly be sufficiently free from foreign matter, such as maple syrup always contains, to render it a safe feed for winter stores. A nice article of maple syrup would answer, without doubt; but if you have a nice article you surely can not afford it for your bees, for it would command, in almost any market, double or treble the price of a syrup made of granulated sugar. Any sort of sugar must be pretty nearly chemically pure, to be proper food for winter stores, and the granulated sugar of commerce is, as a rule, the cheapest of any you can get for the purpose, for it is refined in a wholesale way, so that the cost of getting it in a remarkably pure state is comparatively trifling, while the maple syrup usually to be obtained, and, in fact, all other kinds of syrups, in-

cluding honey itself, as the bees usually gather it from the flowers, contain a vast amount of foreign substances, which are quite likely to make it unfit for such a diet as the bees require when kept for months in confinement as they are during the winter.

Inclosed find a piece from the New York *Sun* of August 3d. It may be well for you to keep track of that station, to inform your readers.

Bees are making but little honey this summer. They are at work on buckwheat now. We shall get but little honey from it, as it will be a short crop.

GEORGE RICHARDS.

Harpersville, N. Y., Aug. 11, 1885.

EXPERIMENTS IN BEE CULTURE.

An agricultural station has recently been established at Aurora, Ill., in connection with the entomological division of the Department of Agriculture. Mr. Nelson W. McLain has been appointed to take charge of the station, and Prof. Riley has instructed him to pay particular attention to these subjects:

To secure the introduction and domestication of such races of bees as are reported to possess desirable traits and characteristics; to prove by experiments their value to agriculturists of the United States, and their adaptation to our climate and honey-producing flora; to make experiments in the crossing and mingling of races, and endeavor to secure the type or types best adapted to the uses of our bee-keepers; to make experiments in the methods of artificial fertilization; to test the various methods of preparing bees for winter; to gather statistics concerning the bee-keeping industry in the United States; to make observations concerning varieties of honey-producing plants for bee-forage; to study the true causes of diseases yet imperfectly understood, and the best methods of preventing or curing them; and to obtain facts as to the capacity of bees to injure fruit.

WILL IT PAY TO FEED BEES DESTITUTE OF STORES?

My black bees have not honey enough to take them to mid-winter, except about three stands. All my Italians, the new swarm or colony, will have to be fed. One colony (new) has not one ounce of honey. Will it pay to feed enough to them, while the weather is warm, to winter? How much sugar to a colony? This season has been very poor for honey here except a week or so during the bloom of basswood. Lots of buckwheat here, but it doesn't furnish honey.

W. S. JONES.

Central Station, W. Va., Sept. 8, 1885.

I suppose, friend J., circumstances will have to decide the matter to a certain extent; but I should say it would most assuredly pay to feed bees; and for myself I would feed them, even if it did not pay—that is, unless I had found by experience that bee-keeping was a much poorer business than any reports we have had yet; at least, I feel sure it will pay in the end instead of letting them starve. You may not get your money back the first season after feeding, but this is true of almost any farm crop. I can not answer the question as to how much sugar per colony, any more than a farmer could tell how much it would cost to feed a cow through the winter; but as a rule we might say from 15 to 20 lbs., if feeding is commenced this month.

WILL THE CLARK SMOKER BURN CHOPPED-UP CORN-COBS?

Please let me know if your Clark smokers will burn corn-cobs that have been ground on a feed-mill, into pieces the size of three or four kernels of corn, and dried in the oven. I think the chaff and

small pieces of cob blown from the large corn-shell-crs would be good fuel, but have never tried it. Corn-cobs prepared as above burn well in the Bing-ham smoker.

GEO. M. THOMSON.

Grand Junction, Ia., Sept. 11, 1885.

The Clark smoker would be a rather poor affair, friend T., if it would not burn such fuel as you mention. Corn-cobs make a large volume of smoke, and for a time it was thought to be the best fuel that could be procured; and the only drawback is, that it contains a much larger quantity of tarry matter than rotten wood, and many have discarded it because it fills up the tubes of the smoker so quickly. I should think that the chaff and small pieces of cob you mention would make splendid fuel.

WHY DO BEES ABSCOND FROM THEIR HIVES?

I should like to ask you concerning some dissatisfaction among my bees. One of my Italian queens came out this spring, carrying with her all the workers that were able to fly, leaving the brood-chamber full of brood, from that hatching, down to eggs, with some little storage. Soon afterward another one of my Italians came out of her own hive, bringing with her all the bees in the hive, and went in the hive the first had left, and stayed till next day, when they came out and settled. I caught the queen and cropped her wings, and put them back in their own hive. She seemed to be very badly dissatisfied, and the bees came out for three or four successive days and would settle, and in a few minutes would go back. On examination I found they had lost their queen, and found they had exhausted their stores. I gave them some stores, after which they went to work and reared a fine queen, as they had a good supply of eggs, and are now doing well. This crazy way of doing puzzled me very much, and I shall be very thankful if you or some of the friends would give me some clew to it and remedy for it. My bees are not gathering much honey yet, on account of too much rain, but they seem to be gaining rapidly.

J. W. SEGLER.

Paris, Texas, July 6, 1885.

Friend S., this matter is fully discussed in the A B C book, under the head of "Absconding Swarms." In your case they absconded because of scanty stores. This they are especially apt to do in the spring. A good many times they go off with a little honey left in the hives, as you mention.

ADULT BEES CAN SECRETE WAX.

Can working bees secrete wax? I see that W. Connelly takes the ground that bees old enough to be workers can make no more wax (page 164). I just feel like saying a word, and will give you a case that I know to be a fact. One hive of bees swarmed, and the swarm was hived in the usual manner. That swarm filled their hive full, and swarmed in just 23 days. As it takes 21 days to hatch a bee from an egg, this last swarm were the same bees as the first swarm, and they had been workers for 20 days. But they filled up the second hive with comb and honey. It took three weeks to fill the last hive, so those bees old enough to be workers did secrete wax, and build comb for six weeks.

E. FRANCE.

Platteville, Wis., Aug. 24, 1885.

Will the friends who claim that old bees can not secrete wax please answer friend F.?

SYRIO-ITALIANS; A WEAK COLONY WITH A LAYING QUEEN AND QUEEN-CELLS.

I have been requeening my apiary this year with Syrio-Italians, raising my queens from my best Syrian stocks; and by keeping down the drones in my Syrians, and allowing the Italians to raise them, I think I shall have most of my queens mated with Italian drones. I like that stock very much. They cap the honey very white, and are ready to go into the sections whenever the honey-flow will warrant them, without the coaxing so often necessary with the Italians. They are quiet to handle, are very good honey-gatherers, and the queens are good layers, and easily seen on the comb.

I had a singular experience with one colony. I removed the queen and made a nucleus with her, in order that the colony might raise queen-cells. Ten days afterward I cut out all the queen-cells and returned the queen to the old colony, and with her a frame of bees with brood and eggs. Some days after I looked into this hive to see that she was all right, when, to my sorrow, I found queen-cells started, and almost ready for capping on the frame returned with the queen. I at once concluded the queen was killed, and looked no further. When those queen-cells were ripe I went to the hive and cut them out; on looking further I found frames of eggs, hatching larvae, more queen-cells, and my queen also. The colony was not strong enough to want to swarm, then why these queen-cells? The queen apparently had not laid any eggs for three or four days after being returned to the hive.

J. SINGLETON.

Brooklyn Village, O., Aug. 21, 1885.

It would seem, friend S., that the bees had forgotten their old queen to such an extent that they kept on with their preparations for rearing a new queen. I have observed the same thing once or twice, and I should consider it a little risky to let a queen loose without caging, after she had been away from the hive for ten days. You will notice, that by the operation you succeeded in getting queen-cells built while the hive had a laying queen. I have also done the same thing under the same circumstances.

A FAIR REPORT FROM TEXAS, ETC.

The honey season of 1885 here in Central Texas has been generally unsatisfactory. My home apiary did very well on horsemint alone; later on it made some honey from honey-dew, and the last of August the upland elms bloomed, but the flow was for only a few days. Bees now are working on goat-weed and broom-weed. By the way, a good plant of broom-weed makes the best brush I have seen for brushing off bees from the combs.

From 100 colonies this season I have taken 1500 lbs. of honey, and left plenty to winter on.

I have never seen any mention of the *Texas Bee-Keeper* in GLEANINGS. It is run by the Common-Sense Bee-Hive Co.

I use only the A. I. Root Simplicity, and in my varied experience I have never found its equal.

WM. WRIGGLESWORTH.

Crawford, Texas, Sept. 16, 1885.

Friend W., I have not mentioned the *Texas Bee-Keeper*, for the very reason you give. The man who has been for several years running the Common-Sense bee-hive has been in such bad repute that I could not consistently say any thing good of him, and

so I said nothing in regard to the publication. If I am any way at fault in the matter, I am glad to be corrected. If the man has turned over a new leaf, we most assuredly bid him God speed.

SOUR HONEY AND MOLDY COMBS; WHAT CAUSED IT?

On the 21st ult. I went some three miles to a friend's to look over his bees and take honey in one of the colonies. The honey not sealed was sour; also the pollen and combs were moldy. The bees seemed lively and healthy. There were eggs, hatched larvae, and sealed brood. The 22d of June there issued a large swarm from the above hive, so there could be no hatching bees at the present writing. Please tell us what to do with them—cut out all the moldy and spoiled combs, or let them alone?

JAMES A. KIME.

Fairfield, Adams Co., Pa., July 25, 1885.

Friend K., I have never in my experience found a case like the one mentioned, where a good colony of bees wouldn't make sour honey sweet, and bring it out all right. I would just let them go ahead, so long as they seem to prosper and do well. Perhaps it might be well to cut out the moldy pollen, although I believe the bees will fix that, if they haven't too much of it on hand at one time.

A BALLED QUEEN LIBERATED BY BEING PLUNGED INTO WATER: MARTINS KILLING BEES.

The queen and bees came Friday evening. I put them in Saturday morning. I looked at them in the evening, and I saw that they didn't like her; three workers were dead. I put them back till the next day noon, and looked again and found her balled. They had cut under to her, so I dropped them into some water and got the queen all right, so I took a cage four inches square and put her back on hatching brood so she would have company. I looked the next day, and found twenty or more young bees with her, so I made a small hole in the comb, set them back, looked in the next morning, found no queen under the cage nor in any other place—no eggs—so I put some eggs in on the 23d. This morning, the 23d, I found four queen-cells started.

I have some as fine Italian bees, I think, as can be found anywhere. I got eight out of nine through the winter. My melon-juice and sugar were all right for wintering. Bees are not doing much just now. I have lots of melons. Come over, and bring Huber and the girls. I am getting 20 cents for my honey. I have 17 colonies now, 2 Italians. I lost 4 young Italian queens this summer, and 2 blacks.

The bee-martin is bad here. I have been using my gun. I didn't think they did any harm till I saw them catching drones, and I think they got the queens also.

J. AVERY.

Michigantown, Ind., Aug. 23, 1885.

DO NOT SEND HONEY TO THE CITY; CREATE A HOME MARKET.

I want to say a few words to the brethren about selling honey. It is certainly a bad plan to send your honey to the city. We want to get the people to eat honey, then we shall have a market for it. As it now is, not one family in a hundred buys honey for family use, and only a very few keep it for visitors. Now, are we likely to get them to eating honey by sending it to Chicago, St. Louis, or any other city, to be piled up in the commission room

and reported dull sale, or no sale at all? Why should it sell? What's to make it sell? Too much honey for the city, and no orders from storekeepers in the country, for fear it will be smashed up on the road. As a consequence, honey is a stranger to most folks. Now, in a few words I should like to encourage my bee-keeping friends to sell their honey at home as much as possible; for if we don't, worse times await us. A. LINDLEY, 42—98.

New Providence, Iowa.

QUESTIONS IN REGARD TO PREPARATION FOR WINTER.

How much sugar would you put to a quart of water, if you feed this month?

Do you think it best to feed at present, or wait until packed for winter?

I agree with Dr. Morrison, about this being a very bad year for bees in Pennsylvania. I have taken 800 lbs. of honey from 25 colonies. I know that you were very successful last winter, and that is the reason I send to you.

I have been using granulated sugar from Franklin Refinery, Philadelphia; and when the syrup is left in a vessel, a blue substance settles like indigo. It does not poison the bees.

Dilworthtown, Pa.

HENRY P. FAUCETT.

The amount of sugar for a gallon, as given in the A B C, is 25 lbs.—I would commence feeding at once; and as we use chaff hives altogether for wintering, our bees are already packed, except putting on top cushions.—I have never seen the blue substance you mention, in a syrup made of granulated sugar. I presume it is something that got in by accident during the refining process, and is probably in no way deleterious.

AN ENCOURAGING REPORT FROM FRIEND HEDDON.

As you will see by the inclosed railroad receipt, I have shipped you by freight a 50 and 100 lb. keg of basswood honey, such as always brings orders for more. If you want any more of it, order at any time, and place to my credit. Accept my thanks for your very kind and liberal notice, which I appreciate. My ten tons of honey will all be gone in sixty days, I think.

After losing three-fourths of 476 colonies, I was called rash for investing \$700 in bees last spring; but over \$1600 worth of honey, and 450 colonies, has rewarded my courage.

JAMES HEDDON.

Dowagiac, Mich., Sept. 21, 1885.

If I am correct, the above was not intended for publication; but I have taken the liberty of using it, and it is just the kind of reports we want. Tell us in a few words, friends, what you have to encourage you in continuing to be bee-keepers.

IDENTIFYING ROBBERS WITH WHEAT FLOUR.

I have a few questions to ask. I am a beginner. I had a misfortune last Sunday. I was away from home, and when I got home my folks told me that there were some robber-bees at our hives. I went into the apiary, and found one swarm flying very fast. I went across the road, and found one of my neighbor's swarms flying very fast also. He denied that they were robbing. I went back and sprinkled flour on them, and they went into his hive, so I shut mine up till next day noon. I opened them a little. I had my hive open half an hour, then his rushed in and began carrying out the honey. I shut my

hive, then they clustered again on the opposite side. I took a bunch of straw and burned them. Did I take the right way to get rid of them? If not, please tell me what I should have done.

Indian River, N. Y.

MICHAEL ZEHR.

Friend Z., your plan of proving that the robber-bees belonged to your neighbor's hives is a good one, and it was quite right and proper to give him proof that they were his bees; but you had no more right to kill them than you have to kill your neighbor's cow or horse if it should come into your doorway or garden. There are many easier ways of stopping robbing than by killing the robbers. Any of our text-books on bee culture would direct you how to manage. I should say that neither your neighbor nor his bees were any way at fault—that the fault was yours in permitting a hive of bees to remain in condition where it would not repel robbers. They were probably queenless, or the entrance was much too large for the number of bees in the hive, or something of that sort.

MRS. CHADDOCK'S LETTER.

She Tells us How to Make Good Mucilage at an Expense of Only Five Cents for Half a Gallon.

SHE ALSO TELLS US SOMETHING ABOUT OUR GOOD FRIEND E. A. GASTMAN, OF DECATUR, ILLS.

MR. ROOT:—You say in your price list that you do not see how people can afford to make mucilage and sell it for five cents a bottle, and throw in a brush. I think I can tell you how. This summer I attended the teachers' institute in Lewistown, Ill., and our instructor in the reading-classes was Mr. E. A. Gastman, of Decatur, Ill. He has been for 25 years principal of the city schools in Decatur. He is also a practical bee-keeper, having at the present time some 75 colonies in the city. Mr. Gastman is a funny man. I have known men before who could be funny for an hour or two, but never before saw one who could keep on saying funny things for two whole weeks, and not run out. One of the things he said was, that "some people are not all alike." He writes bee-articles for the *Illinois State Journal*. Perhaps you know all about him.

Well, one day he told us how to make mucilage, and we all wrote it down in our scratch-books. He said we could make half a gallon for five cents. Take five cents' worth of gum tragacanth, add warm water to it, a little at a time, and let it swell. Add a little pulverized alum, to keep it from molding. If wanted dry on paper, like postage-stamps, add a little glue; and if wanted to paste labels on specimens—stones, for instance—add a little sugar.

MAHALA B. CHADDOCK.

Vermont, Ill., Sept. 18, 1885.

Thanks, Mrs. C., for your recipe. I think it is exactly the same that I used years ago in preparing objects for the microscope. If I remember correctly, it is apt to sour unless something is put in to prevent. May be the alum would do that; if not, I would add a little carbolic acid. Gum tragacanth needs to be soaked quite a while before it forms a mucilage.

REPORTS DISCOURAGING.

REPORT OF THE HONEY SEASON IN WESTERN NORTH CAROLINA.

WE are one of your A B C scholars, and saw a letter in last GLEANINGS from Henry Stewart, which rather goes back on us natives of the mountains of Western North Carolina, about energy, and making this a great land for honey. We have a great many honey-plants here, to be sure; but the honey is not in them by the quantity, or the old blacks can not get at it. My father has had from 25 to 60 stands for the last 15 years, and I do not remember that he ever got more than 50 lbs. surplus any season from his best stand, and I think 75 lbs. is the best I have heard of from any one stand in this county. Now, the point Mr. Stewart writes from is about 50 or 60 miles west of here, but about the same kind of a country as this. It is on the same range of the Blue Ridge. Now, you can see from my report how honey has flowed here this year. I have invested about \$50.00 in improved bee-fixtures—every thing that would help them out that I saw in your catalogue—your hive, frames, section box, foundation, and about every thing that would be of any service to them, and have not got 25 lbs. of surplus honey, and some of my bees are without honey now, and will have to be fed from this till spring, or starve. Some few may have enough to carry them through till spring. I know of two other lots, of about 15 hives each, that have not got 50 lbs. of surplus each this year. I commenced in the spring with sixteen; lost one and doubled back to 12, and bought one four-frame nucleus. Now all that I have for my investment is three stands of Italians from my four-frame nucleus, and I have raised and introduced 8 Italian queens, and think I shall get three more, and have all in Simplicity hives but four. But still I will not go into Blasted Hopes yet, as this has been one of the worst seasons for honey that I ever have seen in this country. I do not think there is one-tenth the honey made here there is in a fair season. I have been in our town, Asheville, from once to five times every week for the last four months, and have heard of but one lot of honey offered for sale there. I have never seen my bees come in with large loads at any time, except when locust and sourwood were in bloom, and but for a little while then. I can not see the cause for honey being so scarce this year in this country; but it is not in the bloom; or if it is, the bees did not get it out.

R. L. PATTON.

Best, Buncombe Co., N. C., Sept. 17, 1885.

THE NAMELESS BEE-DISEASE: A RATHER DISCOURAGING REPORT FROM AN OLD FRIEND.

Inclosed please find 75 cts. for GLEANINGS for nine months. Don't send it any more, as I am not able to take it any longer. Put me in Blasted Hopes again. Three years ago I got from 70 colonies over 11,000 lbs. of honey; two years ago from 97 colonies, 5000 lbs.; last year, 1100 lbs. from 99 colonies. This year from 160 colonies, 2000 lbs. I gave all of my time to my bees, and am most dreadfully discouraged. I have had, this entire season, black shiny bees carried out, seemingly in distress. They could not fly, or scarcely fly; would go back, and be again carried out. The trouble extended to a large

part of my bees. Some dwindled while others kept up. As the queen was very prolific, the trouble is nearly stopped, save one hive which is dragging the shiny fellows out. I am greatly alarmed; for if winter weather should assist the trouble, I believe all the bees would go.

One man here, out of 215 colonies lost all but 19 last winter, and his bees were afflicted the same; but he thought the black shiny bees were old and dying bees; but I know better, as it does attack young bees also. I know whereof I speak. The brood is all right in the comb. The California friends called your attention to the trouble, but you passed it lightly, referring to the A B C book. I have lost bushels of bees during the summer, in the way above described.

A. L. KLAR.

Pana, Ill., Sept. 21, 1885.

I beg pardon, friend K., but I did not mean to pass the matter over lightly, as you term it. So far as I know, nothing has been brought to light in regard to the malady, further than is given in the A B C book, and it seems hardly worth while to repeat what I have given there. Have you and your friends tried a new strain of blood in your apiaries—that is, giving a new queen, and rearing queens from her? I shall be glad of any facts in the matter that will help us to manage the trouble.

This has been a very poor season for bees and honey. From ninety hives, spring count, in good condition, I have taken only about 1200 lbs. of comb honey, and shall perhaps return some of it, as some hives will probably be too light for winter, without help. Honey is selling here in comb for 10 and 13 cts. per lb. California honey injures our market.

MRS. R. A. NORTH.

Shellsburg, Iowa, Aug. 29, 1885.

HUMBAGES AND SWINDLES PERTAINING TO BEE CULTURE.

MORE ABOUT MRS. COTTON.

AS quite a number of my friends in this vicinity have been humbugged and defrauded by purchasing hives and bees of the woman named below, I send you the inclosed slip, to keep her methods before the public.

Andover, Mass., Sept. 14, 1885. L. H. SHELDON.

Below we give the newspaper item which our friend sends us:

I read in the *Tribune* a quoted paragraph about Lizzie E. Cotton, saying that she took \$20 from a poor one-armed woman and sent in return "part of a hive containing few bees and no queen." She served us precisely the same way, and we threatened to sue her for damages, but could not spend time to follow the matter up. But can not this contemptible fraud be stopped? Her method is to work in certain sections until too hot for her, then steal away to another, answer no letters, but ply her swindle as before.—H. M. Holmes, Orleans, Mass.

I presume friend Sheldon would furnish the details of the way in which these friends have been humbugged, if it were necessary; but the matter has been gone over so many times at length, that it will hardly be advisable to repeat it in detail. Newspaper editors who are receiving and inserting her advertisement should look into the matter.

DOES IT HURT A QUEEN TO BE CRIPPLED IN ONE OF HER LEGS, ETC.?

ALSO SOMETHING ABOUT MAKING POSITIVE STATEMENTS WITHOUT POSITIVE KNOWLEDGE.

I RECEIVED from you, Sept. 2d, a "select tested" Italian queen, and Sept. 4th I received an untested queen. The select tested queen I introduced to a colony that had been queenless 9 days. Having removed the queen 9 days previous to the day when I received the queen, I removed the queen-cells which they had built, and caged the queen on a comb over sealed honey. After a period of 24 hours I lifted the comb from the hive and cut a hole from the opposite side of the comb through into the cage, leaving the loose piece of honey for the bees to remove, and liberate the queen after the comb was returned to the hive. After a lapse of two days I again lifted the comb from the hive, to be sure that the queen was liberated. I found that she had commenced laying, as I found eggs in the comb. I of course concluded that every thing was all right, removed the cage, and closed the hive. Four or five days ago I went to see how my queen was getting along. I found her, and she is a very nice looking queen, but I was grieved to see that one of her legs was useless. Although she continued laying while I held the comb in my hands, it made me feel very sad to see her dragging her poor shriveled leg over the comb. I can't see why the bees should have stung the queen I prized so highly, when I had the conditions favorable, as I supposed, for her kind reception. The queen still continues laying, though not nearly as fast as the dollar queen. I wonder if the crippled queen will probably live; and if so, if it would probably render her unfit for a breeding queen. I can't answer these questions, as I never had such experience before.

Last year I was very unfortunate in buying queens. I mailed a queen-breeder \$5.00 at different times, \$2.00 of which he said he never received. Of course, I believed him, but I thought he was very unkind, after I wrote and told him I had sent it, when he replied that he thought I was mistaken, as he did not believe it would have been lost or stolen. If I had expressed, or implied doubt, in my statement, I should not have felt wounded. I am well aware that some people will make a positive statement, without possessing a positive knowledge of the subject they are talking about. He referred me to that class of individuals, in a way to include me with them.

WATSON ALLEN.

Bernardsville, N. J., Sept. 21, 1885.

Friend A., there have been frequent reports of queens that, when received and introduced, were found to be crippled in the way you mention, or in a similar way; and sometimes we find queens in our own apiary with one or more of their legs useless. We don't know how this comes about; but as it more frequently happens with queens that have been introduced, I have had an opinion that it was caused by pulling their legs while they were balled, at the time of introducing. The main question is, of course, "Does it damage them?" I have been in the habit of writing to customers when such complaints have been made, to let the queens remain in the hive, and note whether they were as prolific as other queens. In the majority of cases the reports seem to be that

they were just as good, to all appearances. In your case, it would seem as if she were not as good, although it does not necessarily follow, after all, for queens differ greatly in fertility. Still a select tested queen ought to be as prolific as almost any dollar queen, for none are ever sent out as select tested, unless they are good layers.

Now in regard to your last paragraph. I do think it is one of the most unkind things, to make positive statements without positive knowledge, especially where these statements reflect on the honesty of somebody else. A few days ago, in corresponding in regard to some money which had been sent us, but which we never received, the writer said he had sent money by mail thousands of times, and had never lost a copper, and he believed that the money he had sent this time had reached our office, because it seemed to him unreasonable that money should go all right so many times, and then one letter be lost. What absurd logic! The man was a postmaster too. Had he been conversant with his own business he must have known that mail robberies are occurring every now and then. A few weeks ago, quite a quantity of old letters were sent to us by the department. A mail-bag had been robbed, and rifled of every thing that was valuable, and the rest thrown away. The department found these after a time, and took great pains to place them in our hands. It is not only unchristianlike, but I should say that it was extremely ungentlemanly, for any one to say he does not believe a letter was ever sent, from the simple fact that it was never received. People who send out comparatively few letters may not meet with a loss for years; but, does that give them any right to say they do not believe losses occur at all? In our large business, comprising oftentimes several hundreds of letters a day, both going out and coming in, we have an opportunity of knowing how frequently such things do occur; and while I am on the subject, I might mention that the cases where people think they have sent money, but have forgotten to do so, are much more frequent than the actual losses. In fact, this sort of thing occurs so often that we have had postal cards printed like the following, to send out to that class of customers. Of course, the blanks are to be filled for meeting any case in question, and a great many times some portions of the print have to be crossed out, especially the postscript. Here is the blank, such as we put on a postal:

MEDINA, O., 188
MR
YOURS OF is just this minute opened, and both letter and envelope are in my hands. You say you have inclosed but there is positively only
viz:
The envelope was closely sealed, and bears no trace of having been opened. The inside of the envelope contains nothing, and none of its contents have been dropped. In our business we open several hundred letters a day, and it is not a very uncommon thing that the writer has omitted to put in all he intended to inclose. We would like to have you write at once whether or not you can explain the above shortage. Trusting that it was only an omission on your part, we remain Yours Respectfully,
A. I. Root, Per "Ida," Clerk.
P. S.—As you may be in immediate want of the goods, we have concluded to forward them right along, to save you delay.
A. I. ROOT.

You will notice the expression, "Both letter and envelope are in my hands." The

clerk who is intrusted with this very important post always fills out the blanks while she is holding the letter and money in her left hand. This, you will see, precludes the possibility of a mistake. In the majority of cases the writer of the letter replies, on receipt of the above printed postal, that the letter was sent to the postoffice by mistake, before the money was put in, or something of that sort. But sometimes it is impossible to get any trace or clew as to where the money did go. Do you wish to know how often we have occasion to use these printed cards? Well, I should say usually once or twice a week, and during the busy season sometimes as often as two or three times a day are needed. It illustrates the hasty and loose way in which many of the brethren do business. If anybody wants further proof of the carelessness of letter-writers, he should examine the reports from the Dead-Letter Office, which are sent out at the close of each year. Some of the friends have been so unkind as to throw out insinuations regarding the integrity of our clerks. Let me tell you, friends, that all these important positions are filled only by those who have, by long years of faithful work, fully demonstrated their fitness for such positions. Our books and mails and money matters are almost all handled by exceedingly careful, faithful, and intelligent women.

OHIO BEE-KEEPERS ON WINTERING.

FRIEND CLARKE'S COMMENTS ON WHAT WAS SAID AND DONE.

GLEANINGS has made a "new departure" in publishing the proceedings of the Ohio State Bee-keepers' Association, which I have read with much interest, especially the part relating to wintering. Some very suggestive ideas were thrown out on that subject, which I feel moved to discuss a little.

PROPER SIZE OF A WINTER COLONY.

Dr. Besse and Mrs. Culp expressed themselves as averse to very populous colonies at the beginning of winter. I think they are right. Father Langstroth's maxim, "Keep all colonies strong," is a good one for the working season, but I think it is often the case that they are stronger than is necessary or desirable in the fall of the year. A hive, as well as a city, may be overcrowded. I remember, that in the early days of the North-American Beekeepers' Association, when friend Hosmer, of Minnesota, used to be a prominent figure among us (what has become of him?) he astonished us on one occasion by the views he enunciated on this point. He said it is all nonsense to be too humane to kill bees. It is no more cruel to kill old bees than it is to shoot old horses. For his part, he did not want more than about a pint of bees to the hive, when he fixed things up for winter. If a hive were too populous he shook part of the bees on to the ground. It was mostly old bees that fell, and they would die before spring any way. He did not want his hives cluttered up with a lot of dead bees. Wintering bees is like garnering seed-grain for next year's crop; all you need is a good start in the spring. My experience last winter convinced me that colonies of small size will do well, if properly cared for.

Why should bees be permitted to outlive their usefulness? Is it any more barbarous to get rid of old bees than it is to dispatch superfluous drones, or massacre the whole of them when their functions are over for the season? During the working season, bees are incessantly active, and wear themselves out very quickly. It is doubtful whether any that have "borne the heat and burden of the day" survive until the following spring, and I have come to think that only old bees are tempted to take flight in pleasant winter weather. Their instinct teaches them to leave the hive; they enjoy a final flight; like Moses they have their Pisgah, disappear, and "no man knoweth their grave."

THE WINTER CLUSTER.

President Root remarked, that a large colony of bees will contract to the size of a popcorn ball, and winter well. In a back number of GLEANINGS the editor mentioned more in detail a case in which a whole colony was compressed into a ball about the size of an average "Northern Spy" apple, but spread out so as to cover the frames. This is probably the most favorable shape for them to hibernate in. But I do not see how they can take that shape as usually put up for winter. I am fixing my stocks in a way to admit of their making a tight ball of themselves. I am preparing honey-boards on the principle of "Hill's device," using, for the center, sections of cave-troughing cut out of 4 x 4 scantling (see figure).

The gabled part of the honey-board crosses the middle of the frames at right angles. This gives the bees access to all the frames, and they have the warmest, snugest place in the whole hive in which to hug one another when they go off into their winter sleep. There is room for a cluster three inches in diameter; and if they make it in the shape of a "roly-poly" pudding it will hold a lot of bees.

VENTILATION.

Let me shake hands with my old friend A. Benedict, whose tall figure and gray head used to adorn our conventions in "the days of yore." I am glad he is "still to the fore" as a bee-keeper. There is a great deal in his remark, "Bees need more ventilation in winter than in summer." Turn over this idea in your mind for a few minutes. Queer, isn't it, that bees should want more air in winter than in summer? It is not so with human beings. In summer we throw open our doors and windows; but in winter we keep them carefully closed. Bee life assumes two stages. In summer, activity; in winter, repose. In summer, quick wear and tear; in winter, careful hoarding up of the vital forces. Human sleep in winter may illustrate the point. We sleep in much colder apartments than we could occupy through the day. When I was a boy I used to go from a blazing fire and cosy living-room to a cold garret where I could see the stars, and the snow would sometimes drift on to the bed-clothes, but I "slept like a top," as the saying is. I think bees will "sleep like a top" too, if they have a uniform supply of pure still air.

The president responded to Mr. Benedict's remark by saying, "Our practice is to leave the entrance open full width all winter." This had reference, no doubt, to chaff-packed hives. Well, I believe the usual entrances will give bees air enough if they are kept "open full width all winter." But they are liable to become partially or wholly closed.

When this is the case, and the air supply is diminished or cut off, the bees become uncomfortable and uneasy, unlock the cluster, and wander around in search of air. I do not think a horizontal air-shaft so good as a perpendicular one for maintaining a constant change in the air. Nature's mode of purifying the air is by vertical currents that, like an endless chain, move continually. In a bee-hive, with all upward ventilation closed, the air is purified by a downward and upward action that goes on slowly but surely all the time. Is it wise to trust to a horizontal passage which is liable to obstruction or complete stoppage, both from without and within? I think not. "Cyula Linswik" and her sister secure ventilation by daily seeing that these horizontal passages are clear. That is considerable trouble in an apiary of any size. Moreover, scraping the bottom-board every day with a bit of hoop iron disturbs the bees, who do best when kept in absolute quiet. Why not have a perpendicular air-shaft through the bottom-board? My plan of removing the bottom-board and substituting a hopper is perfect, because all dead bees, dry faeces (if they are dry faeces, as I believe), and all debris, fall out of the hive and leave it absolutely clean, while the air-supply is uniform and constant. I do not need to go near my bees from November to April, or to wake them up at any time by a rude scratching on the bottom-board. I believe a two-inch auger-hole through the bottom-board will answer well, but the hive must be raised at least a foot from the ground, or you make a door-way for mice. To tack wire gauze over the auger-hole is to nullify it altogether, because it will soon be stopped with dead bees and the debris that falls from the cluster. I am putting auger-holes in some bottom-boards only by way of experiment, and all my hives are from 18 inches to 2 feet above the ground.

CELLAR WINTERING.

One of the most serious objections to cellar wintering is that, when this is practiced, old bees usually die in the hive. The cellar is dark; and an expiring bee, like an expiring human being, seeks the light,—the former literally, the latter figuratively. Very few bees die inside the hive when wintered out of doors. In the cellar, a lot of dead bees on the bottom-board is likely, if not certain, to cause disease. Another objection to cellar wintering is the difficulty of replacing each hive on its own stand, and I, for one, believe this to be necessary, to prevent confusion. I have no doubt that spring dwindling is partly caused by spring wandering.

SUCCESSFUL WINTERING.

I do not call it successful wintering, merely to secure the survival of a colony. I passed one winter in Manitoba, and managed to survive, but got a rheumatism that has been the plague of my life for two years. I don't consider that I wintered well, though I lived through it. I want my bees to winter so as to come out in spring with clean combs, and brood in all stages, after consuming the minimum if honey. If I can get them to hibernate, they will do this every time. Not that I ever expect to winter bees absolutely without loss. There are circumstances we can not control. I have got one or two stocks I do not expect to winter. For some reason or other the queens stopped breeding early, and even now the stocks are dwindling, with plenty of stores on hand. Every day I notice a few bees coming out and taking their last flight. They fly feebly, make a few circles in the air, then fall to

the ground, crawl about for a little while, and finally give up the ghost. A small percentage of loss must be expected. It is so in all business, and bee-keeping is no exception to the general rule. But a colony that goes into winter quarters in a really normal condition ought to be so managed as to come out all right in spring and will be, when we find out *how to do it*. I think we are on the verge of the discovery, if, indeed, it be not already made. Another spring, I firmly believe, will settle the problem for all time. Wm. F. CLARKE.

Guelph, Ont., Can., Sept. 23, 1885.

SAWS THAT NEED NO FILING.

ANOTHER STEP IN MECHANICAL PROGRESS.

THE single item of filing saws has long been well understood to be an item of no small moment in our mechanical work, and many inventors have studied with a view of making some automatic machine that would take the place of the slow and expensive operation of filing by hand. Not only is the operation slow and expensive, but files are expensive. One trouble that stands in the way is, that no common day laborer could be expected to keep a machine for filing his saw, even if one were invented. Well, the Miller's Falls Co., of 74 Chambers Street, N. Y., have made a start in the business by making tempered saw-blades that are to be used until they are dull, and then thrown away, and a new blade put in. As these blades are never to be touched with a file, they are tempered much harder than any ordinary saw-blade. Below we give cuts of two different saws, arranged to work on this plan.

The first is a meat-saw, such as butchers use. The second is a hack-saw, similar to those we have for some time sold and used for sawing metals. I took one of the hack-saws that were sent me for trial, and gave it to our machinist. I told him the manufacturers guaranteed each saw to cut off a bar of half-inch iron 80 times. He tried it on a piece of inch shafting. It cut it off almost as if it were a hoe or fork handle. After the first cut he came to me saying:

"Mr. Root, how much is this tool worth?"

I told him the price was \$1.25.

He replied at once, "Here is your money. And now I want it understood that this tool is mine."

Do you want to know what the saws cost? The blades only, for the hack-saw, are 5 cts. each, or 50 cents per dozen. If wanted by mail, add 3 cts. per dozen for postage. The blades for the meat-saw are 10 cts. each, or \$1.00 per dozen. If wanted by mail, add 10

cts. per dozen for postage. The meat-saw frame alone is worth \$1.50. It is made of the best quality of polished steel, and heavily nickel-plated. The hack-saw frame alone, made in the same way, is worth 75 cts. The hack-saw frame can be sent by mail for 15 cts. extra; the meat-saw frame is not mailable. The manufacturers also make blades for wood-scroll sawing, at 10 cts. per dozen, the same price as those sold on our ten-cent counter.

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

A. I. ROOT,

EDITOR AND PUBLISHER,

MEDINA, O.

TERMS: \$1.00 PER YEAR, POSTPAID.

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, OCT. 1, 1885.

He knoweth the way that I take: when he hath tried me, I shall come forth as gold. — Job 23: 10.

We have to-day, Sept. 29, 6540 subscribers.

We expect shortly to have a new dress for the front of the juvenile department.

A VISIT TO PETER HENDERSON.

As soon as this present number is winging its way to your homes, I shall, Providence permitting, be on my way to a visit to Peter Henderson, the great market gardener of the world. Notes by the way will be found in our next issue.

HOW LATE CAN WE SHIP QUEENS?

The above question is often asked by somebody who has a good strong colony, found to be queenless late in the season. We expect to ship queens, not only all through this month, but next also, clear into December, unless the weather is unusually severe.

THE ILLUSTRATED BIENZENZEITUNG.

We have before mentioned the excellent quality of the engravings in the above journal, and the issue for September gives us some that it seems to me are ahead of any thing we have seen yet. To cap the climax, a frontispiece contains, not an engraving, but an excellent photograph of Dr. Dzierzon himself.

SELLING BEES IN THE FALL.

If it were not for the wintering troubles, the fall would be an excellent time to buy and sell bees; and where one feels sure he can winter them safely, it is an excellent time to buy bees as it is. See our advertising columns. You will notice that it is a rather poor time to sell, by the extremely low prices at which bees are offered.

PREPARING BEES FOR WINTER.

This matter has been gone over so thoroughly every fall for years past, it hardly seems necessary to repeat it all again. Our text-books give very full instructions, and the matter has been discussed pretty fully almost every month since the disasters of last winter. See that each colony has lots of bees,

plenty of good wholesome food, some sort of protection at the sides, with loose chaff or leaves above the cluster, and a good wide entrance that lets in the air, but excludes mice, and I think you will be all right.

MICROSCOPIC SLIDES OF THE BEE.

We have received from W. M. McAllister, Philadelphia, a full series of microscopic specimens of the bee. They are some of the finest we have ever seen, and comprise a careful selection of all the different parts of the bee, carefully mounted. Besides this, some of the specimens are injected; that is, a red fluid is pumped into some of the delicate tissues, in order that the fine markings and the structure may be more easily seen. Such objects ordinarily sell for from 25 to 50 cts. each; but we can furnish a whole dozen, put up in a neat pasteboard box, for the low price of \$1.50. These slides are $2\frac{3}{4} \times \frac{1}{4}$ inches, and are just the thing for the small microscopes we advertise. Ernest has tested them with his large instrument, and knows they are good.

ARTIFICIAL PASTURAGE.

In localities not too far north, seven-top turnip may now be put in the ground; but unless the plants have time to make a good stout root, the frosts of winter will be likely to heave them out. Raspberry-plants may be set out now; in fact, we have been setting out plants of the Cuthbert for two or three weeks past. Alsike and sweet clover may be sown in the fall, in some localities; but perhaps the safer way will be to put in the seed in the spring. Winter rape can probably be sown about the time of winter wheat, but as yet we know little about it. Can any of our readers give us any information? We tried some a year or two ago, but it was so near like our seven-top turnip that we found it difficult to tell "which from t'other."

MANUFACTURED COMB HONEY.

While riding in a crowded street-car from the College Grounds in Columbus to the Fair Grounds, the conversation started on adulterated honey, and one of the "knowing ones" commenced to tell the old story of how they manufactured the comb out of paraffine and the contents out of glucose, etc. While I was waiting for a good chance to put in a word, Ernest and George Gray took the gentleman up. He was very positive until he found whom he got hold of; but the boys backed him down so quickly that he very soon acknowledged that he did not just know where the honey was made, but that he had heard about it. One of the reasons which he gave for declaring the honey was bogus, was that it was offered at 15 cts. per lb.; but when the boys closed down on him and offered to furnish him 5 lbs. or even less, at only 10 cts. a pound, and 50 lbs. or more at 9 cts., and honey, too, that would stand the test of analysis, quite a number of bystanders put in and wanted to know where we lived, that they might send us some orders. You see, the point is, friends, the world is not half posted. They have all read the sensational items in the papers, and have honestly decided in their own minds that no genuine honey is to be found in the markets, either comb or liquid, and so we bee-keepers have to stand the consequences. Don't let us be disheartened, however. We have the promise, that he that is patient and endureth to the end, shall eventually triumph. Meanwhile it is the duty of every one of us to do all we can to disabuse their minds in this matter.

QUEENS BY RETURN MAIL.

THE COMING BEE.

I believe that, with most all well-experienced beekeepers, it is admitted that, to take any one race of bees in its purity, the Italians are preferable to all others; and yet it is also admitted, that the Cyprians, Holy-Lands, and Carniolans all have good traits not found in the Italians. My efforts have been to combine the good traits of all other new races with the Italians, and yet retain all the good traits of the Italians, and I am happy to say that I have succeeded, even beyond my most sanguine expectation.

HOW I DID IT.

In the first place, the Italians, being the best, I took them as the basis. From a fine imported Italian queen I raised a number of young queens; and before these were ready to become mated I contracted the entrance of all hives except the Holy-Land bees, so as to not permit the drones to fly. Well, as there was quite a number of Holy-Land drones I succeeded in having some of these young queens mated with them. Next I selected two of the queens thus mated (which were very large), and from these two another lot of queens was raised; and by the same method I obtained some very fine queens mated with Cyprian drones, and these are the queens I use to raise from. Now, take notice; as I allow no drones to fly except Italian, and as all bees near me are Italians, all queens raised from these crosses will be mated with Italian drones. Such queens produce fine, large, prolific, and energetic workers.

If you would like to see some live samples of workers, send two letter-stamps and I will mail you a dozen or so.

Will send queens raised from imported stock, if preferred. The Carniolan queens I raise will be pure Carniolans, and mated with Italian drones. All races will be sold at the same price.

	Oct.	Nov.
Single queens, untested, but laying, each,	\$1 00	\$1 00
Six or more, each,	90	90
Single queen, tested	1 50	1 50
Six or more, each,	1 40	1 40

CHAS. KINGSLEY,

19d **Benton, Bossier Co., Louisiana.**

Oldest Bee Paper in America—Established in 1861.

AMERICAN BEE JOURNAL,

16 page Weekly—\$1.00 a year.

Sample Free. **THOMAS G. NEWMAN & SON,**
925 West Madison Street, Chicago, Ill.

FOR SALE,

**A SECOND-HAND TWO-HORSE-POWER
EUREKA ENGINE AND BOILER.**

The above engine has been in use about five years; but Mr. A. F. Stauffer, of Sterling, Ill., of whom we purchased it, writes in regard to it as follows:

I guarantee the engine to be in good working shape, as good as it ever was. I had boiler examined last spring by a steam-fitter, and he pronounced it as good as new. I always used soft water. I am furnishing my shop with new machinery and am anxious to sell or exchange it. I have to get more machinery, and my two-horse power is too light.

Sterling, Ill. A. F. STAUFFER.

We will sell the above engine, to be taken at Sterling, Ill., for an even \$100, and we will put our guarantee on top of that of Friend S. We obtained it of him in exchange for some new machinery, he, of course, putting in a larger engine and boiler.

Also one second-hand **Pony Planer** for sale. This planer is one that we used in our factory for planing all our basswood plank, heavy lumber, etc., and was set aside only because of the increase of our business. The plane is 24 inches in width, and such a machine would cost new \$140 net cash. It is all in good trim, and ready for work, with an extra pair of new knives, and it will be sold for just half price, or \$70.00.

A. I. ROOT, Medina, Ohio.

85 COLONIES OF BEES FOR SALE

Syrio-Italians, Red-Clover Italians, and Hybrids, all on L. frames, mostly wired. Wishing to go south for my health, I offer the above in lots of five or more at \$5.00 per colony, or \$360 for the lot, if taken soon, together with extractor, section cases, extra frames, and fixtures. All requested from the best strains this year.

J. SINGLETON,
19d **34 Public Square, Cleveland, O.**

Wanted. To buy a small farm and apiary. Give terms of sale, honey resources, distance to school and church. California given preference.
E. S. ARWINE,
19d **Patterson, Waller Co., Texas.**

For Sale. Eight Colonies of Bees in 1½-story Simplicity hives; granulated sugar stores, all complete for wintering, at \$8.00 per colony.

JOB LOT OF WIRE CLOTH

AT GREATLY REDUCED PRICES.

SECOND QUALITY WIRE CLOTH AT 1½ CTS. PER SQUARE FT.

SOME OF THE USES TO WHICH THIS WIRE CLOTH CAN BE APPLIED.

This wire cloth is second quality. It will answer nicely for covering bee-hives and windows, to keep out flies; for covering bee-hives and cages for shipping bees, making sieves for sifting seeds, etc.
Number of Square Feet contained in each Roll Respectively.

Inches Wide.	No. of Rolls.	
10	3	rolls of 75, 72 s. f.
12	2	rolls, 100 s. f. each.
20	3	rolls of 166, 1 s. f. each
22	4	rolls of 181, 1 of 160 s. f.
24	6	rolls of 200, 1 of 180, and 1 of 120 s. f.
36	1	roll of 217, 38 of 216, 2 of 195, 1 of 156 1 of 152, 2 of 215, 1 of 210 s. f.
38	16	rolls of 233, and 2 of 234, s. f.
34	7	5 rolls of 281 s. f.
36	37	28 rolls of 316, 3 of 285, 2 of 317, 1 each of 190, 633, 136, and 215 s. f.
42	1	roll of 245 s. f.
44	2	1 roll of 366, 1 of 348 s. f.
46	1	roll of 352 s. f.
48	12	10 rolls of 400, 1 of 100, 1 of 50 s. f.

FIRST QUALITY WIRE CLOTH AT 1½ CTS. PER SQUARE FT.

The following is first quality, and is worth 1½ cts. per square foot. It can be used for any purpose for which wire cloth is ordinarily used; and even at 1½ cts. per sq. ft. it is far below the prices usually charged at hardware and furnishing stores, as you will ascertain by making inquiry. We were able to secure this very low price by buying a quantity of over one thousand dollars' worth.

Inches Wide.	No. of Rolls.	
20	1	roll of 155 s. f.
22	1	roll each of 88, 143, 92 s. f.
24	43	rolls of 200 sq. ft. each; 1 each of 80, 95, 120, 168, 190, 280, 150, 140 sq. ft.
26	38	rolls of 216 sq. ft. each; 1 each of 195, 195, 500, 500, 201, 227, 201, 209 sq. ft.
28	76	rolls of 233, 6 of 224, 3 of 219, 8 of 222, 7 of 224, 2 of 219, 1 of 117 sq. ft.; 1 each of 70, 210, 245, 257, 240, 215, 110 93, 82 sq. ft.
30	36	rolls of 250 sq. ft.; 1 each of 82, 137, 115, 117, 125, 125, 220, 225, 227, 237, 235, 275, 340, 157 sq. ft.
32	14	of 206, 7 of 256, 2 of 253 square ft.; 1 each of 233, 254, 147, sq. ft.
34	31	rolls of 283 sq. ft. each; 1 each of 62, 113, 198 sq. ft.
36	22	rolls of 300 sq. ft. each; 2 of 72, 1 each of 238, 150, 279, 285 sq. ft.
38	1	roll each of 300 and 316 sq. ft.
40	1	roll of 253 square feet.
42	1	roll of 350 square feet.
46	1	roll of 192 square feet.

Box 691, Sherburne, Chen. Co., N. Y.

HONEY COLUMN.

CITY MARKETS.

CINCINNATI.—*Honey.*—There is no material change in the market for honey. Demand is slow for manufacturing purposes, while there is a fair trade in comb and extracted honey for table use. Arrivals are fair. Extracted honey brings 40¢ on arrival, according to quality. Choice comb honey, 14¢ to 16¢ in the jobbing way. *Beeeswar.*—Home demand for beeswax is fair, which brings 20¢ to 22¢ for choice yellow, on arrival. CHAS. F. MUTH, Cincinnati, Ohio.

ST. LOUIS.—*Honey.*—Not much change since our last report. Extracted honey, Southern, in bbls., 14¢ to 15¢. Northern, in kegs, 7¢ to 8¢. In 2-gallon cans, 8¢ to 9¢. Comb honey in good demand (white clover), and wanted at 17¢ to 18¢. A fancy lot would bring a little more. Dark honey, hard to sell.

Beeeswar. Fair demand, 24¢ to 25¢.
Oct. 10, 1885. W. T. ANDERSON & Co., St. Louis, Mo.

CHICAGO.—*Honey.*—Demand good for the best grades of comb honey, and prices firm at 15¢ to 16¢ for extracted. There is not any increased sale, ranging in price from 30¢ to 8¢.

Beeeswar. 24¢ to 25¢. Producers intending to market their comb honey should get it ready and send forward during the mild weather, as it bears transportation much better than when it is freezing weather. Oct. 10, 1885. R. A. BURNETT, 161 So. Water St., Chicago, Ill.

CLEVELAND.—*Honey.*—Honey has been in better demand lately, and new honey has moved off quite satisfactorily at 14¢ to 15¢ for best 1-lb. sections. Old honey has also taken a little start at 10¢ to 13¢. For extracted, there seems to be no inquiry. *Beeeswar.* 22¢ to 25¢. A. C. KENDEL, 115 Ontario St., Cleveland, O.

MILWAUKEE.—*Honey.*—The receipts of comb are beginning to arrive more, yet the supply is not large, demand moderate. Prices for best 1-lb. sections, 16¢ to 18¢. Extracted, good demand, 8¢. Oct. 10, 1885. A. V. BISHOP, 112 W. Water St., Milwaukee, Wis.

FOR SALE.—5000 lbs. extracted clover and basswood honey in 10-gallon kegs at 7¢ per lb. Kegs thrown in free of charge.

M. ISBELL, Norwich, N. Y.

EXCHANGE DEPARTMENT.

WANTED.—In exchange for new varieties of strawberries and raspberries. Plymouth Rocks, Light Brahmas, Pekin Ducks, new varieties of potatoes, and small-fruit plants, cherry and quince trees. P. SUTTON, Exeter, Luz. Co., Pa. 16-23rd

WANTED.—To exchange bees for small planer for wood, also one for iron. 18-19-20d HENRY PALMER, Hart, Mich.

WANTED.—To exchange for bees, 10,000 Mammoth-Cluster Raspberry-plants; \$1.00 per 100; \$6.00 per 1000; also 20,000 Strawberry-plants, Crescent Seedling, Cumberland Triumph, Sharpless, and Glendale; 75¢ per 100; \$4.00 per 1000. 18d W. J. HESSER, Plattsmouth, Neb.

WANTED.—To exchange one-half bushel of extra fine white clover seed for alsike clover seed. 19d to 20d M. A. GILL, Viola, Rich'd Co., Wis.

WANTED.—To exchange bees for registered Poland China Pigs. W. Z. HUTCHINSON, 20d to 21d Rogersville, Genesee Co., Mich.

FOR SALE.

50 COLONIES OF BEES in Langstroth and Simplicity hives—hybrids in good shape for winter; \$3.50 per colony on the cars, or \$3.25 as they stand. 20-21d GEO. W. SIMMONS, Newark, Del.

DADANT'S FOUNDATION FACTORY. Wholesale and retail. See advertisement in another column. 3b to 4d

Black and Hybrid Queens for Sale.

Hybrid queens, 50 cts. each; black queens, 25 cts. each; from Aug. 1st to Oct. 1st, safe arrival guaranteed. G. K. RAUBENBUSH, Reading, Berks Co., Pa.

To those in need of queens, I offer about 50 fine young and prolific hybrid queens at 40 cents each, safe arrival guaranteed.

T. F. KLOER, Terre Haute, Vigo Co., Ind.

I have now three hybrid queens for sale at 40 cts. each. Guarantee safe arrival. J. H. JOHNSON, Middaghs, Northamp. Co., Pa.

OUR OWN APIARY.

HOW TO DESTROY WEEDS AT THE ENTRANCE, BY
 THE APPLICATION OF SALT.

ANY apiarist who is at all neat and tidy about his apiary, knows what an eyesore it is to have weeds and grasses growing at the entrance of his hives, and that, too, during the height of the honey-flow, when time is precious. To take a long knife or other implement, and cut away or pull up the weeds, is not only expensive but exceedingly disagreeable. Well do I remember when it was my allotted task as a juvenile apiarist (?) to hoe away those "pesky weeds," and how those bees, "peskier" still, *would* contrive, despite my frantic efforts, to plant a sting above my shoe-top, or, worse, remind me of their presence up my trousers leg. I was young and inexperienced, and had a kind of mortal terror of the bee. To tell the truth, I am not particularly fond of meddling with the entrance of hives now. One vacation, just prior to returning to school, I placed a little salt at the entrance of two or three hives, by way of experiment; but as I soon returned to school I never knew how it resulted. Our apiarist, however, during this year and the preceding, has made it a complete success, and at a very insignificant cost. About ten days ago it took him about an hour to sprinkle salt at the entrance of 220 hives. When common barn salt is worth \$1.25 per bbl., the whole expense per entrance, annually, including time, is less than a quarter of a cent. Two days after the application of the salt you might see the weeds killed, root and all, at every entrance. Even the hardy dandelion shared the common fate. The

action of the salt works best, and is almost immediate, after a rain. Where our entrances were, a day or so ago, a little obstructed, they are now perfectly clean and I fancy the bees appreciate the change too. Now is a good time, when work in the apiary is not pressing, to kill off the weeds; and during almost the whole of the next season you will find little trouble from the weeds at the entrance. It seems to me a good deal of importance needs to be attached to this. It is expensive business, and not a little loss of the much-sought honey-crop, to have the little fellows wasting their time by bumping their heads against the weeds, and then to crawl over what is to them mountains of obstructions.

BEES FLYING OUT ON CHILLY DAYS.

Oct. 7.—It has been cold and rainy for the last two days. Yesterday, while the sun was out for a short time, a good number of bees filled the air. The sun soon disappeared, and the atmosphere became chilly as before. Then you might have seen little clumps of bees huddling together on the hive-covers and in the grass, too much chilled to return home. There must have been two or three pounds of bees at least that were lost by the sudden change of temperature. A short warm spell on a wet chilly day seems not very profitable to the apiarist.

MORE ABOUT THOSE CARNIOLANS.

This morning, Oct. 9, was cool and frosty, and I accordingly concluded it would be a good time to test more thoroughly the disposition of that Carniolan swarm. Proceeding thence without any smoker we opened the hive, but the few remaining Italians stuck up their "tails" as usual in a threatening attitude. The Carniolans acted quite differ-

ently, and seemed to be entirely unaware of our presence—in fact, like Italians on a warm day. We pointed our fingers at their “noses,” in a manner calculated to aggravate most bees. The new bees could not be induced to fly up; but the few Italians seemed inclined to resent, and darted with dire intent at the finger-point. Our apiarist then shook a frame of the bees before the entrance of the hive. They fall off quite readily, but I think not as easily as the black bees. I then shook a frame with similar results. A more extended trial next season will prove this matter more definitely. If all Carniolans are like ours in this respect it will afford another at least partial means of distinction between them and the blacks.

Now, by way of caution I would suggest that we bee-keepers be a little careful about investing in these bees too largely at first. If one or more swarms prove valuable for you during the coming years you can then invest. But, remember that the Italians have already stood a most severe test for years.

A FRAME OF BROOD AND ONE-FOURTH POUND OF BEES.

Aug. 1st, our apiarist took a quarter of a pound of bees, a queen, and a frame of brood, to see what he could do with them. Up to date (Oct. 10), without any outside assistance, it is a good strong swarm, and a very little feeding will put them in fine condition for winter. Our readers will see what can be done with weak swarms, even though rather late in the season to build up.

PUTTING THE BEES INTO WINTER QUARTERS.

Our apiary is now reduced from 330 colonies to 200 by doubling up. We shall not have to feed a pound of sugar syrup this year for the reason that, during the honey-flow, we left about a dozen of our strongest colonies to gather honey. Our object was to secure nice straight combs of sealed honey. Every colony now has from five to six of these combs in the apiary. Where such combs were not entirely finished they were filled out by placing partially filled combs in the upper story, as I told you in the last issue. You will remember, that last year our bees had almost entirely sugar-syrup stores. If our bees should die very largely during the coming winter, we might attribute the loss to the honey. However, I do not think we need to be alarmed, as the honey is well cured, and is, I fancy, what Bro. Heddon would call “well-ripened honey.”

ERNEST R. ROOT.

MORE FACTS ABOUT CARNIOLANS.

THEIR DISPOSITION AND COLOR.

AS usual, GLEANINGS came to hand promptly; and here let me say, this is the beauty of a bee-paper. This is one of the reasons I like GLEANINGS. I know just when to look for it. While scanning its contents I was much interested in Ernest's description of the Carniolan bees; and as he invites reports from others, I take the liberty of telling what little I know of them.

I find the Carniolans, when strictly pure, to all have that steel-blue color that has been spoken of, and that they resemble the blacks but very little more than the Italians do. The white-gray rings Ernest speaks of are very prominent, and will show themselves at once when crossed with other races. In form, it is true, they resemble the Italians; but I feel sure that Ernest will change his

mind in regard to their disposition when he handles them more; for I find no need of smoke at all in handling them. They remain on the combs quiet, although they can be shaken off as easily as any other race of bees I have ever seen, and, as has been said, at once cut for the hive, instead of taking wing. It is true, that when you are handling them they seem to take no notice of even robbers that may be flying around the comb; but let a robber attempt to alight at the entrance, and he is handled as roughly as he well could be. I find the Carniolans to be equal to the Cyprians for protecting their hives, and as good workers as I have ever seen, as far as I have tested them.

One other peculiar point is to be credited to the Carniolans, which is, they gather no propolis at all. All cracks are filled with wax instead of propolis; consequently the frames are free from that sticky substance gathered so largely by other bees; and then, the sections are so much nicer to handle. Besides, their combs are as white as the driven snow. As far as beauty is concerned, that depends altogether on different people's notions of color. What suits me best is, the bees that will give me the largest amount of nicest-looking comb honey with the fewest stings.

Now, I have not fully tested the honey matter to my entire satisfaction, but I have the matter of stings, and am fully satisfied that they are less inclined to sting than any other race of bees I have ever seen. When I have had another season's experience with them I will report further. I hope others will give their experience with these bees.

JAMES B. MASON.

Mechanic Falls, Me., Oct. 5, 1885.

Here is Ernest's reply to the above:

Why, bless your heart, Bro. M., I am of the same opinion still. Did you not misinterpret me in regard to the disposition of the bees, on page 658? If you will look again, you will see that I say, “As has been said, the Carniolans seem very gentle.” Also notice what is said of them in this issue in the department of Our Own Apiary. We are glad of the additional facts in regard to propolis.

HONEY LATE IN THE SEASON.

A GOOD REPORT FROM MRS. HARRISON.

LAST week I prepared some feed for our bees, *a la* Heddon, and on arranging a hive for the purpose I had occasion to lift the front of it, when I discovered it to be very weighty. The long-continued rain of the preceding week had promoted abundant bloom, followed by warm balmy weather, and honey was coming in at a rate unequalled this season, and lasted seven days. There has been no frost in this locality, but the nights are now cool.

In a letter dated Sept. 18, Mrs. Axtell, of Mercer Co., Ill., says “We are having a wonderful honey-flow just now. Before that, our bees had been living on the honey gathered two months before, not getting enough to live on from day to day. We began to think we should have to feed largely to winter on; but we are very thankful not to have to feed, as it is a big trouble, we think. Our hives are getting so full of honey now we may have swarms any day; not much surplus, however.”

Yesterday I transferred and united some small

after-swarms for a lady friend, that had been put into nail-kegs. The comb was almost all full of brood. These casts were too small to winter; and as she had a large black colony the queen from it was removed, and one from the small colonies substituted, as it was a good Italian. I never handled bees before at this time of the year, when they were so docile.

Goldenrod and asters are rather late blooming, but very abundant. MRS. L. HARRISON.
Peoria, Ill.

THE REASON WHY THE COMBS MELTED DOWN.

A LITTLE STORY WITH A MORAL TO IT.

EDITOR GLEANINGS:—Yesterday, after I had put the grape-butter to cook, and the tomato preserves to stew; had poured water on the lye-hopper, and put a tub under it to catch the drips; had superintended the digging of the holes for the posts that my wire clothes-line (price 35 cts. for 100 feet, sold by A. I. Root, Medina, Ohio) will be nailed to; after I had set Jessie to shelling the Lima beans, and Minnie to making Dutch pies; had told Mr. Chaddock to use the spool of wire (annealed and shellacked so that it will not soil the fingers, sold by A. I. Root, Medina, Ohio, for 10 cts.), to hang up his seed-corn on, instead of poles; when I had given the brass kettle to a little boy whose mamma wanted to make apple-butter in it; had put Sarah to blacking the kitchen stove (using "Dixon's best" bought of A. I. Root, Medina, Ohio, for 5 cts. a package); had hung Harry's hat on the new "hat-rack" (folding, all black-walnut, price 5 cts., bought of A. I. Root, Medina, Ohio); had tied up his finger, cut with his new "boy's knife" (sold by A. I. Root, for 5 cts.), and had cut him a slice of bread with my new bread-knife (bought of A. I. Root, Medina, Ohio, for 10 cts.), and spread it with butter to dry his tears; in fact, when I had oiled the whole household machinery, and set it to running smoothly, so that no one need call "Mamma, mamma," for five minutes, I thought I would begin to get my bees ready for winter. The first hive I went to was a dry-goods box fixed to hold Gallup frames, that I had put one of those 1-pound packages of German brown bees in. The box is as long as two Gallup hives; and as there were only six frames of brood in it I thought they would be cool enough without any top box on; and as none of the top boxes fitted, I did not put any on. Well, what do you think? Four of the six frames of comb had melted down and were lying in a crumpled mass in the bottom of the hive, and the bees had built new comb in the frames, about half way down.

Then I remembered that last week in July, when it was so hot that people forsook their beds and wandered around in the yards at night, seeking coolness and finding it not. I knew that those bees had come out and stayed out for days; but as all the other bees were out taking the air at the same time, I thought it was all right. When I saw the fix they were in, my heart rose up in my throat; for I thought if these few bees in this long box have melted combs, how will it be with those colonies that are running over with bees? I examined them and found them all right—not a single comb down; they all had two honey-boxes on; most of them had one full and one empty. Top stories

make a shade; spread-out dry-goods boxes do not. See how wise I am, after the thing is done!

MAHALA B. CHADDOCK.

Vermont, Ill., Oct. 3, 1885.

Why, my good friend, I supposed everybody knew that it would not answer at all to let the sun shine right on top of a hive when the bees in the combs were close up against said top. In the Simplicity hive we have a shallow chamber under the cover, and then have the cover painted white so it will not absorb the heat; but even with this arrangement the hive sometimes gets very hot during extremely warm weather. An upper story is better, as you say; and the chaff hive, with its permanent upper story and chaff-packed walls, is still better for hot weather, as well as for cold weather.—We are very much obliged indeed for your kind mention of the way in which our household conveniences help things along in the economy of your family duties. It seems to me, that, when that boy cut his finger, a piece of court-plaster from our three-cent counter would have been the quickest way to have fixed him up.

PREPARING FOR WINTER.

THE WAY FRIEND HEDDON ADVISES.

IN reply to inquiries sent by yourself and others, I will endeavor to briefly outline my ideas regarding wintering bees in eight-frame L. hives, or my own style of hive, as that is what is called for. I must say, that for those residing north of latitude 38 or 39, I consider indoor wintering best, safety and inexpensiveness considered. South of this I think I should prefer to have my colonies packed, and left on their summer stands. I am aware, that during our most moderate winters, that line should be moved northward; but I think it is wise for us to prepare for the worst, in every case. When so prepared we enjoy a feeling of safety that is a great comfort. I feel confident that I can winter any or every colony of my bees, with certainty, *every time*. The knowledge I lack, and so much desire, is to know if *all* of my precautions are necessary.

HOW TO PREPARE FOR CERTAINTY.

About the last of Sept. to the 15th of Oct. (according to latitude and season), remove all combs from your bees, and replace others free from all honey and bee-bread. Feed the bees properly with prepared sugar syrup till the combs are well supplied (I give them five combs, filling the space of the other three with two fillers, or dummy frames). Now, if you will place such a prepared colony in a repository where the temperature will never go below 45° nor above 50° F., it will be less liable to die in winter than will your cow or horse. You need take no notice of the humidity of the repository (a cellar preferred), nor of the ventilation, if your cellar is large in proportion to the number of colonies you place therein. Give no upper ventilation to the hives, but plenty at the bottom. Your bees will soon enter that quiescent state in which, according to Langstroth and Cook, they require but just the least bit of air.

The above is what I feel quite positive of. I think, that where that temperature is kept, that, should your combs contain bee-bread, it will do no harm, as it will not be touched. It is also true, that most

of the time our hives contain honey of such character that, after the bees have subsisted upon it for five or six months in that temperature, they will come out in spring in very unsatisfactory condition. However, I think that this is not always the case in all localities; but I think, as a rule, that if we so work our colonies during summer and autumn, that at the close of the harvest the hives contain but little natural stores, and then feed syrup on top of that, then if we carefully maintain the specified temperature, we are quite certain of success. I believe this, and shall give it careful and comprehensive tests during the coming winter. I hope to adopt that system in the future.

When we adopt the outdoor-packing system, we take more or less chances regarding temperature. I have practiced the following plan of protection, and it answers well during our open or moderate winters; but during the one just past it proved to be inadequate for this latitude.

First prepare your hives and combs to suit you; then adjust one of our cases or supers on the hive (with cloth between), and filled with any good non-conducting material, with the hive-cover on the case or super.

HEDDON'S ARRANGEMENT FOR OUTDOOR WINTERING.

By referring to the above cut I will now describe our simple and cheap method of packing. A shows the end of the permanent bottom-board of the hive; F, the stand the hive sits on; D, the case as filled, as above described; H, our summer shade-board; I, the winter bridge, composed of four pieces, 1 piece $11\frac{1}{2}$ inches long (the inside width of the hive), by $3\times\frac{5}{8}$ %, and the others $11\frac{1}{4}\times4\times\frac{5}{8}$ %, and the side-pieces each $\frac{1}{2}\times\frac{5}{8}\times9$. Now let us proceed to push this bridge into its position, the points into the entrance, the piece marked I, outside for an alighting-board, and the other piece, forming the bridge, to keep the packing out of the bees' passage-way. G is a rim made out of rough lumber, being 6, 8, or 10 inches larger, inside measure, than the hive is outside measure, thus giving 3, 4, or 5 inches of space on all sides, to fill with packing, sawdust preferred by me, and sawdust fresh from green logs does well, and soon dries out. You will see by the engraving that the sides and back end are wider than the front, and they may be enough wider to come down to the ground, or no further than shown in the engraving, as may be preferred. The hive being ten inches deep, the front end of our rim is represented as being about 12 inches, and the sides and back pieces

about sixteen inches wide; any old "cull" lumber will do for this rim. When we use them as shown in the engraving, we fill in the dust till it banks up, on the ground, and thus stops running down, and soon fills up. We press it snugly, and fill up to the top of the rim, and the dotted line shown about two-thirds of the way up the case, this line being about two inches higher than the top of the rim. In a windy situation I would advise having the rim made wide enough to come to the ground at sides and back end; here we do not need it, as we have but little wind within our eight-foot board fence, and sawdust is plentiful. Straw, chaff, or leaves, or almost any thing, can be used to pack with. Now adjust the shade-board H, as shown in the engraving, to keep the snow and rain from the packing. This board is 2×3 feet, and any moisture that drives into the top of the sawdust will dry out before it gets one inch deep; no dampness will arise two inches above the ground. I place a 15-lb. stone on the board to hold it in position.

Now, if this rim came down to the ground, and were high enough to come up to the shade-board H, and no upper case or packing were used, the hive-cover resting tightly on the hive, allowing no upward ventilation or absorption, you would have your colonies protected in the same manner as were Drs. Southard's and Ranney's 125 colonies at Kalamazoo, Mich., during the past winter, and their success was perfect. I am becoming of the opinion, that our upper absorbents are usually useless, and oftentimes worse.

The two experienced honey-producers just referred to believe this and work accordingly, and their success testifies in favor of their claims. There is much more that might well be said, but this article is long enough. I might simply add, that I can not tolerate heavy cumbersome hives for summer.

Dowagiac, Mich., Oct. 5, 1885. JAMES HEDDON.

Friend H., I feel pretty sure that bees will winter all right, prepared as you direct above, but I should be a little backward about being *so very positive*, as you seem to be. I do not know that there is any thing in the arrangement that I should object to, except the untidiness of such outside shells, made of rough cull boards. The ventilation you secure by making the case G not up to the top, is, I believe, an excellent idea, and your large shade-board H is also a good thing, without doubt; the same with your 15-lb. stone, only I am afraid I could not tolerate the looks of the thing, as I have said before. If there is any thing I do dislike to see in passing somebody's home, it is barrels sitting around the yard, with ashes or something else in them, a great awkward board on the top, and then a big stone to keep the wind from blowing it off. May be it is one of my notions, but it always makes me homesick, and I want to look t'other way, to find some pleasanter subject for contemplation. I like to see substantial, permanent structures, and then have them painted. No doubt it is only a notion of mine, but still I do like a chaff hive just on that account. But I suppose these same chaff hives are just what your concluding sentence is drifting at. One thing more, and I close: If I am correct, you would do your feeding between October 1st and 15th. It seems to me that I should prefer to do it a

little earlier, although we had excellent success in feeding even later than the last date mentioned. In our locality, 30 miles south of Cleveland, I prefer to take the chances of outdoor wintering.

NOTES ON GLEANINGS FOR OCT. 1ST.

HONEY FROM MAPLE.

OUR friend Doolittle always writes of something interesting to the practical bee-keeper, and usually we all feel like saying amen to his wise conclusions; but his conclusions as to the bee-products of our maples will not answer for all localities. I have known in one or two cases, when the weather was very favorable, when the bees secured a large amount of nectar from these grand old trees. I remember once of saying to our good friend Benton, that I believed that, were our colonies strong, and were not our spring days so capricious, our maples would be among our best honey-plants. It is very common that bees can gather pollen when the weather forbids nectar secretion. Very likely some plants are more susceptible to cold than are others. I think this is true. I do not know how the maple ranks in the list. I only know that, here in Central Michigan, the maples do furnish anon rich supplies of nectar, and that, too, of a very pleasant and beautiful kind.

RIPE HONEY.

Now, Mr. Editor, I am much interested in this matter of "ripe honey." May I send you some clover and basswood honey for comparison with that of our friend Heddon's? Ours was extracted when very thin; and if it is not equal to Mr. Heddon's, or any other, then I wish some of theirs at once. Again, we have over 200 students here, and about 300 in all in our college community. I have often extracted quite thin honey which I thought was peculiarly pleasant, and have supplied this entire community with it, and I have yet to hear the first murmur that it was unwholesome, or more likely to cause colic.

VARIATION IN THE TIME OF HATCHING BEES AND OTHER INSECTS.

Of course, we all delight to hear from our dear and revered friend Mr. Langstroth, I have often tried such experiments as he details, and often we can get drones in 24 days. Sometimes it takes 26 or 27. This is no surprise to an entomologist. We find this variation in time of development in all insects. Indeed, in our breeding insects we can vary it at pleasure, by withholding food or subjecting to cold. Eggs that will usually hatch in days may be kept for months or years by putting them in a cool place. In like manner, development in both the larva or pupa state may be retarded. From this we note that we can not give hard, fixed figures in such matters. Variation of temperature, variation in number of bees, variation of care by the bees in protecting brood from the cold, each or all may vary our figures. So the queen, the workers, and the drones, may be retarded hours or days. Still, Bevan's figures as to queen, workers, and drones, have all been verified by my own observations as correct, under the most favorable conditions.

I believe friend Hart is correct in what he says about yellow jessamine. I bargain to eat from it freely, if any one will send it to me.

We are all very sorry that Mrs. Harrison must ev-

er needs be "laid aside for repairs." Mr. Editor, if said lady is as good a bee-keeper as she is writer, she is argument enough as to the ability of ladies to become first-class apiarists.

GELESEMUM HONEY.

I read Dr. Higbie's article on gelesmium honey with great pleasure and satisfaction. I indorse every word of it. It is not the plant, I ween, but the person, and the amount eaten. One year, in the early days of this college, the students, in felling trees to clear up a place for our farm operations, were so (un)fortunate as to cut a bee-tree. You know, Mr. Editor, our students all labor three hours daily at manual work; and as the college was located in a dense forest, of course the first work was to clear away the forests. This bee-tree was cut in the forenoon; and it goes without saying, that hearty, vigorous young men needed no urging to take their fill of the delicious nectar; and when is honey ever so good as under just such circumstances? In sooth, no one could ever explain where so much honey went to. But the sad sequel—few of those students went to class that afternoon. True, none died; but many thought they were going to. It was not poisonous honey; it was not bee-stings. It was the undue eating—*overeating*—of pure rich honey. The stomachs couldn't manage such a load, and cried out, and many of the possessors of those stomachs fairly shrieked with pain. I have no doubt but that the same explanation would account for the terrible sickness of those ancient soldiers, as well as for the soldiers spoken of by Dr. Higbie.

The last part of the doctor's article I do not believe to be correct. In fact, Mr. Editor, a little thought refutes it. "Wild bees" are only tame bees in the forest. They are no whit different except in their place. If they sting honey, all our bees do. But, do they? Again, honey-comb, if stung, would not pull out the stings. Thus I think any stings seen in such cases came from crushed bees. Every bee-keeper often takes honey from bees under precisely the same circumstances that honey is taken from bees in the forest, and it is not unwholesome I have seen and eaten much of such honey, and I have never seen any such phenomenon as that suggested by Dr. Higbie.

VALUE OF ALSIKE AS A HONEY-PLANT.

Mr. Editor, I believe our farmer-apiarists do not appreciate the value of alsike clover as a honey-plant. Last June we had much white clover, but no alsike about the college. Our bees were strong, but we got very little honey. I visited my brother one day and was much surprised at the great amount of honey he had taken. I said, "I don't see into this. Our bees are as strong as yours; the distance is only twenty-eight miles, and the conditions as to temperature and rains are very similar." He said, "Come with me," and we passed to a large field of alsike clover. It was fairly loud with bees. He said, "Here is the solution. The bees have been working like this for days." Hurrah for alsike!

A. J. Cook.

Agricultural College, Mich.

By all means, send us some of the honey, friend Cook, and we shall be quite willing to own up, if need be. My objection to un-ripened honey is not that it is unpalatable when first gathered, but that it gets bad after being kept. Perhaps if exposed to the air, so as to allow the surplus water to evap-

rate, this would not be the case. Our troubles have been, that it would sour when put into bottles immediately after extracting.—I agree with you in regard to alsike. It seems to me that here is a field for bee-men who are farmers; at least, so far as my experience goes, a field of alsike is a pretty safe investment.

THE PICTURE OF FRIEND HILTON'S APIARY IN OUR LAST ISSUE.

HE TELLS US MORE ABOUT IT.

GLEANINGS is here, and the cut of apiary is nice. You say my letter is altogether too short. I didn't know it would be published when I wrote it. Yes, the square building in the center of apiary is my honey-house and extracting-room. The queer-looking arrangement in my hand is for taking down swarms, and is made of an oak half-bushel basket, with handle removed, and a pole fastened to the bottom. It is light and strong. The shop in the rear is where we put together and paint our hives; but the stuff is gotten out at the mill just under the hill, in the background of the picture. The 100 hives you speak of were ordered by W. D. French, then living at Columbus, Ohio, but later he ordered them sent to near Grand Rapids, where he now has a fine apiary and trout-pond. The lumber that made those hives was delivered at the mill for \$4.50 per 1000, and paid for in honey, although there is not a pine-tree in sight of our place. Those you see in the distance are hemlock.

Many thanks for kind words, and especially your closing remark. **UNCLE GEORGE & Co.,**
Fremont, Mich., Oct. 5, 1885.

HUMBUGS AND SWINDLES

PERTAINING TO BEE CULTURE.

THE BOHEMIAN-OATS SWINDLE, AGAIN.

ABOUT one year ago, I think, I saw in GLEANINGS a reference to an oat swindle that had been perpetrated on the farmers in your vicinity by the Bohemian hullless oat. Parties are now in this vicinity, securing many orders for them at \$10.00 per bushel. If there are any of this kind of oats for sale in your neighborhood, please inform me at what price they can be bought, or at what price you can ship me a bushel or two.

D. E. BEACH.

Mina, Chaut. Co., N. Y., Oct. 1, 1885.

Friend B., the oats can be purchased in any quantity for from 75 cts. to \$1.00 per bushel. Any reliable seedsman can furnish them, or they can be had in Cleveland and various places. Ferdinand Schumacher, of Akron, O., the largest manufacturer of oatmeal, perhaps, in the world, recently stated in the *Ohio Farmer* that he did not want them at any price. They are not suitable for making oatmeal, and are not desirable for any purpose. The swindle is one of the most shameful frauds that have ever cursed our rural population. No further proof is needed that it is a fraud, than to hear the

men who sell them say they don't care if the oats are sold at a dollar a bushel, or less, and then go right on selling them at \$10.00 per bushel, on the plan that has been so many times written up and explained.

Since the above was written, we have received the following from friend Kendel, of the Cleveland Seed-Store:

We have no Bohemian, or "hullless" oats in stock. They are unworthy of cultivation. Horses do not like them; for oatmeal they are of less value than common oats, and we have not heard of any point they excel, except in gulling credulous farmers. We sometimes have them offered, and think we could get them for about 50 cts. per bushel, but should want to be assured that they were intended for legitimate uses only, as in your case. If we have any offered soon, we will write you.

A. C. KENDEL, Seedsman.

Cleveland, Ohio, Oct. 6, 1885.

DOUBLE-POINTED TACKS MADE OF STEEL WIRE.

A VALUABLE ACQUISITION, USEFUL TO BEE-KEEPERS AND PEOPLE IN GENERAL.

OUR friends may remember that double-pointed tacks have been talked about some little time. We have succeeded in getting them at a pretty low rate by the pound, so they really do not

cost much more than common tacks by weight. Below we give you cuts of six different sizes and patterns, the cut showing the full size of the tack. Both larger and smaller sizes are made than those shown; but at present we have in stock only the two middle sizes. Price 5 cts. for a package of two ounces; 18 cts. for a half-pound package; 30 cts. for a full pound; \$2.75 for 10 lbs., or \$25.00 for 100 lbs. If wanted by mail, add 18 cts. per lb. for postage and packing.

These tacks are being used extensively for putting down carpets. The carpet can never get away, the head of the tack can not pull off, and at the same time they are easier to draw out than the common tacks. They are also very useful for many kinds of woodwork. The wood can not very well split, because the two points inclose a piece of wood; and although they are made of flattened steel wire, the temper is such that they can be clinched so as to be wonderfully strong and secure. The points are made by cutting the flattened wire at an angle, so as to leave a keen tapering steel point that will go straight into any thing, even zinc or tin. Very small sizes are quite useful for repairing baskets, and are much stronger than any ordinary tack.

SEEMINGLY ANOTHER PHASE OF THE DISEASE FOUL BROOD.

HOW TO CURE BY THE INTRODUCTION OF A NEW QUEEN.

I WROTE you over two years ago (see GLEANINGS, page 276, 1883), in regard to a brood disease that was prevailing in this vicinity; and as I have received inquiries lately in regard to whether I have found any remedy for it, I shall be pleased if you will allow me to reply in GLEANINGS, hoping thereby to benefit others as well as those who have inquired. The following is a copy of a card that I received a few days ago:

I noticed your article in May No. of GLEANINGS, 1883, on foul brood. I have found it in my apiary, the same kind that you speak of; others have it in this vicinity. Have you found any remedy? If so, you will much oblige by writing to me.

S. H. WETMORE.

Wellsboro, Tioga Co., Pa., Aug. 28, 1885.

Since the publication of the above-mentioned article I have given the matter a good deal of attention, and on some points of the trouble have arrived at the following conclusions:

1. That the disease is not contagious by contact, or by introduction of bees, honey, comb, brood, etc., from an affected colony into a healthy one.

2. That the infection is transmitted by the fertilization of the queen by a drone from a diseased hive. Although I am not positive the infection is conveyed in the manner mentioned, I have what I think very strong evidence in that direction. But allowing the foregoing to be correct, I am not yet able to say why so large a proportion should be affected. I now understand its management so well that it no longer has any terrors for me. I have cured every case that has occurred among my bees in the last two years. All that I have found necessary is to remove the diseased queen and introduce one that is healthy and fertile, with sufficient amount of fresh bees to clean up the premises. I have generally succeeded in the following way:

Remove the diseased queen, and allow the hive to stand eight days, then open and cut out all queen-cells started, and introduce a frame of honey, brood, and adhering bees, from a healthy colony from which to raise a queen. Cases managed in the ways mentioned have mostly banished every trace of the disease in about two months. It seems to be important to supply the diseased colony with a fresh force of workers to do the house-cleaning. In one case where I introduced a queen and the few attendant workers received by mail, it took nearly two years to overcome the trouble, and required considerable feeding to keep them from starving, till they got well. But they eventually got through all right.

Last season I thought the Italians were not subject to the trouble; but this summer I have found two colonies, apparently pure Italians, among my 75 that have received the "offensive taint."

I am glad that I am able to assure bee-keepers that there is no danger of spreading the infection by contact with the diseased matter, as I have frequently taken frames from diseased colonies and put them into healthy ones, without transmitting it. I have owned and kept bees continually for 38 years, and have used the Langstroth frame since 1858. As we have no basswood, and but little buckwheat or fall flowers, I have never been able to get very large yields of honey. Nearly all our surplus is from the white clover; and as it was nearly all

winter-killed we have got only about 1000 lbs. of dark stuff from the poplar and other timber-trees. I think it is about four years since I first noticed the disease among my bees, but I am pretty well satisfied now that they had it for more than twenty, as I never extracted, and seldom opened the hives, as they did not yield me much profit. I will add, that the disease doesn't seem as virulent among the Italians as among the common blacks. I think very likely it is mistaken by some for true foul brood. It seems to be a venereal disease of the honey-bee; but call it what we may, it has done immense injury to the bee-business over a large scope of country.

MILTON HEWITT.

Perryopolis, Pa.

Friend H., the information you furnish is quite important; and since you mention it, I am inclined to think the greater part of the diseases that affect bees can be cured or prevented by the introduction of a new queen, in the way you allude to; for introducing a new queen is virtually making the old colony a new colony. If we could cure a sick horse by putting another one in his place, without very much expense, what a wonderful thing it would be! and with bees we can do this with comparatively little or no loss. The nameless bee-disease that has been so much talked about, I am quite certain would yield to just such treatment. In fact, this plan must cure any disease, *not a contagious* disease, for it is virtually removing every thing but the combs and contents.

MRS. CHADDOCK ON THE SORGHUM BUSINESS.

HOW TO DISPOSE OF THE SYRUP AFTER YOU HAVE GOT IT.

NO, I do not mean that people must not carry on business, or neglect business in order that they shall not worry. I like to work, to buy and sell, to make bargains, and to live up to them. I am very sure that if I had been a man I should have been a merchant, or "a big cattle-man." I like the excitement of trade, the hurry and the bustle; but I am not going to worry. Every year we raise sorghum, Mr. Chaddock does not think it pays to raise sorghum; he says it is cheaper to buy it. I know that it *does* pay to raise it. So we children raise it, strip off the blades, cut off the tops, cut it down, load it into the wagon, drive to Aunt Jane's, and unload it there. We like to do it. Two of us go with the load, and two stay at home and cut up another load. Every year Aunt Jane told us we could either pay 25 cents a gallon for having it made up, or else give her half the molasses; and as we never have any money we always gave half. This year we did not make any bargain, supposing that we could have our choice as usual; and when we had half the crop hauled she told us that we would have to pay the money, she was not going to take any molasses this year.

As soon as the children told us, Mr. Chaddock said, "You will have to buy another barrel now;" and he said it in the tone that means, "I told you so."

Well, I went right down to see Aunt Jane, and she said, yes, she wanted the money, and she wanted it "right away." She advised me to go to town, buy an extra barrel, engage the molasses at some store,

etc., but I thought I knew a trick worth two of that. I came home, took the horses and buggy, and Mollyony, and I drove around on the prairie and engaged all the molasses we had to spare. We left home at one o'clock, and came back at four. The folks will bring their jars and kegs here, and we will take them to Aunt Jane's on a load of cane, on Monday. Aunt Jane will measure the molasses into their vessels, they will come and get their molasses, without my touching it at all; they will pay me, and I will pay Aunt Jane for making it. No worry at all, no bother, every thing fair and square, and everybody in a good humor. Here was a first-class chance to worry, but I lost not a wink of sleep, the matter being all straightened out before sleeping-time came.

Vermont, Ill.

MAHALA B. CHADDOCK.

Mrs. C., that is the idea exactly, and I am with you at every step of it; but the thing that would worry me or make me feel a little anxious would be in regard to the quality of the syrup. If it were only equal to the samples of some I have seen, everybody would be pleased and happy, even if they had to pay more for it than store syrup costs; but if it didn't happen to be real nice, what then? May be Aunt Jane has the knack of making good syrup every time, no matter whether the cane is just so or not. If she *has*, that is the place to trade. I like to sell things as well as you do, provided they are real nice; but if they are *not* *real* nice, I always wish I were in some other business; and if you once get the reputation of dealing in nice honest goods only, then you can always sell readily.

THE SUNDAY QUESTION, AGAIN.

MRS. JENNIE CULP GIVES US ALL A GOOD LESSON IN TRUST.

FRIEND ROOT:—In a foot-note to sister Chaddock's reply to Nellie, on the Sunday question, you not only appropriated my text, but answered the question to *my* satisfaction; but as you are not a sister, and it was "the sisters" she wanted to hear from, I feel impelled to be as good as my word.

I am sorry to disappoint the little folks with the rooster story, for it is a big folks' story; yet it will benefit them to read it, especially if it should lead them to ask and trust the dear Father for temporal as well as spiritual blessings as it did me.

Sister Nellie, in my estimation your friend gave you the right kind of advice—"Trust they will do as well without you." Only carry it a little further; talk to the Lord about it; tell him you want to be diligent in business, and succeed, and you also want to be his faithful, willing child; and if in earnest, I feel satisfied he will make your pathway clear. "Remember the Sabbath day to keep it holy."

Saturday evening I dismiss my bees from my mind, as I do the rest of my week's work; on the morrow I give them no anxious thought; if they swarm I have them as I would take the "ox out of the ditch." We do not stay at home to see it fall in, neither should we stay home to see if the bees are going to swarm. If we are willing to suffer loss for Christ's sake, and his cause, I feel confident he is able and willing to hold our bees in check, if it is best, if

we ask and trust him. "Not a sparrow falls to the ground without *his* notice." "Even the hairs of your head are numbered." Our petitions are all heard if we come to the dear Father with childlike simplicity, in faith believing.

While husband was living I could not get the consent of my mind to like the bee business, on account of the anxious care he manifested, especially on Sunday. Hiring some one to stay at home on Sunday to watch the bees was as wrong to me as to stay at home ourselves, even if they were not in the habit of going to church. This was before queen-clipping came in fashion. After his death I could not get the consent of my mind to part with *one* of his bees, for, next to his wife and children, he loved them above every thing else. Before the swarming season commenced I was in company with some friends visiting, when one of the company laughingly threatened to tell a "rooster story" on sister H., a widow lady present, who was a dear friend of mine. When alone I asked her to tell me the joke they had on her about the rooster.

"Sister Culp, they may laugh all they please at me; it is no joke, but a grand reality. I go to my heavenly Father for temporal aid as well as spiritual blessings, and he gives it to me, for he knows I desire above all things to do his holy will, and many a time he has sent you over here in answer to prayer." And I could then recall to mind quite a number of times I had suddenly been impressed with the thought I ought to go and see Maggie. I would arrange and go, and she would invariably meet me at the door with a smile, and "I knew you would come." Now, her story is this:

"I had my little garden nicely made, and there was an old rooster that annoyed me very much. During the week I could watch him myself and keep him out. On Sunday, when time came to go to Sunday-school and church, I asked the Lord to keep him out while I attended. I then dismissed it from my mind, and went. After services, a friend invited me home to dinner with her. I studied a while to see if there was any thing in the way. Finding nothing, I said, 'Yes, I can go just as well as not.' We started and got part of the way there, when all at once my garden came in my mind. I stopped suddenly. 'No, I can't go.' 'Why?' 'I asked the Lord to keep the rooster out of the garden while I was at church, and the time is past up. I must go right home.'"

She arrived just in time; for while she had been losing, as she thought, unnecessary time in getting home, he had succeeded in getting in, but had done no damage. This little story, as related by the dear sister, set me to thinking as I had never thought before, and I concluded to go to the Lord for aid in temporal things, and not go, either, in an off-handed manner, as I felt I had been in the habit of doing. My bees give me no more anxious care on Sunday than do my cow and chickens; and if I have ever lost any thing by attending Sunday-school or church, I am not aware of it. I never allow them to keep me at home on Sunday.

Sister Chaddock says religion is a sentiment. With me it is a faith, a trust, a confidence, a *grand reality*—more to me than father and mother, husband and children, houses, land, bees, or any thing else you could enumerate. Shorn of it I should be of all persons most miserable. But with the conscious indwelling of the Holy Spirit in my heart I

have joy, peace, and rest, which the world can not give nor take away.

Thanks, sister C., for your kind sympathy. It is true, I am alone a great deal of the time. It is now near 10 P. M., and I have not seen a human being to-day, which is often the case, but I am not lonely. I miss the sweet companionship of husband, daughter, and mother, all of whom crossed over to the "ever green shore" within two and one-half years of time. But the assurance that they are safe and happy, free from care and sorrow, is a wonderful comfort to me. A few more days, if faithful, I shall join them, never to be separated.

I am glad you like me, for indeed I do appreciate it, and must say, in return, I like all the sisters, and have a kindred feeling for the brethren too. Strange, isn't it?

I see you are a little disposed, like the editor, to make fun of that maple-sugar feeding. He said I "fed it with a vengeance." I do not think he had any idea how much I fed—just guessed at it. I will tell you, and you can keep still about it. To begin with, my bees were not like Pharaoh's lean cattle; they did not need much *fattening*. I bought only 50 lbs. in cakes; had 28 colonies of bees, so you see it did not average 2 lbs. to the colony. Frost killed the fruit-bloom, so there was no honey, and that "maple sugar" carried them over to the white-clover flow, and there was enough taken off, when the surplus-boxes were put on, to furnish the three children all the maple sugar they wanted, all summer.

Hilliard, Ohio, Sept. 23, 1885. JENNIE CULP.

GRADING HONEY FOR MARKET.

DOES IT PAY TO BE STRICTLY HONEST IN SELLING HONEY?

EVERY thing you say on that subject (page 602) is true. I do not doubt that corn story. As it pays to have a perfect article, it also pays to have the superior and inferior by themselves, with prices to suit. This leads me to tell how I market my honey successfully. Springfield, Ills., is my principal market. Methods of marketing there, and here near home, are different. There, customers expect to pay what is asked them, and they take fluctuation in prices as a matter of course. But here, if I sell at a certain price one year, I find it very hard to ever rise above it. For that reason I have endeavored to keep the home price at 15 cents in any quantity. In doing that I am perpetually accosted with, "Why, I got honey last year for 12½ cents." Some who always like a choice article pay me my price without a word; but, how shall I suit the other class? Thus: I always put choice grades on exposition in Springfield. Two of the best merchants there are now selling for me on commission. My honey generally excels, and is never excelled by any lots that ever go there. Consequently my honey always gets the highest price. If *mine* will not sell, none will. I have learned this by experience, and I know it is so. My honey is now bringing 18 to 20 cents retail, which is 3 to 5 cents higher than other section honey is selling. Both these men have refused honey that they could get on better terms, in order to handle mine. Col. W. is the choicest dealer in the city. His customers know that they often pay him higher prices than they would have to pay elsewhere; but they also know that they always get a first-class article

from him. Well, the colonel has, at times, turned off several lots of honey, hoping that I would come along. About a month ago, when I stepped into his store for the first time this year, a conversation followed, part of which is in substance as follows:

"Colonel, do you want to handle some honey?"

"Why, yes, if it is nice. What is the quality of the honey? as nice as in previous years?"

"Yes, sir; fully as nice."

"What do you want for it?"

"Oh! well, about 16 cents per pound."

"Why, you are a little high, aren't you? There was a man in here the other day, who said he would bring in a sample of section honey that he offers at 12½ cents."

"Well, I do not want to sell mine at that yet awhile."

"Well, I should like to handle some of your honey, but they are selling it all around here at 15 cts."

"Will you sell some for me on 10 per cent commission?"

"Yes."

"Then I will send in a case next Tuesday."

I sent in the case of honey, and he put the price at 20 cts. per lb. I do not know whether that man brought his sample of honey or not; but when I was in three weeks later, the colonel had not bought any of it.

There! do you see it? But, what about that cull honey? Why, when everybody objects to my regular home price, I tell them about said cull honey, and, "Come and look at it." If they are a little slow to do so, I take it to them and say, "Here is some honey as good as any; but you see it does not look as nice as the other; this box is crooked; that one is bulged; this one is not all sealed over; that one is pretty dark; it does not market very well. You may have it at 13 cents." I always sell that honey to some one. The quantity of this inferior article is surprisingly small. Yes, all you say about grading is true. But there is another thing comes in here, which I want to talk about, although I am making this letter longer than I intended. Will you please indulge me? It is this:

BE A MAN OF YOUR WORD—BE HONEST.

At our dinner-table not long ago the dealing of certain men came up in conversation. A farmer near here sold a lot of cattle, to be delivered on a certain day. He turned them on to a freshly blossoming clover-field the day before, in order to make them weigh heavy, and in violation of contract too. It would have been bad enough if no such stipulation had been made. He on other occasions had been guilty of like tricks. I immediately exclaimed just what I felt—I would not have men think such things of me for all the fortunes I could make by it. I am not alone in this matter. There is one man in Springfield I like to deal with largely on that account. Once when I was settling up with him he said, "That jar of extracted honey weighed 22 lbs."

"You are surely wrong, Mr. Wright. It weighed only 20 lbs. on my scale."

"Well," said he, "now since you mention it, when I sold it I weighed it with a dipper in. I remember now of taking it out afterward. I did not notice what I was doing at the time."

I could easily have made 25 cts. by remaining silent, and he would never have known that I knew he was wrong; but, bless your heart! I would. My conscience would not have let me forget it. That is not all; I think Mr. Wright knows he can trust me.

and Col. W. as well. I would regard a person correcting a mistake thus for me as a pretty reliable fellow. Now, when I offer a man my cull honey, I tell him I can not sell it at a first-class price—that this is why I offer it so low. I do not tell him that “my regular price is 15 cts., but I will let you have it for 13. Please do not say any thing about it.” It would be just about the trick of a certain grocer in our town. He is one of the best business men in the village. He is as good a hand to attract custom and build up a trade as I ever saw, except in this feature. This, people can not but find out, and some men will not be lied to—not more than once or twice. Those who trade with him will not trust him, and they sometimes let him know it too. How could I endure such a reputation, even if nothing else were involved? To say nothing of its moral phase, such double dealing will injure, and often ruin one's business. It has ruined the business of one man I know, who once had the largest run of custom in the place. Suppose I sell A a good lot of honey at 15 cts. per lb., and B, an inferior one at 13 cts., but give him the impression that he is getting a favored bargain. For even second-rate honey, mine is called “so nice.” A happens to inquire of B how much he paid me, and B tells him. A comes to me with a complaint that I dealt unfairly, as he would have reason to do. I tell him the true reason I sold B that lot at reduced price; he carries it to B, and B in turn throws it up to me. How would I feel? Both would have just reason never to trust me again. Such transactions leak out, if practiced. No! it will not pay to deceive thus. I will tell the truth so plainly that men will know I am dealing squarely. I do not claim to stand pre-eminent and alone in the matter. I only want to show that it pays to be a man whose word is pure gold.

In your talk about grading products you struck a point whose importance can not, it seems to me, be overestimated, and one so true that I felt prompted to show by personal experience how true it is. This last subject seemed so nearly related that the former appeared incomplete without it. I intended to touch on some other matters, but, as usual, my letter has grown so long that I must stop right here.

Geo. F. ROBBINS.

Mechanicsburg, Ills., Sept. 23, 1885.

Friend R., your article is not a bit too long, while you teach such lessons as the one given above. I have often thought of these very things you mention; and while I think of it, I must confess that a man lowers himself in my estimation just as soon as he begins to tell me that he will let me have things so and so, if I won't say any thing about it, and things of like nature. I have sometimes told such men that I did not want goods lower than other people paid; and they would look up at me in surprise, supposing, of course, that all men are little and small, and greedy for every copper they can get or save by hook or by crook. Of course, I am sometimes told that I can have prices so and so, because of the unusually large bills that I make. That is a different matter. The man who is tricky, succeeds eventually in tricking himself; and, worst of all, the poor fellow never finds it out until he has tricked himself out of business, and oftentimes out of a home.

PLANT-LOUSE NECTAR AND BARK-LOUSE NECTAR.

PROF. COOK TALKS TO US ABOUT CALLING THINGS BY THEIR RIGHT NAMES.

PROF. COOK:—I send you a sample of honey, or bug-juice, that the bees have been gathering at a fearful rate for the last fifteen days. Some swarms have gained 30 lbs. I never saw bees work faster. They drop on the alighting-board by the hundreds, heavily laden. The queens are laying as much as they would in June. They have brood in all stages, and plenty of it. Give them empty combs and they will fill it right up with bug-juice and brood.

It has been July weather all of this month, with the exception of a few days. We have had two frosts this month—one the 7th, and one the 22d. The bees are building new combs, and lengthening out cells as much as they would in June or July. I have taken off all sections, to keep them from putting this stuff in them.

Bees have not made much honey since the 10th of August, although we had a good yield from raspberry, clover, and basswood. They are now going it on this. I don't know what you would call it. They get it off blackberry, this year's growth. The top leaves are all curled up in a bunch, about the size of a man's fist, and there is a bug, or louse, on the leaves, very thick. The hind part of them is white. The bees are swarming over the briars as thick as they would over a field of buckwheat in full bloom.

I live near the old pineries that have grown up to blackberry and raspberry. There is one thing certain—we shall have plenty of young bees to go into winter quarters; but, how about the wintering part on this kind of stores? I should like to have your opinion on this. My opinion is, that it is going to be bad stuff to winter on. My bees had enough to winter on before they commenced on this. I fed a few swarms upon sugar syrup. I wintered last winter in cellar. Would it not be better to winter on summer stands packed? If it should be an open winter, so they could have a light once in a while, they probably would go through all right.

Orona, Mich., Sept. 28, 1885.

L. REED.

The following is Prof. Cook's reply:

With the above letter came a half-pint bottle of nice-looking honey which, though not so light as clover honey, was considerably lighter than that from goldenrod or asters. I tasted of the honey thoroughly; and while I do not pronounce it by any means of first quality, I do think it is quite palatable. That I might have the judgment of others, wholly disinterested in the matter, and wholly unprejudiced by previous knowledge as to the source of the honey, I asked three members of the college faculty to sample it. All said, that, while they did not consider it equal to what I had usually given them, they thought it quite pleasant. As one gentleman said, “From fair to middling.” As any one familiar with entomology will see at once, this nectar is from plant-lice (family *Aphidae*), and not from scale-lice or bark-lice (family *Coccidae*).

Plant-lice are very common, there being few species of plants that do not harbor and nourish some species. Their presence is often denoted by the presence of ants passing up and down the plants in quest of this very nectar, which they, at least, pronounce pleasant and wholesome. These plant-lice are always active, are frequently seen to move about on the plants, and in almost all colonies some, usually but few, have wings. What a wise provision! The development of wings is ever at the cost of nourishing material, and so, unless needed, had better be absent. Thus they are wanting except in a few, which may fly away and so prepare to distribute and the better propagate the species. We bee-keepers wisely copy from such examples given us by nature; and so soon as our queens have done

with their wings—after mating is over—we cut them off. We see this is not against nature; and he who reasons that such queens are not just as acceptable to the bees, opposes both reason and experience.

These plant-lice are flask-shaped, and often oviparous; that is, the eggs hatch within the parent, not outside (oviparous), and these young, when hatched, are born at once, and are not nourished for a time by material from the blood of the mother (viviparous), as are the highest mammals. A little watching in the summer, or on house-plants in winter, will demonstrate this statement. The young lice will be seen at the moment of birth. Outdoors, the last females of the season lay eggs (oviparous), which pass the winter in some crevice, and hatch as the warmth of spring excites development. These plant-lice are also agamic, or illustrate the law of parthenogenesis. Thus they are specially interesting to bee-keepers, who witness the same law in the development of drone-bees. All the summer broods of plant-lice, and there are several, are composed wholly of females. If any of these are captured at birth, and placed at once singly on a plant suitable to their growth and development, each one will mature and produce, or give birth, to many lice. Indeed, our secluding them is quite immaterial, as the closest scrutiny will find no males till fall, when males and the oviparous females appear and mate, antecedent to egg-laying. Plant-lice work almost wholly on the leaves or green tender twigs.

Mr. Reed speaks of the leaves curling up. This is not uncommon. In many cases the leaves retain their shape, but seem to become enfeebled, and the plant dies. In some cases—indeed, quite frequently—the leaves curl up and die. In a few cases, as on the elm and poplar, galls are formed. The curled leaves and galls must serve as both food and house for the lice. Thus such plants obey literally the beautiful commandment, "If thine enemy hunger, feed him," for such plants bestow both shelter and food upon their most hurtful enemies. Nearly all of these plant-lice secrete nectar, some from two tubes (nectaries) which protrude obliquely up and back from the abdomen; others, and perhaps all, from the general surface of the body. This is a secretion; and it experience proves it to be always wholesome, it should not be denounced or regarded with disfavor any more than milk, which is wholly analogous in its origin. This nectar serves the lice in attracting bees, ants, and wasps, which act as sentinels to keep birds and predaceous and parasitic insects from destroying the lice. At the same time, the nectar serves the bees and ourselves as food.

I have often called attention to the difference between this plant-lice (*Aphis*) nectar, and that from the bark-lice. While the former is pleasant and wholesome in all cases, so far as I have examined, the latter (which comes from the flat, scale-like, motionless bark-lice) is bitter, strong, dark, and unwholesome. It is certainly unfit for table use, and I should not deem it fit food for bees.

As to Mr. Reed's query, I should have no fear in using this honey for winter stores, even with the bees in the cellar. Should they die with this honey, I think they would die with any other. I should not be as willing to have my hives stocked with this bark-lice nectar, such as was so common a year ago; yet several used it in cellar wintering, even last winter, with entire success. It may be, that if every thing else is all right, such food would an-

swer; yet I should be afraid of it. I dislike to feed my bees what I would not eat myself.

I hope, Mr. Editor, we shall call these substances plant-lice nectar, or secretion, and bark-lice nectar, or secretion—not "bug-juice." The latter term has neither science, accuracy, nor euphony, to recommend it.

A. J. COOK.

Agricultural College, Mich.

Friend Cook, we thank you for making this distinction: but it seems to me that the name you suggest is not much of an improvement—that is, so far as pleasant suggestions are concerned. I do not like the word louse or lice, and I never use it if I can avoid it, although I have placed it at the head of this article. Can you not suggest a name that does not have any such unpleasant term about it, especially when speaking of honey to those who know comparatively little about such matters? I do not like to see my friends turn up their noses when I am explaining the wonders of the bee-hive or the forest. Why not say, bark-aphis nectar and plant-aphis nectar? that is, if we must use the word nectar, when nectar seems such a misnomer for the greater part of these products. Honey-dew is not the word, for two reasons: it is not dew nor is it honey. Now, before we settle down upon a name, can't we have one less objectionable? For my part I would have it Latin, rather than to awaken disgust when trying hard to do quite the contrary. I am very glad of the important facts you give in this wonderful matter of these secretions from insects.

DRY FÆCES.

FRIEND MILLER GIVES US SOME PRETTY POSITIVE FACTS IN THE MATTER.

PROF. COOK has mentioned my name as sending specimens of dry fæces of bees. I merely forwarded to him specimens sent me by Mr. S. Corneil, of Lindsay, Ont., which were put up so nicely, and which were such good specimens, that I felt sure Prof. Cook would be interested in seeing them. I am not interested in the discussion about dry fæces—perhaps not as much as I ought to be, for I confess that I am ignorant of the exact bearing it has upon bee-keeping. Perhaps Prof. Cook or Mr. Corneil will inform us on this point. The most I know about it is, that Mr. Corneil, with his usual painstaking character, has been trying to show that bees can and do void fæces dry, and that Prof. Cook has been for years just as strongly opposing, only latterly admitting that they may exceptionally do so. I don't know that I care two cents which theory is correct, and would hardly enter the lists with any less noble foe than Prof. Cook, whom, with all my respect for him as an author and scientist, I hold in still higher esteem as a friend and brother. And I now enter the lists only so far as to state what has come, without seeking, directly upon my own observation among my own bees. If Prof. Cook had been here when my bees took their flight last spring I am not sure but he might have said that dry was the normal, and liquid the exception. I am not mistaken, I think, as to what I saw, for I have often seen the bees in the act of voiding, both this and other years, and have seen thousands of specimens such as Mr. Cor-

neil sent, both on the hive and in the vicinity. I presume I could even now find instances which the summer's rains have failed to wash away. I remember one hive last spring (which was, however, exceptional), in front of which the ground for the space of perhaps two square feet was covered so thickly that I am not sure but less ground than faeces was to be seen. It seemed as if the whole colony had by one consent emptied themselves just as soon as fairly away from the hive; and I doubt if there was among their droppings a single one that would have been called liquid. The cylindrical form could be plainly seen. Without knowing what may be, elsewhere, my testimony for this locality would be, that bees usually void faeces in liquid form, but the dry form is very common.

WAX-EXTRACTOR.

After I sent to GLEANINGS an account of my sun wax-extractor, there were cooler days, in which the wax utterly refused to run, and I adjourned the inside gearing to the kitchen stove, where it acted to my entire satisfaction. To any who have not large quantities (indeed, I am not sure but it will work well with large quantities), and who are obliged to use fire heat, I would recommend for trial the following:

Take something in the form of a dripping-pan, with one corner torn open; put it in the oven of the cook stove, with a chip or bit of wood to raise the back part of it. Let the open corner project out of the oven, and place on the floor a vessel to catch the drip; throw in the pan your wax to be extracted, and that's all. Don't be in a hurry; all the better if it melts quite slowly; and if the fire be pretty hot, one or both oven-doors can be wide open.

CLEANING WAXED UTENSILS.

In various ways it will happen that milk-pans, crocks, etc., will be more or less daubed with wax. The attempt to clean them as dishes are ordinarily washed will be an ignoble failure. Don't try to wash them with *hot* water. Here is a dish in which some honey has been melted, and a little wax has been in it. If you attempt to wash it with water hot enough to melt the wax, you will succeed only in having the dish more thoroughly waxed. But wash off first the honey with cold water, at least cool enough so it will not affect the wax; then wipe dry, and heat till the wax melts (if the dish is not too large, a good place is in the stove oven), then take pieces of newspaper, and, without allowing to get cold, simply wipe the dish clean of wax.

CAN BEE-GLUE BE UTILIZED?

A good deal of propolis will be accumulated in cleaning off sections. It makes good fuel. Can any better use be made of it? A year or two ago I conceived the idea of melting it up and coating honey sheets, or quilts, with it. The attempt was an utter failure; but in heating the bee-glue I found a liquid settling on top, which, on carefully pouring off, I found to be very nice beeswax. As I had a large quantity of bee-glue, I obtained, if I remember rightly, about 7 lbs. of wax. C. C. MILLER.

Marengo, Ill., Oct. 1, 1885.

I hope the friends will excuse me for taking this matter up again, after once saying I thought it best to say nothing more about the subject for the present. Friend Miller, however, gives us some facts from experience that have not been given before. I have felt sad to see the parties on both sides

of this question talk so vehemently, and, I must confess, a little stubbornly, sometimes, when it seemed to me, as friend Miller expresses it, it did not matter very much who was right or who was wrong. I should like to put in just a word, though, for our friend Cook. If I am correct, the principal point at issue was, Do bees drop dry faeces on the bottom-board of the hive while in winter quarters? The friends on one side of the question insist that they do, and that that is the healthy and normal way for bees to winter. Even friend Miller does not claim to have found dry faeces on the bottom-board of the hive, although he has found considerable quantities in front of the hive, that might almost be said to be dry faeces.—In regard to wax-extractors working by the sun's rays or by putting in the oven, on the ingenious plan suggested above, do not all such arrangements leave considerable nice wax among the debris? I agree with friend Miller exactly, in regard to cleaning wax from utensils. Trying to scrape the wax off with a knife is the poorest plan in the world, and it annoys me greatly to see the women in our wax-room undertake to work in this way. I have for some time been aware that what is called "bee-glue" contains considerable nice wax.

KILLED BY BEE-STINGS.

WHAT WE CAN DO TO AVERT SUCH CATASTROPHES.

THE following sad case seems to be authentic, without question. An important thing for us as bee-keepers to do is to decide upon the best course of action when such things do happen, although it is only once in a great while.

SINGULAR DEATH OF MRS. FADER, A PENNSYLVANIA BEE-KEEPER'S WIFE.

Thomas Fader, of this place, keeps several hives of bees in his garden. Yesterday forenoon he was at work among his bees. A man with whom he had some business dealings, called at his house to see him. Mrs. Fader went out to call her husband into the house. As she approached the bee-hives a number of bees flew into her face, and she was stung several times. One of the bees stung her in one of her nostrils, and another one stung her on the upper lip, at the base of the cartilage dividing the two nostrils. Mrs. Fader's cries brought her husband to the spot. He extracted the stings and applied wet earth to the wounds. He went with his wife back to the house, and had no thought of any consequences resulting from the bee-stings more serious than the swelling and pain. He left his wife in the kitchen, applying ammonia to the wounds, and entered a front room, where his visitor was. A few minutes later he heard a heavy fall in the kitchen. He ran out, and found his wife in convulsions on the floor. Her nostrils were swollen shut, and her lips were twice their natural size, and had turned dark blue. She breathed short and quick through her mouth. Her face was so swollen that its identity was entirely lost. Mr. Fader hurried his visitor after a doctor, but before one arrived his wife died in her husband's arms. The doctor said that the stings in her lips and nostrils had sent a shock like electricity to her brain, and from that to her lungs and heart, so severe that she was unable to rally from it. Mrs. Fader was twenty-eight years old. It was but forty-five minutes from the time she was stung until her death.—Gouldville (Pa.) *Special to New-York Sun.*

At first thought it almost seems as though no one was at fault in the above transaction, and that there was no way of averting such

an occurrence, or of saving life where the symptoms are so severe. Lest any one be frightened by it, however, I will say what I have said before, that deaths from bee-stings are nowhere near as common as deaths from accidents from horses. Accidents are liable to happen with almost any kind of the domestic animals; but for all that, we want to see what can be done toward saving life. Had our poor friend who lost her life been accustomed to bees, or had had her thoughts about her, I hardly think she would have gone among them when they were stirred up, as they evidently must have been. I have seen people push ahead into an apiary when I should have known, before I came within several rods of the hives, that one would be sure to be stung if he did not retreat. One who is familiar with bees learns to tell very quickly when it is safe to go among the hives. Another thing, when I decide to go among angry bees I always shield my face by pulling down my hat, and putting my hands before my face. This action alone seems to have considerable effect in keeping the bees away from the eyes and nostrils. I seldom get stung in the face nowadays. If at all, it is on the back of my neck or the back of my hands—possibly on the ears or forehead. The swelling from a bee-sting may obstruct the breath; but usually in such cases, I think that with sufficient presence of mind an attendant ought to be able to keep the passage to the windpipe open. In cases of swelling of the throat from quinzey, the handle of a spoon is often used for this purpose. It may be, however, as stated in the above clipping, that death resulted from some other cause than suffocation.

It is a good thing to give place to these accounts, that people may be warned, where they are unaccustomed to stings, or where much pain and swelling follow, to be careful about recklessly exposing themselves when bees are infuriated from any cause, as they must have been in the above case. I do not believe that I would resort to ammonia or any thing, unless it is cloths wet in cold water, to allay the fever. Of course, the stings should be extracted promptly; but it should be done without squeezing the contents of the poison-bag into the wound. The blade of a knife is often the readiest means of doing this.

PREVENTING AFTER-SWARMS. AGAIN.

FRIEND DOOLITTLE GIVES US SOME ADDITIONAL
IDEAS IN THE MATTER.

ON page 600 I see Bro. Heddon could not be persuaded to adopt my plan for prevention of after-swarms, and does not think any will tolerate it when once they "get the hang" of just how to use his method. Well, as far as Bro. H. is concerned I presume I ought not to expect him to even try the plan I gave, for he "can not be persuaded" to try friend Root's chaff hives, nor even the Simplicity size of the L. frame. Again, he must have Heddon's hives, honey-boards, shade-boards, non-erasing crayons, and that 15 to 25 pound stone, all of his own, so I am content to let

him have them, and to use his plans without further molestation; but for the benefit of those who use chaff hives, tenement hives, house-aparies, etc., I wish to tell them how nice the plan I gave on page 557 works. Many have complained of the unwieldiness of the chaff hive in swarming-time, and urged that as a reason for not adopting it—especially the ladies, who had nearly their match in trying to move even an eight-frame Langstroth hive. To all such I would say, that I have come to the conclusion that chaff hives are an actual necessity for outdoor wintering here at the North, and in the future I expect to use no others, except for those I winter in my bee-cellar. That the plan given on page 557 gives all the advantages that Bro. Heddon's plan does, I think no one will deny; and it is especially adapted to chaff hives, as I have proven during the past three seasons. The box used for carrying the combs need not weigh over 5 lbs., and a handle convenient for carrying can be readily attached to it, so that any lady can use this plan without fatigue, no matter what hive she uses, while the chaff hives, large tenement hive, or the Townly chaff-packed dry-goods boxes, are just as easy of manipulation as any. In short, I have never used any thing about the swarming of bees which worked so perfectly, and pleased me so well, as this plan for the prevention of after-swarms.

WHERE THE BEES CAME FROM TO SWARM ON THE
HEDDON PLAN.

ON page 600 Bro. Heddon wants to know, "Whence did that colony get bees to swarm with?" referring to a colony treated exactly as he says they should be. Well, I will try to explain. When I first began to try the removal plan to prevent after-swarms, as given years ago, I noticed that many colonies would often not stir at all for two or three days, while others would commence to work their new location at once; and in either case such a hive was sure to swarm. Once in a while one would keep on giving off bees, which left the hive in a straight line, until the colony was fearfully reduced, in which case no swarm would issue; but these latter were the exception rather than the rule. One other item bearing on this point: Several years ago I gave in GLEANINGS how I was led to form nuclei by taking a frame of brood, with queen and bees from any hive, and placing it where wished in any empty hive, the bees, as a rule, would adhere to the queen; while if no queen was given, all the bees that could get back to the old hive would do so. From this I learned that a colony having cast a swarm looked upon their queen-cells the same as any other colony did on their queen, after which I carried a frame of brood and bees with a nearly ripe queen-cell, and placed in an empty hive to form a nucleus, when in most cases the bees would not return. Now, this has a direct bearing in this locality on the moving of all hives which are especially anxious about their queen or cells. Just as soon as I would move a hive on the Heddon plan, the bees would stop issuing from it in less than one minute after it was placed on the new stand, and there they would stay for two days, when out would come a swarm. In one instance I moved a hive in the middle of a bright day, and immediately the bees stopped drawing off. For three days I watched to see a bee leave or return to that hive, and not a bee was seen. At ten o'clock the third day, or ten days from the time the first swarm left, they swarmed again,

when I cut out all the queen-cells and returned them. They now went to work with a will, and gave me 62 lbs. of honey in sections. Again we had much rainy weather during our swarming-season, so that the day on which the old colony was to be removed would be rainy or cloudy, so no bees would be flying; in which case, if moved, of course no bees would be in the field. I generally left them until the next day; but on one occasion the 6th, 7th, 8th, and 9th days were all rainy or cloudy, so I waited till the morning of the 10th, when several colonies were moved, and all swarmed soon afterward, owing to the sun coming out bright and warm. In this latter case there can be no help in the matter where any hives are manipulated, and I think even Bro. H. can see plainly where the bees come from. In all cases where I could be on hand when the young bees were having a playpell in the afternoon of the 6th day, and move the hive when said bees were out the thickest, I could make a success of the Heddon plan. G. M. DOOLITTLE.

Borodino, N. Y.

Friend D., you seem to have your own notions, and friend Heddon has his own notions, and each of you succeed quite satisfactorily, because your ideas and ways are all in accordance with said notions. I have often noticed the way in which you say it works when you move a hive away during cloudy or rainy weather; but your idea in regard to moving a hive while they are out playing, is something I never thought of; and without question the idea is a valuable one. By this means we can get a nice lot of young bees, just the right age to make the nicest kind of a nucleus.

BEE BOTANY,

OR, HONEY-PLANTS TO BE NAMED.

LEAF-CUP.

I SEND some seeds, leaves, and flowers of a plant to be named. It is a wild autumn flower growing in the woods. At the present date the bees are at work on it quite lively. It is an annual, growing 3 or 4 feet in height. While watching the bees at work upon it I could not see that any of them were gathering pollen. Besides this plant, bees are now working quite fast on buckwheat, also on smartweed and other kinds of wild autumn flowers. There is an immense lot of smartweed this year. All through the first part of the season, the bees could not do much; but when basswood bloomed they worked finely. CHARLIE L. GREENFIELD.

Somerville, O., Sept. 23, 1885.

Prof. Devol says of it:

The specimen sent is leaf-cup (*Polypnia Canadensis*, L., variety *discoidea*, Gray). It is a coarse, broad-leaved, climbing plant, without value, growing in shady ravines and moist woods. It is peculiar in having the corolla in the few florets that produce achenia (seeds) reduced to a hairy ring around the base of the style. W. S. DEVOL, Botanist.

VIRGIN'S BOWER (CLEMATIS VIRGINIANA).

I should like to know what kind of plant this is. It is a vine, and is covered with flowers; the bees work on it all day in great numbers.

Cornwall-on-Hudson, N. Y.

J. B. CLARK.

Prof. Devol says:

The plant is the common virgin's-bower (*Clematis Virginiana*, L.), the pretty wild vine growing along the rivers and fence-rows, covered in mid-summer with fine white flowers, and in autumn with fluffy, feathery balls of a creamy-white color, so beautiful for winter decoration. It is quite easily transplanted, and makes a beautiful arbor, screen, or trellis plant, a number of branches from each root growing from 10 to 30 feet in a season. The downy balls are caused by the plumous tails attached to the fruit.

W. S. DEVOL.

Ohio Agricultural Station, Columbus, O.

FALSE STATEMENTS IN REGARD TO THE HONEY BUSINESS OF OUR COUNTRY.

As a protection to our bee-keeping population, we propose in this department to publish the names of newspapers that persist in publishing false statements in regard to the purity of honey which we as bee-keepers put on the market.

MR. C. F. RAYMOND, of Cleveland, Ohio, sends us the following, taken from the East End *Signal* of Sept. 19, and credited by them to the Chicago *News*:

WHAT BEES ARE COMING TO.

A Michigan apiarist has succeeded in teaching his bees to make honey from glucose. He began by setting pans of syrup near the hives, and as the bees became habituated to sucking sweets from them he daily reduced the amount of syrup more and more and filled in with glucose, until finally the bees were sucking only straight glucose, and making honey at an astonishing rate. The small, bare-footed son of the apiarist, who innocently "gave the old man away" to a Detroit reporter, said that the bees made about twice as much honey under the new method as they used to when they had to spend most of their time gathering raw material from flowers and clover-blossoms.

We have long thought that bees were too primitive in their methods. We have had a sort of intuitive belief that they were capable of high civilization if man would only influence and direct them in proper and useful channels, but never until now have we had substantial proof of it. The Michigan apiarist, however, has opened a field so broad that it seems almost boundless. The possibilities suggested by his successful experiment are bewildering. If by straining glucose through bees a man can get honey, why may he not strain chalk and water through them and get choice milk and cream, or banquet them on soap-grease and get prime Orange County butter? Why may he not feed them on logwood and cheap alcohol and obtain a first-class brand of port wine? or, by substituting some other ingredient for the logwood, get a "superior article" of any other convivial beverage?

It is not well to educate the bees too highly all at once. But if we carry on the civilizing process gradually there is no reason why the bee may not become one of the most useful factors of future progressive civilization.

The writer of the article seems to recognize the story as a fraud, judging from his pleasantry; but after all, it seems to me that even pleasantry is not the thing where credence in such reports may be a wholesale damage to a large number of innocent people. If the *Signal*, and all other papers that have given such reports a place, would come out frankly and correct the impressions to which they have given publicity, and state that glucose is not honey, and feeding it to bees can in no way make honey, any more than feeding chalk and water to a cow can change it to milk, they might do us some service in righting the wrong they help to disseminate.

He that is faithful in that which is least, is faithful also in much. LUKE 16 10

MYSELF AND MY NEIGHBORS.

Thou hast been faithful over a few things, I will make thee ruler over many things.—MATT. 25:21.

Cast thy bread upon the waters; for thou shalt find it after many days.—ECC. 11:1.

I FELT as though I wanted these two texts, little friends, to indicate what I want to talk about to-day. The thought was something like this: That men go along a great while, sometimes, trying hard to do right, and it does not seem to amount to much of any thing. Finally, however (it may be years after, and when we had forgotten all about how hard we tried to say, "Get thee behind me, Satan,") the reward comes. We had cast our bread upon the waters of this world long years ago, and supposed it was lost and forgotten. But here is a wave that brings it up again. Again, we may be growing in Christian graces, and we may be growing, too, in our ability to help the world along, and not know it or think of it. Do you remember in that passage where Jesus told the good folks that they had been helping him all along, and they did not know they had helped him at all? The text reads this way:

Lord, when saw we thee a hungered, and fed thee; or thirsty, and gave thee drink? When saw we thee a stranger and took thee in; or naked, and clothed thee? Or when saw we thee sick, or in prison, and came unto thee?—MATT. 25:37-39.

Now for my little story:

Our railroad company have decided to widen their tracks right here before our factory, and they are also building a new depot.

a good deal, I believe, for the accommodation of our business. In order to make the track wider they have had to cut down a hill; and to do this they are working right in front of our factory windows with a steam-excavator, if that is the proper name for it. It is a great ponderous engine made of timbers and massive chains; and in front of it there is a great iron scoop with massive steel horns that dip into the ground until it gets a mouthful, and then it drops it out on to one of the train of gravel-cars. As it is a new thing in our town, crowds of people gather around to see it dig through the hill. It really looks at first sight like some of the old sea-monsters, with its gigantic frame and monstrous head. This head it dips down into the hard stony ground, and roots up a small hill as if it were a hog rooting in a potato-patch. When it gets a load on its nose it swings its long neck around and drops the dirt in the right place, as if it were alive. Then it noses about to see where it will commence to root next time. Huber calls it "Great big angel." He has probably got his knowledge of engines and the angels his papa has told him about, a little mixed up; and I have wondered sometimes whether the term "angel" would be so much of a misnomer after all. It must be a messenger of mercy to the poor men who have for ages done all this hard work by back-breaking toil. When the operatives of this machine got it well started, so that every thing worked all right, smoothly and safely, the ponderous thing seemed to warm up with exercise, and to really put on life. The

great neck swings around so quickly that it makes the chains rattle like a tornado, and the massive beams creak and groan under the enormous strain of the heavy loads that that neck of iron raises up. One stands by and feels like lifting his hat with reverence toward the little man who stands perched up between the timbers forming the arch of the neck while he pulls the different levers that make the great machine do his bidding. How is it possible he can do all this without making a mistake? The great iron tusks, as they appear to be, strike in just the right spot, and go just deep enough, and not too deep. At this very instant the steam begins to do its work, as we have evidence by the enormous puffs. The earth trembles beneath our feet while the ground is rent and torn as if by a small earthquake. But the minute these great tusks reach the surface of the ground, the enormous power all of a sudden eases up; and as the machine swings around with its load it seems as quiet and obedient as a little child. Surely this man who manages it, and who has the trained eye, to skillfully direct this great power, must be a man of wonderful intellect; he must be a man of great education and skill. I gazed on him and then on the machine in wonder, and went back to my work, leading Huber, who obeyed his papa, but rather reluctantly. In the evening somebody was in the counter store, looking at a hammer. He was a very commonplace-looking individual, and one who spoke our language but imperfectly. Yes, he was the one who handled those levers and wheels and chains during the day. Was he a college graduate? No, but just as good a man in God's sight, and he may be better than a good many who have borne honors. He was a man who had probably been faithful in his every-day work, and his employers had learned by degrees to intrust him with important machinery; and at length he became an adept in his line, and could make that piece of mechanism for that particular work rattle and bang in a way that seemed almost frightful to bystanders; yet he did it with perfect safety, and with little danger of breaking or injuring any part of it. He simply did his duty in the place where God called him. Dear friend, are *you* doing your duty well and faithfully right where God has placed you? I want to come a little nearer home yet—am *I* doing *my* duty well and faithfully—casting bread on the waters some of the time, feeding my fellow-men for Christ's sake, and doing it all gladly and patiently? I am afraid I am not.

Since our last issue went to press I decided to visit the city of New York. It was a sudden conclusion to go. I told Mr. Holmes, my brother-in-law, that I wanted to stay only three or four hours. He gave me a severe talking to, and told me I had no *right* to go to New York and stay only three or four hours, even if I did feel like doing so. I concluded, after thinking it over, that he was right. It would be selfish for me to go so far, and stay so short a time, and that my duties toward my fellow-men and toward you, dear readers, demanded that I should stay at least a couple of days. In order to

save time, I rode with the engineer on a locomotive to our nearest station on the N. Y., P. & O. Railroad. Now let me digress a little.

For some time lately I have been making it a subject of prayer to God that he would give me more love toward my fellow-men, and he has been opening my eyes in that direction. It is true, that I occasionally have fits and spells of loving even my enemies, but, with sadness I say it, I have a good many fits and spells of *not* loving very much even my friends; that is, if I don't look out I keep dwelling on the weaknesses and imperfections of my fellow-men. Sometimes I get into a real bad spirit because somebody has heedlessly wronged me out of a few cents. I do not often say very much about it lately, for God has taught me to keep it to myself when I can not do any better. And he has also taught me to get out of this bad state of mind. I talked to you about it last month, you know. Well, I am naturally very bashful, if that is the word. I am afraid of people. I get notions in my head that they don't care any thing about me, and don't want to be bothered, when directly opposite is the truth. Jacob told me I could ride down on the locomotive when they went down to fill their water-tank, but I thought they would not want to be bothered with a passenger. I spoke to our agent about it, and I felt ashamed of myself when I saw how kindly he undertook to make arrangements for my going. Jacob told me they were all ready, and that I must hurry up and jump on. Ernest helped me to scrape up my few "traps;" and when I came to climb up by the engineer, instead of finding a gruff sort of swearing man, which I had pictured in my mind's eye, I found a very quiet, friendly, boyish-looking fellow who reminded me, by his hearty good nature, of some of my own German boys. I felt ashamed of myself; and when he offered me a part of his dinner, because he had noticed I had forgotten to bring any, I felt more ashamed still. In my talk with him I pretty soon found that he was the very engineer who was running the engine at the time our old friend Fred was killed. He knew of me through Fred; and when I had been casting bread on the waters by visiting boys in jail, I had been making for myself a warm place in the hearts of these sturdy laborers. I watched my new-found friend as he pulled the levers and handled the ponderous locomotive, moving it an inch at a time, if need be, and starting it up so gently that only a very small amount of power was needed, so that it seemed like a child in his hand. He, too, had been faithful in few things, and now the company intrusted him to the care of this great locomotive; and from what he said about Fred I knew he had been a great many years filling his place of important trust. Little did I think, when I went into our county jail and plead with these boys for the cause of Christ, that my work would be felt years after among these rough hard-working men along the line of our railroad.

When saw we thee a hungered, and fed thee? or thirsty, and gave thee drink? or in prison, and came unto thee?

AUNT KATIE TELLS US A WHALE STORY.

ALSO SOMETHING ABOUT CALIFORNIA ACROSS THE COUNTRY.

ABOUT five weeks ago we saw an account in a paper of two whales being seen off Port Harford, sixty miles away, and some one shooting at them with Henry rifles, and securing one of the whales. About a week ago we read in our local paper that a dead whale had stranded on the beach near Point Sal, twenty miles from here, and that it had four bullet-holes in it. Being so near, we concluded to pay it a visit. So we loaded up our wagon with tent, bedding, and provisions, and plenty of wraps (for the ocean breezes at the beach are quite chilly). After picking up a friend from Missouri, who had never seen a whale, we all joyfully rode along. We made a camp-fire beside a wayside spring, at noon, and made a cup of tea, and ate our lunch. Then we arrived at the beach about 4 P. M.

That the whale? Why, it looks like a monstrous black rock; and, see! it has a white tail. We soon got near enough to see that the tail had been "peeled," as the boys called it; that is, the fat, which was from two to six inches thick, had been cut off. The whale had stranded on its back, and the sea was dashing against it, so we were unable to see the head, the part we wished most to see; but we were told that the tide would be out in the morning, so after looking at the huge monster till we were tired, and feeling almost fear at the tremendous breakers as they dashed upon the beach, we retired back from the shore and pitched our tent among the sand dunes which extend along the beach at this place. By keeping to windward we escaped all scent, which is slight, considering the size of the object, and the time it had been stranded. We then got our supper. As we were sitting by the camp-fire after supper, one young gentleman who was among the hands trying out the fat, came up and invited the male members of our party to a coon-hunt; but being pretty tired, they declined. The next morning the boys told us they got four coons, and that as soon as a coon found himself chased he would make for the water; that one coon had caught hold of the dog's ear and had tried to hold his head under water, and that George had run out into the surf and helped get the coon, and that he got wet through. He got the coon, though, and that paid him for the wetting.

The tide had been down and up, and was now going down again; and as soon as it got low enough they were going to cut off the head of the whale so that they could turn over the body in order to get the rest of the outside fat, of which they had secured only about a fourth. They had 500 gallons of oil rendered out. We waited until 10 A. M., but the tide had not gone down enough to get at the head without getting wet by the breakers, so we did not see any more of the whale than we had seen the evening before; but we ran all around it between the waves, and some of our company went on top of it. Three men and a boy didn't occupy much space on that mountain of flesh. When first found it was quite out of the sand, and it was measured. It was 72 feet long, and 15 feet high. Every time the tide came up, the body settled into the sand, and it had flattened out till it looked like a black floor, big

enough, almost, for a skating-rink. The flukes at the end of the tail are put on opposite to what a fish-tail is, and each section which lay spread out upon the sand was about five feet by two, and about five inches thick. When they are angry they bring the tail flat upon the water, with force enough to smash a good-sized boat.

As we could not stay any longer we packed up and started back home. We showed our friend where the men used to haul the wheat raised in the Los Alamos and Santa Maria Valleys, to be shipped by steamer to San Francisco, until the railroad was built; and as we had come to the beach by one road, we thought of returning by the other road the men often took on their return, rather than meet the six-horse teams and the attendant dust. We had loitered about Point Sal until we found we couldn't get quite home that night, so we went on until we came to the Los Alamos Creek, expecting to find water as in olden times, but found it dry. So we followed it up until stopped by a fence. We then camped among some willows, and fortunately found water, borrowing some potatoes from a field near by, and there we found out why the creek was dry. It had been used to irrigate with. We got supper. We had been out longer than we had intended, so our provision-box was about empty, hence the potatoes. In the morning we found a gate, and passed through into a field, and soon found a road. It had been partly made, and was over quite a large hill. The men had to hang on to the side of the wagon with all their might, to keep the wagon from tipping over. You may be sure that I and the "little ones" did not ride until safely at the top. We had some sport laughing at the notices to trespassers, warning them not to cut timber on the place. As nothing was to be seen but brush for miles, we wondered where the timber was. After going along the road about three miles, and finding that we were going away from home, we felt uneasy; but as unbroken fences barred the way, we had to keep on or go back ten miles. We soon espied a man in a buggy, coming toward us. He proved to be an acquaintance, and the overseer of the ranch where we got the potatoes. So we told him we had added a "T" to each word of the name of our valley, to describe our condition, making it Los-t Alamos-t, and we mentioned the potatoes. He told us the road home, and said that was the right thing to do when one was hungry; viz., help yourself from a friend's garden, and that we ought to have driven up to the hay-stack near the field, and fed our horses. There is California hospitality for you.

While digging the potatoes our Missouri friend objected; but we told him that as we gave so often of our abundance to campers and tramps, when we were in a strait we only paid ourselves, always in moderation, of course. Our friend treated us to some of the fruit of the prickly pear, which he had in his buggy. The natives and Mexicans like them very much. It tasted to us like a sort of mixture of cucumber and musk-melon, quite eatable when nothing better can be got. We traveled three hours from the night's camping-place before we reached a road that led us home. We had camped ten miles from home, and at 10 A. M. were still ten miles from home. We were wishing that Bridget had some nice coffee made when we got home.

"Who is Bridget?" says the baby. We had to acknowledge that we were Bridget, so the coffee was not ready, of course; but we soon had some when

we did arrive, voting that we pretty nearly paid too dearly for the whale, but not quite.

Los Alamos, Cal., Sept. 7. AUNT KATIE.

Well, Aunt Katie, I have learned something from your little story, any way, for I did not know before that whales come along the coast of California. I find it also quite interesting about your trip across the country. I think your disposition must be something like mine. Whenever I go anywhere I always want to go back a different way. My wife objects, because she says I always get lost, or waste a good deal of time; but I tell her it is worth being lost, just to feel that you are on a road you never traveled before. I always like to be on a spot that is to me an "unexplored region."

GOOD REPORT FROM A JUVENILE.

40 GALLONS OF HONEY FROM 20 SWARMS; ALSO SOME OTHER THINGS OF INTEREST.

ACCEPT my thanks for the book you sent me. It was more than I expected or deserved. We make farming our chief employment; have not lost any time, to amount to much, from the farm, to tend bees, until this year. We make our own hives and frames, and can't afford to buy them. Last spring, on going to Pond Creek to improve some land, we carried 15 weak swarms (late after-swarms from last year), three new swarms, and two nuclei as a kind of experiment. I did not use any foundation or empty combs in supers. No one lived on the place. I went in company with my pa every ten or fourteen days (as we could spare the time from the farm and home apiary), examined each colony, made note of condition, date, etc., on front of the hives. We tried our slates, but the wind blew them down, and the rain washed the note off. We increased to thirty colonies by division; to avoid swarming we put on supers early in May, and had two colonies badly weakened by after-swarming (overlooked queen-cells). We have extracted 354½ gallons up to date. They have thirty or forty gallons in supers at this time, but we have no time to extract. We did not extract from brood-chamber after June 5th and 6th. We found at that time the queens had been crowded from the brood-chamber to the supers. The ABC book said extract. We did so. We placed brood-frames in lower story June 5th and 6th, and extracted 86 gallons. Imagine our surprise, on returning, June 17th, to find the front and side of nearly all the hives covered with idle bees building comb on the outside of the hives. We used the extractor and put on another super, and all hands went to work as nicely as ever.

Horsemint was in bloom, and waist-high all over the apiary—indeed, all over the country. On the 7th of August a neighbor carelessly let fire get in our inclosure. The dense grass, from knee to hip high, and dry from long drought, was soon in flames. The timely arrival of five or six neighbors saved our apiary from total loss. One colony was burned, several others badly damaged. One of the men had his hands badly burned in fighting the flames. Some of the trees 20 feet high had all their leaves burned off.

Last spring we killed two large rattlesnakes in our apiary, from which it takes its name. The rat-

tlesnakes in that neighborhood are as thick as pig-tracks.

We had no rain in Rattlesnake apiary from May 27th until July 5th; none since that time up to date. I wish to say to the juveniles, your letters telling of your little sisters and mothers make me envy your happy lot. My mother died five years ago, depriving me of a mother's care, and, dearer than all, a mother's love. My two little sisters, seven and eight and one-half years old, live with their aunt in Bell Co., Texas.

SAM. H. TERRAL.

Jones' Prairie, Texas, Sept. 14, 1885.

Why, my good friend Sam, if you have a locality where honey comes in at such a rate that your bees all build combs in front of the hives, it must be a "big thing" indeed. If such a thing ever happens again, you want to let the farming go, and stick right to the bees; sit up nights, do almost any thing, rather than let the bees lie idle during such a harvest as that.—We deeply sympathize with you in the loss of your mother.—I would have a piece of plowed ground around that apiary, broad enough to prevent the fire from running into it again.

MAKING BEES HATCH HEN'S EGGS.

AN UNPATENTED INCUBATOR.

WE live 200 miles southwest of Dallas. We have pre-empted us a little home four miles south of Lampasas, consisting of 19 acres. Our bees, 30 colonies, are in good condition.

Pa has invented us a cheap incubator. Take a simplicity wide frame, cover it with wire cloth, fill it with hens' eggs, then place in a strong swarm, putting a frame of unsealed brood on either side of it, and lift out and turn the eggs once in 24 hours. The eggs will need no moistening, as incubator-books direct, but the bees will tend to that. We have not hatched any quite out; but late last year pa suggested that if his queens hatched well under a hen we would try eggs in a bee-hive. So ma put in twelve, and they nearly hatched. The bees swarmed a week before time for them to hatch, and it came a cool rain, and they died in the shell. Ma broke the eggs and they had great big chickens in them. We are going to try more this season, and pa said he would say nothing about it until we hatched some chickens out; but ma thinks that some one else can try also, and be successful.

Lampasas, Texas. AMANDA ATCHLEY, age 12.

Well, Amanda, you have got something original, surely; but I am inclined to think, that, as a rule, sitting hens would be cheaper than a strong colony of bees. Unless the weather is extremely hot during the whole three weeks, I do not believe a colony would keep the eggs warm enough, unless you make a chaff cushion to fill, say an inch and a half or two inches of the space all around the wide frame; or, what will be simpler, and easier done, cut out the center of a chaff-cushion division-board. Tack wire cloth over this central hole, and put the eggs between the two sheets of wire cloth. A good swarm of bees would, without doubt, under favorable circumstances, hatch, say five or seven eggs. When hatched, take out the egg-shells, and you might use the

arrangement for a brooder, providing you put on double wire cloth, so the bees could not sting the chickens.

Every boy or girl, under 15 years of age, who writes a letter for this department, CONTAINING SOME VALUABLE FACT, NOT GENERALLY KNOWN, OF BEES OR OTHER MATTERS, will receive one of David Cook's excellent five-cent Sunday-school books. Many of these books contain the same matter that you find in Sunday-school books—eating from a plate, \$1.00 to \$1.50. If you have one or more books, give us the names that we may not send the same twice. We have now in stock six different books, as follows: *Alphabet*, *Sheep*, *Off*, *The Count*, *Eller*, *The Roby Family*, *Rescued from Egypt*, and *Ten Nights in a Bar-Room*. We have also *Our Homes*, *Part I* and *Our Homes*, *Part II*. Besides the above books, you may have a photograph of our old house in Paris, taken a great many years ago. In it is a picture of myself, Elsie, Eves, and Caddy, and a glimpse of Ernest. We have also some pretty little colored pictures of birds, fruits, flowers, etc., suitable for framing. You can have your choice of any one of the above pictures or books for every letter that gives us some valuable piece of information.

"A child's among ye takin' notes
An' faith, he'll print it."

WELL, little folks, while my papa's gone to New York, I'll just crowd myself up in this little corner, and give you a little talk on how to write letters. He won't know any thing about it until he gets home, will he? With your keen bright little eyes, and willing hands directed in the right way, I fancy you may be able to tell even some of the "big bee-men" something they didn't know before. Now just listen, and perhaps I can tell you how. When you sit down to write a little letter, read very carefully the fine print at the top of this page. It says you must write something new. That is a pretty hard task, isn't it? Some of our big folks find it so, at any rate. Now, as you have got lots of energy and a pair of eager little eyes, I believe you *may* beat your papas and mammas if you try real hard. Now I am going to give you a sample of a letter such as we don't want, because it has become stereotyped; that means, over and over again; see if it doesn't sound natural.

"My pa keeps bees. I don't like bees, but I like honey. My pa has a pig, a cow, and a calf. I have got two brothers and three sisters. I go to Sunday-school. If this is worth a book, send me one."

The above gives no new fact of general interest; and while it did very well at first, it sounds old now. Perhaps I am expecting a good deal from you little folks, but the last two or three issues of GLEANINGS proves that you *can* write real good letters if you try.

Now I am going to give you some work to do. While the bees are getting a little pol-

len, tell us, as well as you can, from what flowers the bees are gathering it, and its respective color; how they put it on to their legs, and how they take it off. One more, and then I'll stop. Mark a bee in some way that has lost his sting (perhaps you can cage him best), and tell us how long he lives, or whether he dies at all. I am aware these are hard; but if you get your mamma to help you, I think you can do it. Now if you will try to help me, I will give you a talk upon a bee's leg; won't that be a queer subject?

I'll sign myself— HUBER'S BROTHER.

ANOTHER HUBER.

My name is Huber. My brother Charlie has five hives of bees; he takes GLEANINGS. I think your Huber is as full of mischief as I ever was.

Geance, Ill.

HUBER ALLEN.

TWO BITS OF WAX.

My father has 15 hives of bees. This morning he was out, when a bee alighted on his hand, and he let the bee sit a while; and when the bee flew away he left two little bits of comb on pa's hand.

HENRY WILLIAMS.

Branks, Meade, Aug. 30, 1885.

A SWARM OF BEES THAT STAYED ON A CURRIANT BUSH ALL NIGHT.

We have 12 hives of bees, and I have a house in the garden, just beside the hives. Last summer I found a swarm of currant bush, that had been on the bush all night.

THERESA LINTON, age 7.

Amherst, Ohio.

BEE-POISON, AND HOW IT AFFECTS SOME PEOPLE.

My cousin has many hives of bees; he takes in honey every year. His name is Willie Blair. When the bees sting him it lays him in bed about a week; but when the bees sting us it does not harm us.

Stutebort, S. C.

GEORGE S. ELLISON, age 8.

A LITTLE GIRL WHOSE PA TOOK 650 LBS. OF HONEY.

My pa has lots of bees, all Italians. He sold 650 lbs. of honey last year. He has a foundation-mill, and I help him to make foundation. I love to help make it and put in section boxes.

Ellismound, Ill.

EMERY PEER, age 10.

JOHN'S LETTER: SOMETHING ABOUT WHITE-FACED CATTLE.

My uncle has eight hives of bees. They made 350 lbs. of honey. He went to Aurora, Ill., on Christmas, and bought six head of Hereford cattle. They all have white faces. They look very nice.

Mt. Carroll, Ill., Jan. 8, 1885.

JOHN ROHRER.

"PUT MY PAPA DOWN IN BLASTED HOPES."

Put my papa down in Blasted Hopes. Two years ago we had 100 swarms, and now he has just two left. My grandpa Bennett takes GLEANINGS, and I like to read the letters from the little boys and girls. I am going to save up my money until I get enough for grandpa to send for me a watch.

Alexandria, Minn.

TOMMY COWING, age 10.

HOW TO COLLECT INSECTS.

I am making a collection of butterflies and bugs. I have made one, and now I am making another. The way I make them, I take a box with a thin bottom, and drive pins up through, about one inch apart. When I get the butterflies and bugs I kill them, and put them on the pins, and it makes a real

pretty collection. My brother takes GLEANINGS, and I like to read the letters from little folks.

NETTIE H. CRANSTON, age 10.

Woodstock, Champaign Co., O., Sept. 19, 1885.

All right, friend Nettie; but whatever you do, don't be cruel to the poor butterflies and bugs. If it is necessary to kill them, do it with chloroform, or in some similar way, so as to avoid giving them pain, or torturing the poor things needlessly. Prof. Cook recently told us how he kills bugs and insects.

LIZZIE'S LETTER.

My little sister wrote you a letter to-day, and I thought I would try to write one; but I don't know how to word a letter. Papa told me to tell you that he had 156 stands of bees. He sold 31 stands for \$156, and he sold lots of Italian queens. I am a little girl, and can't do much but go to school and play.

LIZZIE PEER, age 7.

Ellismond, Ill.

SOMETHING FROM FLORIDA—FISH, OYSTERS, AND BEES.

We have lots of fish and oysters down here. I think that you had better come down here and get some. The bees have not done well this summer. We have three hives of bees; we got a small barrel of honey from our bees.

EVA S. GLAWSON.

Hawk's Park, Florida.

PUTTING BEES UP STAIRS FOR WINTER—RESULTS.

My father has 15 stands of bees. I have one stand. Father put one stand of bees up stairs to feed it, and it got too hot for them up there, and he brought it down and let them fly, and did not put it up again, and it starved to death. Another one died and he took out the honey and weighed it. It weighed about 40 lbs.

GEORGE E. GILSON, age 12.
Westchester, Ind.

HOW PAPA WINTERED A SWARM ABOVE THE COAL-STOVE.

My papa keeps a few bees. He commenced last spring with four colonies; increased to ten; we got only 61 lbs. of honey. Two colonies have died during the winter. My papa took one colony up stairs in a room above the coal-stove, to experiment, and darkened the room. They wintered very nicely, and he thinks it is a good way to winter bees.

Burlington, Pa. EDWIN E. MERRING, age 10.

DID OUR BEES DIE BECAUSE OF MOLDY COMES?

My brothers Jasper and Philip keep bees; they bought three hives of Italians last summer, and they had six swarms from them; they put them into the cellar after snow and frost had come. The comb got moldy. They had plenty of honey. They all died but two swarms. Do you think they died from the comb being moldy? My brother takes GLEANINGS. I like to read the little letters.

Hassan, Minn. GEORGE S. TUCKER.

A LITTLE GIRL WHOSE SISTERS HAVE EACH A STAND OF BEES, BUT NONE HERSELF.

I don't like honey very well, but I like to see the bees gather it. I have five sisters, and they have a stand of bees apiece, but I haven't any. Pa takes your journal. I like to get it and read it.

Glidden, Ia.

ZELLA EPPERT.

I think our papas ought to give each of the juveniles a swarm of bees by themselves. That would enkindle a new interest, and then what nice little letters we would have, all about bees! Mr. Hutchinson's little girls.

as he told you, have each a little swarm; and Blue Eyes, you know, had the biggest swarm in the apiary. When Huber gets big enough he shall have a swarm. Perhaps your papa is waiting till you get big enough too.

THREE HUNDRED STANDS OF BEES; A LITTLE GIRL WHO MAKES HERSELF USEFUL.

We have about 300 stands of bees. We haven't taken any honey since the last of July, as our honey-crop is poor this year. I helped pa with the bees, and liked it very well. He says he can't do without me in the honey-season. We have Plymouth Rock and Brahma chickens. Ma likes the Brahmas, and pa likes the Plymouth Rocks.

LALLA L. MARTIN, age 11.

Benton, Bossier Par., La., Sept. 24, 1885.

Well, Lalla, we have the Brahmas and Plymouth Rocks too, but I rather think I like the Brahmas better, so your mamma and I would agree on that point.

A PET FAWN.

Mr. Godkins, our neighbor, has a little deer. It is a year old. It wears a red ribbon with a bell on it. They caught it in the lumber-woods. He gave ten dollars for it, and he would not take fifty for it now. They feed it cookies, cake, pie, crackers, fried-cakes, bread and milk, and milk to drink. It is very tame; it comes to our house, over half a mile, and our dog scares it home. It is a grayish color.

JAMES W. RUSSELL, age 11.

Gilford, Mich.

A SWARM OF BEES FOUND UPON A WIRE FENCE: HOW THEY WERE HIVED AND WINTERED.

Two years ago my sister and I were gathering flowers, and we saw a swarm of bees on the wire fence. We went and told pa, and he got an old tea-box and put them in. They swarmed that summer, and pa put them into a chaff hive. We wintered them by turning a fifteen-bushel box down over the tea-box. They wintered well last winter. They have plenty of honey, and but few died. We had over 60 lbs. of surplus honey.

Radcliffe, Iowa. CLYDE WOODWARD, age 10.

BREAD AND HONEY, VERSUS SKATING.

I like to read the letters from the boys, so I thought I would write one. Papa keeps about 50 swarms of bees, and manufactures a chaff bee-hive, and sells a good many. He buys lots of things of you. We got about a ton of comb honey last year. My brother and I had one swarm which we owned together; but on account of the hard cold winter we lost them.

They are just finishing a roller skating-rink, about 60 rods from our house; but papa has bought his boys off by giving us a dollar apiece, so we are going to take the dollars and buy us some more bees; so when the rest are breaking their noses at the rink, we will eat bread and honey in the parlor.

CHARLIE B. HUMASON.

Vienna, Ohio.

Friend Charlie, your papa and I, I think, must be about of a mind. The effect of skating-rinks in our vicinity has been almost altogether bad, and I do think parents ought to try very hard to interest children in something at home—at least in places where they will not meet and be on a footing with the lowest and most depraved minds.

AN ESSAY ON BEES.

Bees are very industrious little insects. They gather honey every sunshiny day in the summer, and on cloudy days they make wax. They gather honey from clover-blossoms, and almost every kind of flowers. Bees will not sting if you do not molest them. Their color is brown and yellow. They are a little larger than the common house-fly. They kill all the drones when winter comes. I live in the western part of Iowa. Here the bees get honey from wild flowers, and I think from dogwood flowers. I should think bees would like columbine-blossoms.

MAY DREW.

Glidden, Ia.

Your essay is very good, friend May, but I am afraid it is not all of it altogether true. Bees do make wax on cloudy days, but I am not sure that they make it then more than they do on sunny days; and I am afraid it is not always true, that bees do not sting unless you molest them. It is a pretty good letter, though, for all that.

A JUVENILE SUPPLY-DEALER.

Mr. Daniel Howard came to pa's house, and stayed three or four months, and gave me one of your catalogues. I am a small boy; and as all boys like to have some pocket change, I spoke of sending to you for a few articles and selling them at a small profit, and, by so doing, turn my little mite over to advantage. My first attempt was rather discouraging; but your kindness reassured me.

My father is a planter on the Ouachita River. He owns 600 acres on the river, of as good land as is in the State. He owns a steam-gin and grist-mill. His steam-power is sufficient for a saw, and his uncultivated lands are covered with splendid timber. It is as healthy as any place in the South. He has three nice settlements on his land, and pa wishes to go north. If you see any one who wishes a cheap bargain in a healthy neighborhood, good schools, nice people, recommend them to pa. He will sell at very reasonable figures.

WILLIE RUSSELL.

Donaldson, Hot Spring Co., Ark., Sept. 14, 1885.

SOME KIND WORDS, AND FACTS OF GENERAL INTEREST.

My papa takes GLEANINGS, and likes it so well that when his six months is up he will take it all the time. We started in with six colonies, and this spring one was alive. We got two nice large swarms, and they have done well. We got 32 lbs. of nice white comb honey. We have 12 spider plants, to give the bees a trial, and they won't touch it. What is the reason? We can just see the little drops of nectar in each flower. Mr. Root, do you give smokers yet? If you do, please send my papa one. He has quit chewing and smoking. If he chews or smokes we will send you money for it. We like the way you talk in the A B C introduction. Papa says he thinks you are a Christian. We like that kind of God-fearing people. Brother and I both belong to the church. I will close, for fear you toss this into the waste-basket.

CLARENCE and HARRY BOONE, ages 11 and 9.

Shelbyville, Ills.

May God bless you, Clarence and Harry! and most gladly do we send your papa a smoker. What papa could break his pledge when two of his boys, aged nine and eleven, stand as vouchers for the faithful performance of his part of the contract?—The bees neglect your spider plants because they are

getting plenty of honey somewhere else. Am I not right about it, boys?

SOME KIND WORDS FROM A JUVENILE.

We all look for your paper, which comes regularly. Papa says he wonders how you do it. We are all sorry you lost your horse. We were pleased with your article about paying a fair price for what you buy. Pa read it all out for us, for people often call him foolish because he won't beat a man down when he asks a fair price for what he sells. I help papa with his bees. We lost none last winter. March, 1884, we began with four boxes. Now we have 15 hives. Papa is an engineer. He makes his own hives. We want him to succeed with his bees. He is not strong, and has bad health. We wish we could taste some of those apples, strawberries, and raspberries you write about. We can not grow any of them here. Papa planted lots of trees. None of us use tobacco, except my eldest brother; he thinks he looks like a man.

FREDERICK HAYLES, age 12.

Hondo City, Texas, Sept., 1885.

Why, Frederick, is it indeed true that you can not raise apples, strawberries, and raspberries, in Texas? Are you not mistaken about this? It seems to me I could make them grow wherever it is not too cold or too hot.

KIND WORDS FROM A LITTLE GIRL WHO DOES NOT FEEL THAT SHE IS A STRANGER.

I know I am a little stranger to you, but I don't feel as if you were one to me, because I have seen so many of your kind replies to little letters in GLEANINGS that it made me feel as if I wanted to hear from you too. My mamma says she thinks that you are a man with a great deal of patience to answer all the little letters from children. I don't know of any thing that I could tell you about bees that you don't already know, for I often ask my papa if he doesn't think that you know every thing about bees. My papa doesn't use tobacco in any form. There was a very serious case happened to a man who lived in our neighborhood who did use tobacco. He was going from the store, and a hard breeze came just as he was going through the gate, which slammed and drove the pipe-stem down his throat, and he nearly died before they could get him home, but I am glad to say that he is better. My papa has been keeping bees three years; he began with one hive of black bees in a box hive and one nucleus that he got from you. He now has nearly 50 hives of bees. I have a little book called "First Steps for Little Feet," and I have read it through now, and I think that it is just elegant.

Church Creek, Md. ELIZA R. BUSICK, age 8.

Thank you, Eliza, for your kind little letter. You need not be a stranger any longer, for I always feel at least some acquainted with every one who writes for GLEANINGS. A great many of the children are calling for the book you speak of—"First Steps for Little Feet," and I have just decided to buy a whole hundred dollar's worth at one time, so my little friends can all be supplied. The best thing about the little book is, that it teaches even the little feet to step toward heaven. Your sad story may not teach very much of a lesson against tobacco, but it does teach people to beware of going about with something sticking out of their mouth.

TOBACCO COLUMN.

WHAT A FRIEND CAN DO.

SINCE I have quit smoking myself, I have been trying to induce others to do so; and with your help I have succeeded in getting two, one of whom is Mr. Yandy, who has already received a smoker from you; the other is Mr. W. A. Smith. He wants a smoker also, and promises that if ever he uses tobacco again he will send you the price of the smoker. I can vouch for him myself, as he is a perfect gentleman.

Stanton, Ala.

C. W. PLANT.

You have struck the right way to strengthen yourself against tobacco -- go to doing missionary work among your friends. Why, it fairly makes my heart bound to think of the reformed tobacco-users working among their own friends, in the field where God has placed them, to get others to go and do likewise. Keep on in the good work, and God will help me to furnish all the smokers that may be needed to carry it on. Perhaps it may be well to add, that it will be well to keep a sort of brotherly watch over all these new converts, and see that they do not backslide. Let all the work be truthful, honest, and fair, or we can not, of course, expect God to bless us.

ONE WHO HAS BEEN A SLAVE FOR 22 YEARS, AND HOW HE GOT FREE.

I notice your offer to send any one who quits tobacco, a smoker. I used tobacco for 22 years, and was a regular slave to the use of the weed to such an extent it nearly prostrated my nervous system. On the first day of January, 1884, I resolved to quit for that day. That night I resolved to quit a week; at the end of a week I concluded to quit for all time. It is now nearly 20 months since I have used tobacco in any form. I am very much improved in general health; my pocket-book is much plumper, etc. I have never had any bees until this summer, and consequently had no use for a smoker. Should you send me one now, I will pledge you my word of honor, that should I ever begin the habit again, I will pay you in full the price of the same.

Carroll, Ind.

R. T. BARBER.

ONE WHO HAS USED TOBACCO 34 YEARS.

I have been using tobacco for thirty years, but have decided not to use it again. I have not used any for two years, and have no desire for it. I notice in GLEANINGS you give a smoker to those who quit. If you think me worthy of a smoker, send it; and if I commence to use it again I will send you one dollar to pay for the smoker.

Colfax, N. C.

JAMES A. GATES.

GOOD BAPTISTS CAN NOT USE TOBACCO.

Your card received, and contents noted. Upon your explanation, I can not claim the smoker, as your offer was not my motive. The reason I quit was, I am a Baptist; and good Baptists can not use tobacco.

O. P. STARK, M. D.

Valley Spring, Texas.

Why, God bless you, friend S., for putting it in that way. To be sure, it is not right for a Baptist to use tobacco; and if it were not for treading on somebody's toes, I should like to say that it does not seem to me as if a Methodist, or an Episcopalian, or a Disciple, or a Congregationalist, or any of the rest of them, can consistently use tobacco.

If any of these good brothers think I am carrying it too far, I would ask them to read the Scripture texts in our little book, entitled "A Dose of Truth." And, by the way, I will send this book free to any Christian of any denomination, who has been deliberating in his own mind whether he should or should not use tobacco.

I have given up the use of tobacco, and would like you to send me a smoker. I don't want to be paid for doing right, but it will help me to keep my pledge by having a smoker to pay for the first time I break said pledge.

REESE POWELL.

Mineral Point, Wis.

Why, Reese, is this you among the tobacco-converts? We did not know before that you used tobacco at all; but we are very glad to know that you have given it up. Our book-keepers have mentioned your name to me from time to time, and I have always told them that I was pretty sure you meant to be a good boy, and to do what is right. Since you have given up tobacco, I can feel still more confidence in putting in a plea for you whenever it shall be necessary.

IT SAVED ME DOLLARS.

Please receive my thanks for the good deed you did for me when you sent me the smoker, to stop the use of tobacco. It has saved me dollars, and I don't want smoking going on around me at all now. I will love you as long as I live to love anybody.

Sun Hill, Washington Co., Ga.

A. JOINER.

Why, friend J., you almost startle me. Is it really possible, that I have been gaining friends, and doing it, too, when I was not aware of it? Here again is an illustration of that little text, "Lord, when saw we thee a hungered, and fed thee? or thirsty, and gave thee drink?" etc. Remember, dear friend J., that I am only human, and sometimes I fear my friends think me most *sadly* human. You will probably be tried with me, sooner or later. Now, then, won't you just lay up a good store of charity while you feel like it, to be used when that time comes? And one more thing: If I did you a good service, will you not pass it right on to the next man, and get him to stop using tobacco in the way I induced you to stop? Whenever smokers are needed for the work, let me know, and I will furnish them -- providing, of course, the one who receives the smoker gives the usual promise, and is willing that his name should be published.

TWO LADIES WHO HAVE GIVEN UP TOBACCO.

As one of my lady friends has received a very pretty as well as useful present for giving up tobacco, I thought I was entitled to one for the same purpose. I quit using tobacco two years ago, and I never expect to renew the filthy habit. Having used it for many years I found it to be a very unnecessary habit.

SALLIE DAVIDSON.

Poca, West Virginia.

About two months ago I quit the use of tobacco, which I have used 12 years. Most of the time I chewed and smoked. I shall never use it any more. If you send me a smoker I will call it one more favor. In case I should ever use it again, I will send you pay for it.

J. O. MUNSON.

Peruville, N. Y.

OUR HOMES.

Charity thinketh no evil; hopeth all things; endureth all things.—1. COR. 13.

ARRIVING at my destination I climbed down from the locomotive (see page 708), and found I had over two hours to wait for the New-York train. I had had my dinner, as explained, and there was nothing to do; that is, I had no work planned for these two hours. Then came the question, What could I find to do that would be most profitable to myself and most profitable for you, dear readers? for I consider myself in one sense as your servant: for it was with the money that you have so freely furnished me that I had started on this errand. How could I benefit you most? The answer came, By educating myself in every possible way to minister to your wants and wishes. A saloon near at hand was doing a lively business, and was noisy with traffic; but I did not feel called there. In another direction was a wrench-factory, where busy wheels could be seen through the open windows, and I caught a glimpse of human beings also at work. I knew they made very nice goods there, for an adjustable wrench of their make is now on our 25-cent counter. Notwithstanding my experience with the engineer, mentioned in *Our Neighbors*, the old feeling of diffidence came up, and I didn't quite know whether they would want to be bothered with me or not, and I was thinking of going in one of the back doors around near the engine, and walking around without telling anybody who I was. Pretty soon I felt ashamed of myself, however, and mustered up courage enough to march right into the office. I handed my card to the book-keeper, telling him that I had two hours to wait, and that I should like to go over their neat-looking factory. Now it is an honest truth, dear friends, that I did not think of any further courtesy being shown to me, than that he would stop long enough to give me the asked-for permission. What did he do? Why, he opened the door and told me to come inside behind the railing. Then he told the partners who were present who I was, and they all rose up and shook me warmly by the hand, and expressed much surprise and pleasure to find that A. I. Root had really got away from home long enough to pay them a visit. One of the firm not only showed me all over the factory, and explained every thing to me in the kindest way, but he took me all over their little town, and showed me everything that I expressed an interest in. Thus the time passed very pleasantly until the train was nearly due.

While thinking of my want of charity for my fellow-men in that little transaction, I am reminded that quite a number of visitors have come to see us, and perhaps gone over our factory and grounds, and I did not know, until they were gone, that it was some friend with whom I had had deal, and whom I should have been very glad to meet. Like myself, they hesitated about bothering me, after I have said so much about being "exceedingly busy," "overworked," etc. Now

I will tell you how I feel about it. I am really glad to have visitors express a wish to see me; in fact, I would much rather that they would all come up into the office, and tell me who they are, and what they would like. Of course, it is oftentimes the case that some one of our clerks can wait on them better than I can. But I like to have them come up into the office, because then when I see them around I know who they are, and they know who I am. Why, I felt ever so much happier to be around with one of the proprietors, than if I had gone in the back way, not knowing whether I was wanted around there or not. Getting permission from the office is right and proper, when you go into any establishment; and if you want to look over an orchard, garden, or farm, *by all means* get permission to do so from the proprietor. It is well to be modest and humble, and perhaps a little backward about intruding; but one may carry this too far, and I am sure my tendency is almost always that way. I am apt to be lacking in that part of our text about hopefulness. A genuine Christian is not often an intruder, and he ought to have hopefulness enough to believe that people will be glad to see him, when he is away from home.

Mr. Holmes told me to get a seat in a palace car at once, and that the extra expense would be \$3.00 to New York. The conductor charged me \$3.50. Forgetting my lesson, I straightway made up my mind that he was one of that kind of conductors that we sometimes read about, who overcharge and put the remainder in their own pockets. He looked like a nice man, but this only set me to moralizing how little we can tell about a man by his looks. I thought I would not argue the case for a paltry half-dollar; but it began to sour me toward my fellow-men. Toward night he came and sat down by me, with some change in his hand. After a few pleasant remarks about the weather, etc., he extended the change, saying, "I owe you an apology, friend, for having taken a half-dollar too much from you, because I looked at the wrong column of figures."

Then I felt ashamed of myself again. "Thinketh no evil." Did that fit me? Not very well; and yet I make Christianity my theme. I shook off my uncharitable feelings, as it were, and asked him some questions about the way they manage to avoid mistakes, etc. He surprised me by very kindly and intelligently explaining the whole matter to me.

"Why, my dear sir, we *ought* to be correct and straight every time; and if we are not, we soon get *straightened*, I tell you. See here—I have punched the figures out of the check I gave you, representing the money received. This check goes to headquarters, with the holes all punched as you see, and there is no way in the world I can cover up this mistake. I have got to own it up, and make an explanation. See—I have made a ring around the place where I punched by mistake, to indicate at headquarters the blunder I made, and I feel a great deal more ashamed of it than I can tell you."

Now, this information has been worth a good deal to me. I didn't understand before why this system of checks and tickets, with punches for perforating them, was so much in use everywhere. It is for the purpose of making dishonesty almost impossible, providing the man who travels is intelligent enough to keep posted and understand it all. To make mistakes, whether intentional or unintentional, is almost impossible; that is, if the traveling public do their duty. And here I was *ignorant* and *uncharitable*. You see, I was learning lessons. We sometimes think the world is slow to receive lessons; but we generally think that we ourselves are bright and smart. In some respects I have a very good opinion indeed of myself. With these experiences that I have told you of, I ought to have had plenty of charity. Well, I guess I ought, but I didn't have, after all.

The first place I stopped at in the great city was at the office of the *American Grocer*, the publisher being brother of our short-hand writer who is taking down these notes. It was the same way. I felt diffident about intruding on his time, but I felt ashamed almost as soon as I met him. It was the same when I visited the great establishment of Thurber, Whyland & Co. I will tell you something about that visit in another place. After that I visited the large establishment where I buy the greater part of our counter goods. One of the clerks was somewhat acquainted by correspondence, because he made it his business to take charge of all our orders. Well, what kind of opinion do you suppose I had of him, without having ever seen him? To get at the truth which I want to inculcate to-day, I suppose I shall have to own up a good deal. Some way I had got it into my mind that most of the clerks in our great cities are of a drinking, swearing, theater-going class; that most of them would laugh at me, and call me a fanatic or religious enthusiast. Well, my reception by the clerks of this great establishment was a good deal like the rest I have been telling you about. They were quite overjoyed to see the man in New York who had a plain notice on one corner of his catalogue, saying that he gives away cards against profanity, to anybody who would take them. This brought out the fact that my friend was a Sunday-school worker — one who loved God, and hungered and thirsted after righteousness. You know we sell quite a number of books. Well, this establishment had a book department; that is, they sold a few select books. When they asked me to make a purchase of some books, and I ordered only a hundred *Pilgrim's Progress*, and no others, the clerks seemed a little surprised when I replied, "Boys, we sell only a limited number of books, and I have decided that these must be of such a character that I can carry them to the prisoners in our county jail to read, with a clear conscience."

Now, I did not think by this little speech that I was going to hurt anybody's feelings; but the clerk who made it a business to purchase their books made a start, and I could tell by his face and voice that he was hurt.

"Why, Mr. Root," said he, "are there any

books among our collections here that are in the least immoral in their tendencies?"

I assured him that I did not quite mean that; but the talk I had with him on the matter made me feel ashamed of myself again; and when these two young men, a little while later, introduced me to one of the partners, while their faces seemed to show they did it with considerable pride, I felt ashamed of myself again. One of them made a remark something like this:

"Mr. B., this is Mr. A. I. Root, who advertises printed cards against profanity, to give away; and at home where he lives he goes into the jail every Sunday and talks to the boys and men he finds there," etc.

I had a very pleasant talk with the proprietor; and while I was making my purchases, a clerk came to tell me that they wanted to see me in the office before I went away. When I went in there to see what was wanted, one of the firm came to me with a little bit of paper in his hand, and with a smile on his face, and said about as follows: "Mr. Root, I have had one of our book-keepers run up the amount of your purchases since you commenced to trade with us in 1880. Here it is on this bit of paper. We have sold you, in a little less than five years, \$4392.24. Now, that is a pretty fair amount to sell to one man in that length of time; but that is not the point just now, although we thank you for the trade you have given us. What I wanted to say for your encouragement is this: That, during these five years, we have never had to ask you for a cent of money, or hardly to send you a statement. Every bill has been paid promptly, within about ten days of its date."

"But," said I, "you gave a discount for prompt cash, and who would not pay under such circumstances?"

He replied, "Yes, I know we gave a discount; but I tell you, Mr. Root, the men who pay as promptly as you do, are not so plentiful but that when we find such a customer we want to keep him. Now, while I thank you, I want to say this: We know you buy largely in certain lines of goods; and we have learned by experience that we can safely give you close figures. We take no risk in getting our pay. Whenever you are in need of any article, whether we keep it or not, we will take pleasure in hunting it up for you, and in giving you prices that we could not give people whom we have found to be uncertain. Why, Mr. Root, you have no idea of how we are troubled and perplexed and bothered by men who make promises they do not keep or can not keep."

Now, dear friends, do not think I have told you all this because I want to boast of my good name in financial circles, but because I want to let you have the benefit of the moral. Has any one any adequate idea of the value of a good name? and are we working as we might work, even the best of us, to keep this good name free from blemish? It was another illustration to me of my want of charity. I didn't know that these people would be particularly glad to see me, and I had no conception of the estimation in which they held one who is

working for Christ. No matter what a man's religious belief is, he respects at once the one who loves God and his fellow-men.

You may think that my heart should have been enlarging a little by this time, and that these experiences should have taught me to have more faith in my fellow-men. Well, I believe I did begin to have a little better opinion of the world; but when I stepped into the great seed-house of Peter Henderson & Co., something of the same feeling came over me. In New York, space is so valuable that even large houses can not afford such roomy and airy offices as ours are here at the "Home of the Honey-Bees." In all these places I visited, every foot of space was economized, as if it were precious. A good deal of the ground in the city of New York, I have been told, is worth a thousand dollars a square foot. The offices were somewhat small where Mr. Henderson has his book-keepers, but somehow I felt a little backward about going in and interrupting so many busy people, especially when I didn't want any thing, so to speak. One of the clerks told me that Mr. Henderson was very busy, and he didn't know that Mr. H. would want to be interrupted. Perhaps I should remark, that it was Peter Henderson's son whom I found in the office that day. He was very busy with several people, and seemed greatly annoyed because some valuable paper was lost—so much so that I thought about going away without disturbing him. This wouldn't do, however, and so I mentioned my name, and told him where I came from. In an instant the troubled look on his face gave way to kindly looks. He gave up his paper, dismissed his friends, and with great kindness showed me from garret to cellar of that great seed-house. As I did not come to trade at this season of the year, I felt sorry to see him turn off other people whom I presumed must want something, so I did not stay very long at the store. I will tell you about my visit to the eight acres of greenhouses further along. I have spoken of the friends in New York who knew of me, and now I want to say a word in regard to utter strangers.

When I first came in sight of North River, at the terminus of our railroad, I was greatly astonished at the number of vessels, steamers, ferries, tugs, and many crafts that I could not tell the name of, and to see the way in which they crowded and rushed about in every direction, without smashing into each other. They seemed like mosquitoes dancing in the sunshine, only it was plainly evident there was no play about it. It was the busiest kind of business. Every craft was pushing for dear life toward some point ahead. Human beings were doing the same thing on the ferry-boat, although they did stand still until we neared the city wharf. Then out they poured into the streets. If I was astonished at the scene on the water, I was still more astonished at the streets of New York. Street-cars were chasing each other up one side of the street and down the other; carriages, carts, drays, milk-wagons, and all sorts of vehicles, were smashing ahead, crosswise, lengthwise, and turning and twisting. At almost every turn

it seemed to me that some vehicle narrowly escaped a smashup; but as these narrow escapes were before my eyes all the while, I was obliged to conclude that was the way they always did. Perhaps you have heard of the Irishman, who, when he first landed on our shores, was knocked down by a thunderbolt. When he got up, the first thing he asked was whether it did that way in America every day; for if it did, he thought he would get aboard the ship and go back straight home. This feeling kept coming up to me all the while, but I thought I would not go back home just yet. In addition to the annoyances and confusion on the pavements, the elevated railways overhead were continually scaring what little sense one had left, out of him. They, too, went down one side and up the other, chasing each other like children about the room. On some of the streets, four tracks ran side by side on these elevated street railways. I thought I was bright enough to take care of myself, and keep out of the way; but every little while somebody would kindly take me by the arm and pull me this way and then that way, to keep me out of danger. While I was looking out for one vehicle, some one from another direction would be right on to me. I expected somebody to swear at me, or call me a fool, because I kept continually getting into places of danger. But they didn't; on the contrary, I received the utmost kindness everywhere. The conductor took hold of me, and pulled me into the car, when a street-car running in the opposite direction was pretty close. Everybody answered questions so kindly and so fully that I could not but thank God while I thanked them. Policemen, conductors, clerks at the hotels, and everybody else, seemed to take it for granted that their business in life was to make it just as pleasant for such chaps as myself as they knew how to do, and it surprised me. Dear friends, I am really afraid it is true, that we in the country are much more given to surliness and short answers than our fellows in these great busy cities. I saw saloons, but I saw very little drunkenness. One thing that pleased me was to see the number of neat notices, even at the saloons, announcing "Ice-Cold Milk, only 3 cents a Glass." At some places, it read, "Orange-County Milk." Then the old uncharitable feeling suggested that it was not Orange-County milk, and that it was perhaps chalk and water that we read about in the papers. My friends, the milk was just as nice as that we get from our Jersey cow at home; and if one is short of means he can live very cheaply, even in this great busy booming city. I spent one evening there. I had forgotten to ask my friends where I could go in the evening, to a place fit for a Christian to go, and so I consulted the papers at the hotel. There were plenty of theaters, but, of course, that was not the place for me. So I thought I would study humanity on the streets. Well, I went miles on the street-cars and on foot, in different directions, and pushed my way into the crowds, but every thing was quiet and orderly. Why, it seemed to me like one great family circle. Children were playing

around under the light of the electric lamps, and on one street, where it was not very busy, a company of juveniles played "training-day," and a great crowd of ragged little ones, some no larger than Huber, followed a life and drum. But no one was hurt, and none were uncivil. I did not even hear bad words. One woman was arrested for drunkenness; and a great gaping crowd elbowed and tiptoed for a little time to see what the excitement was. The sight of her besotted face, however, soon satisfied them, as it did myself, and she was taken away in comparative quietness.

On Wall Street I saw the statue of the father of our country, and with uncovered head I stepped on the stone where he stood when he took the oath of allegiance. A little distance on, in Printing-House Square, I saw the statue of Benjamin Franklin.

With friend Root, of the *American Grocer*, I visited the New-York Postoffice, and had a glimpse behind the scenes. It does seem too bad that the clerks must do their work in a dusty and smoky atmosphere, lighted, even in the day time, by electric lights.

I crossed the great bridge that spans the East River, where the tallest-masted vessels sail under its immense arch, with plenty of room. It took us twenty minutes of fast walking to go across. Friend Root told me that it took fourteen years to build this great wonder, if not the greatest wonder, of the world; and for fourteen years he watched its progress as he went to and from his place of business. You pay one cent to go across on foot, or two cents to ride across, drawn by an endless cable and a cable that is always in motion. I told him, that in spite of all that has been said about seeing God through his works in the country, it seemed to me that God's finger was more plainly seen in the mighty works of the city than even in the country. He said he had often felt the same thing and agreed with me.

Now, then, comes pretty nearly my last visit, and most important to me of all—or, at least, the errand which called me to New York—the visit to Peter Henderson's greenhouses and grounds. The book-keeper at the seed-store gave me a pretty card, with full directions for reaching the greenhouses. This is a pleasant and convenient arrangement: for it indicates to any one who wishes to call, that they make a regular business of receiving visitors. The greenhouses were all that Henderson's catalogue represents them to be, and they do actually cover 8 acres. But I was a good deal disappointed to find that they are all used for raising flowers—nothing for vegetables and garden stuffs, unless it be one greenhouse for testing seeds. The grounds outdoors were also all devoted to raising flowers—nothing to gardening, unless it be one small piece devoted to strawberries and raising strawberry-plants, and a little patch of celery. Market gardens are all round about Henderson's grounds; but Peter Henderson, who has for so many years been looked upon as the most progressive market gardener of the world, is a market gardener no longer. I suppose flowers are more profitable. By the way, the only opportunity I had of seeing Peter

Henderson himself was at the rooms of the New-York Horticultural Institute, where a sale of orchids was going on. The young Mr. Henderson informed me that over \$10,000 worth of orchids was to be sold at auction, and that his father was very much interested in them. The display was weird and wonderful, and the strange blossoms made one feel queer to look at them. How did all this come about? and what purpose has Dame Nature in sporting in such strange, fantastic ways? While I stood there, a dried-up plant in a little bit of flower-pot was sold for \$100; and had anybody offered it to me I would not have carried it home for it. But, of course, all this was entirely out of my line. The study of these wonderful plants is certainly an innocent pastime, and we have no right to find fault with those who invest so much money in them, so long as the money is honestly their own, and they can afford it. I suppose if my wife and daughter had been with me as I passed through these great greenhouses they would have gone into ecstasies over the great beds of roses. They were pretty, of course; but the sight of a bed of lettuce that I saw a little later was worth ever so much more to me. In fact, one glimpse that I caught out of the street-car window, of a celery-plantation, was worth to me the whole trip to New York. There were about 15 acres in the lot. The rows were as straight as a line. Each celery-plant was so exactly like every other one, that there was practically no difference anywhere in the field of 15 acres. Every plant possessed that wonderful vivid green that indicates rank growth, such as we want in celery; and if there was a shriveled or wilted leaf in the whole field, I did not see it, although it was during quite a drought. The land on which it grew was valued at so high a figure that the owner informed me that he paid a yearly tax of \$100 an acre. He was a blunt, rough specimen of an English gardener, but a very successful one, so Henderson's people told me. When I first approached him he did not seem inclined to give me much attention, or to appear very civil. After I had talked with him a little, however, he dropped his work and jumped up with the alacrity of a schoolboy. Six large greenhouses were in process of construction, and nearly finished, solely for growing vegetables. When he found that I was deeply interested, and pretty well posted, he was exceedingly talkative, and told me some of his troubles, because some of the men wouldn't push his work along as his own trained gardeners were in the habit of doing things. He used a string of oaths while he talked with me, but seemed good-natured and friendly, even if he did. Time was too valuable for me, and probably for him, to enter into any discussion; but I made up my mind, that before I left I would try at least some gentle reproof. I made some suggestions in regard to his greenhouses, which were new to him, and he thanked me profusely, and begged me to call again to see how they worked when they got them filled with plants. I told him that I was quite sure they would work.

"Mr. Root," said he, "we are not really sure of any thing; they may work, and they may not. There are only two things in this world that are sure."

"And what are the two things that are absolutely sure, Mr. H.?"

"Death and taxes. They are sure to come to all of us."

"I agree with you, my friend. These two things *are* sure; and in view of the fact that there is no escape from them, does it not become us to be careful, *very* careful, that we are always ready to meet either?"

He gave me a quick look, as if he were not quite sure whether I was one of the pious kind or not, but I went on:

"Every good business man ought always to be ready to meet the payment of his taxes when they become due, ought he not?"

"Yes, sir, to be sure, he ought."

"Now, my good friend, you have been very kind to me this afternoon, and I thank you. I may never meet you again, and may never have the opportunity of repaying your kindness; but do, I beseech you, be as ready to meet death when God shall call us home, as you have been in life to meet the payment of every just debt. I have been told that you are a successful and responsible man. Don't forget this other thing besides taxes that must be met."

His countenance softened, and he looked as though he was touched.

"I know, I know," said he, "that we are not often as ready to meet death as the other; and I know, too, Mr. Root, that we ought to be."

I did not say a word about his swearing, but he understood it all the same; and I was sure, by the warmth with which he took my hand, that he was not at all displeased. He had no feeling that I had been preaching to him. As I passed away I gave another longing look at the lettuce-beds. Some of his men were transplanting some of the bright-green little plants. I noticed, that as soon as they put them out, a board shutter instead of a sash was placed over them to keep off the sun. Other men were packing the beautiful heads of lettuce in barrels. One of Mr. Hudson's neighbors (for that was his name) told me there was a spell during the past season when New York was almost destitute of lettuce. The demand became so great that Mr. H. sold almost his whole crop as high as six cents a head, and with the proceeds he got at least a part of the money to build these six green-houses, all to be heated by one boiler. There before my eyes was the sight I had gone clear to New York to see — plants growing with wonderful vigor, and that, too, right at the time when we here in Ohio, and over a great part of the United States, are letting every thing go to weeds and decay; and besides that, preparations for having this wonderful growth go on uninterruptedly all winter long. You may say, "Oh, yes! that will do very well for such a market as New York." But, my friends, I am inclined to think those beautiful heads of lettuce that Mr. Hudson's men were pulling and putting into barrels would sell in your town or mine for at least five cents a head, at almost any

time during the coming winter, and perhaps even now before winter has come.

T. B. TERRY'S TOOL-HOUSE.

SOMETHING ABOUT TAKING CARE OF TOOLS IN GENERAL.

THE friends will remember, that in our issue for Sept. 15 I gave a promise of having an engraving made, and here it is. When I first looked about friend Terry's premises, this tool-house was about the first thing that attracted my eye. One of the doors was open, so that I could get a glimpse inside, and I caught the idea at once. I was the better prepared to appreciate it, because I had a similar tool-house constructed about a year ago, only mine was a lean-to shed, put up against the east side of our largest warehouse, and in ours the doors were omitted. The consequence was, the only way to get a tool in was to back in, and everybody found it so handy that pretty soon it was a half-day's work to get a tool out or in, and so the boys dropped back into the fashion of leaving all the vehicles scattered around where they were used last.

I remember one day of, wanting some little implement for just a little while, and a neighbor's reaper was so placed that it must be pulled out in the mud, in order to get the tool. We didn't make the gravel bed inside of the house, that friend Terry speaks of in his account further along; and the consequence was, that when the ground became quite soft the heavy tools sank into the heavy clay soil, and after a while they froze fast. Besides, some of our more enterprising chickens decided that it was nicer, and more airy a place in which to roost, and therefore they took up their quarters right over some of our high-priced machinery. Do you wonder I got the blues sometimes, and almost wished I had never tried to be a farmer? Come to think of it, I do not know, but I almost wished I had never tried to be anything or anybody. I thought of doors, but I remembered former experience in baying doors slammed by the wind until they were repeatedly torn from their hinges. Somebody suggested sliding-doors; but I also remembered sundry times when I tried to move heavy sliding-doors when I was in a hurry, when they went so hard that it took so much of my small amount of strength that I had neither strength nor energy to do the work after I got my tools out into the field. Well, Mr. Terry agrees with me in regard to sliding-doors; at least, he said he did not like them. He did not say he did not like to have doors slamming; but the moment I saw that little iron hand-spike with the eye on top, and hinged to the door, I knew what it was for. The other end is sharpened to a blunt point, so as to stick into the ground; but lest it go into the ground too far when said ground is too soft, a washer is shrunk on, as he describes. Then when this little hand-spike is not to be used, instead of having it flacking about, it is lifted up and laid on a nice little strong hook, prepared for the purpose. The en-

graver has forgotten to show this little hook, or did not see it.

That buggy, of which you can see only the back end, is so neat and clean that it made one think of silk dresses and Sunday, almost instinctively. The buggy is large enough to hold friend Terry's whole family, or almost any whole family; but for all that, it is a one-horse buggy. I didn't have to wonder *who* the horse (if you will pardon the expression) was very long, for pretty soon we found Mr. Terry with two immense horses, either one of which would take that buggy anywhere, whether said family occupied it or not. The horses were hitched to what I should call an enormous great stout wagon. I looked at the wagon, and then I looked at the horses, and I concluded they were all in keeping with each other. Pretty soon it occurred to me that one of the queer things about friend Terry and his horses is, that he never feeds them any grain—simply hay, and nothing else (unless, as some of his neighbors say, it is not hay, it is just dried

window in the west end right end in picture) below, east end up stairs, and one in the back side in the stairway, so it gives light both above and below. The floor above, of matched flooring, covers all but the two west bents; these are open clear up to the roof, as I will explain further on. The room up stairs is very handy for storing odds and ends, and our little folks think it just an A 1 skating-rink.

We used 12-foot posts, and made roof $1\frac{1}{2}$ pitch. The door-fastenings, shown in picture, are very neat and cheap. I would call particular attention to the irons for keeping the doors open, which are shown on doors that are open. They are simple $\frac{3}{4}$ -inch iron rods, with an eye in the upper end, with a staple through it. At the lower end they are sharp, and a piece of iron one inch by two and $\frac{1}{4}$ thick is shrunk on to keep them from going into the ground too far. When not in use they are laid up in a little hook inside of door. They will save doors by keeping them from slamming, and you will never have to hunt for a stick when you are in a hurry. All doors are fastened on the inside but one, which has a latch and lock. The lower floor is of dirt, or

TOOL-HOUSE BELONGING TO T. B. TERRY, OF HUDSON, O.

grass). Mr. Terry does not dispute with them, for he has his own notions about how grass ought to be dried, and his notions seem to agree well with the notions of the horses, for they were as pretty a team of heavy work-horses as I think I have ever looked on. Well, perhaps I have said enough now, and so I will let Mr. Terry describe the tool-house himself. If I am not mistaken, there will be more tool-houses built like it, somewhere where GLEANINGS goes.

DESCRIPTION OF TOOL-HOUSE.

The entire front is composed of doors, so as to make it as easy as possible to get tools in and out. The building is boarded up and down with 12-inch barn-boards, and tightly battened. The doors are made of matched flooring. Each door-post is set on a large stone going down into the ground some 3 feet, and a one-inch iron dowel put in post and stone, so they can not get out of place. The rest of the building is underpinned tightly, except under the doors, of course. It has a neat cornice, water-conductors, and three coats of paint. There is a

gravel, raised just enough so water will never run in, but not enough so but that you can easily get any tool in or out. I like a dirt floor best, as it is so easy to get tools in or out. Six inches gentle rise, sloping back some ten feet, is ample. The first pair of doors to the left are nearly 12 feet wide, so they will take in a low-down twine-binder, horse-rake, etc.

The next four pairs of doors are nearly 8 feet each, and the west pair nearly 12 feet. Opposite the latter are two doors in the rear, so we can drive in a load of hay or grain temporarily, and drive right out the other side. Also, we can leave binder, manure-spreader, or mowing-machine in there over night, when in use (by putting wagons on barn floor, and not take time to put up in its place. For this reason no floor was put on over this end. The west doors are full height of building. The next pair are about half way between these and the others, as you will notice. They are for top carriages.

At the rear of this department is a cupboard for carriage harnesses, where they can be kept nice and clean. The building is 22×56, and will just hold

every tool, wagon, and carriage on the farm without crowding. The tools, etc., were measured, and the building built to fit—no waste room. It is intended to have it join a new bank barn on the west, when we are able to build the same, with a door through into horse-stable of barn, which will be on same level.

The cost of the building, all neatly finished, was \$400 in cash, besides what we could do ourselves, without interfering with farm work. To say that we enjoy it greatly, and think it is one of the best investments we ever made, is needless.

The contents of building below, beginning at west end, are—2 large wagons; 1 top carriage; 1 open buggy; 2 potato-diggers (new this year); 2 Acme harrows; 2 Oliver chilled plows; 1 subsoil plow, Minor; 1 Thomas harrow; 1 perfected pulverizer; 1 potato-planter; 4 one-horse cultivators and horse-hoes; 1 two-horse sulky cultivator; 1 seeder attachment; 1 Cahoon hand-seeder; 1 roller; 1 manure-spreader; 1 low-down Buckeye twine-binder; 1 Eureka mower, 6-foot cutter-bar; 1 one-horse dump hay-rake; 1 sled.

Up stairs are stored sleigh, 3 horse pole, side-boards, Victor potato-coverer, etc. It addition to the above is the usual supply of little tools, stored where they can be got at handily, and it is quite possible some large ones which I have overlooked.

Hudson, Ohio.

T. B. TERRY.

Well, I have something more from friend Terry yet; and as it concerns, indirectly at least, the tool-house we have been talking about, I think I will put it in right here. For a head to the letter, I think we will say:

LENDING TOOLS TO NEIGHBORS.

Friend Root: It seems I do not always make myself fully understood. I did not intend to say, or have you think, that I had no neighbors who would use tools carefully, and return them promptly, and do the fair thing about paying for their use. I said I did not think it would answer to lend expensive tools. A single illustration will perhaps explain my meaning. Years ago I was fitting a piece of land for Hungarian grass. A farmer came to borrow my roller to roll in his Hungarian seed. He promised to have it back here by the time I got my ground ready. It did not come, for he let a careless man drive it (just as he would have done his own, if he had owned one, doubtless), who drove across a dead furrow with a large load of stone on, and smashed it all down. He got it fixed as soon as possible, but it was too late for me to use it on my crop. You see the point: My neighbor's ground was rolled, while mine had to go without. I owned the roller, and he got the use of it. He offered to pay me, but it cost him so much to repair it that I was ashamed to charge any thing. The loss to me was a good many dollars. It seemed as though this was loving my neighbor (particularly when he was worth ten times as much as I) better than myself, and I put my foot down then and there that I would not in the future make a business of lending expensive tools—or borrowing either. Any simple tool like a fork, or even a plow, I always gladly lend to any one in need; and if a neighbor should have the bad luck to break some expensive tool when the loss of its use would be a serious damage to him, I would lend him any thing, even if I had to go with it to help him out. But when men pretend to be farmers, and make a business of borrowing tools that every farmer ought to have, it does not hurt

my conscience any to tell them plainly that I can not afford to lend to them. Such men are the ones who are careless of tools, and slow to return them. A young farmer just starting for himself, and unable to buy, would stand a very good chance to get what he wanted of me, gratis, until he could go alone. Still, it makes trouble to lend to one and not to another. I should like to please all; but I must look to my own interests also, and good tools in good order and ready at a moment's notice are necessary to success on the farm.

There, friend Root, am I not about sound on the lending question? At any rate, these are about my views; but if you can show me wherein they are wrong I will try to change.

T. B. TERRY.

Hudson, Ohio, Sept. 24, 1885.

Thank you, friend T., for your explanation, and forgive me if I seemed to criticise a little. If I did, I meant to include myself in the criticism: for after the conversation referred to was over, I had a sort of guilty feeling for the part I had taken in it; that is, we three all had been talking and telling stories in a way that seemed to reflect on our neighbors; and if it is hard to get along with neighbors sometimes, God only knows where we should be if it were not for these same neighbors. I think you are sound, friend T., on the lending question; but let us beware of falling into not only uncharitable talk but uncharitable feelings toward these same God-given neighbors, shall we not?

GLEANINGS IN BEE CULTURE.

EDITOR AND PUBLISHER

MEDINA, O.

TERMS: \$1.00 PER YEAR, POSTPAID.

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, OCT. 13, 1885.

Blessed is the man that walketh not in the counsel of the ungodly, nor standeth in the way of sinners, nor sitteth in the seat of the scornful. Psalm 1.

REMEMBER, 5 per cent discount on all goods ordered now for next season's use.

HEDDON'S EXTRACTED HONEY.

The two kegs mentioned in a previous number came to hand in good order. Not a drop of honey had escaped to make things dauby. The quality of the honey is certainly superior. Our stenographer describes it exactly by saying that there is a "finish" to the flavor that we do not often find in ordinary brands.

MIXING ORDERS IN WITH "VISITING" LETTERS.

If you want your orders to be filled by first mail or first train, don't put them in the middle of a long letter. Our long letters are frequently laid aside until we can get time to go through them carefully, while every thing in the shape of an order is pushed ahead to the proper clerk the minute our eyes rest upon it. You need not put the orders in a separate piece of paper unless you choose, but please let them come first. If they are to be made conditional, mark them so, and say, "See particulars below."

CONCORD GRAPEVINES, AND BASSWOOD AND TULIP TREES FOR FALL PLANTING.

Now is the time to put them out, and we have a better stock of better trees and vines than we ever had before. The grapevines were put out on our grounds just about a year ago, and have made a splendid growth during the past season, under the influence of underdraining, subsoiling, and good cultivation. Price 10 cts. each; 85 cts. for 10, or \$6.50 per 100. If sent by mail, 5 cts. each extra for postage and packing. The postage is a little more than former years, as the vines are larger and better rooted. For prices of basswood and tulip trees, see our price list.

FOUNDATION WITH HIGH WALLS FOR SHALLOW WALLS; WHICH IS PREFERABLE?

OUR friends are probably aware, that for several years samples of comb foundation have been sent out having walls so deep that it is really a pretty near approach to honey-comb itself. The queen might lay eggs in this foundation, or the bees might store a little honey in it, without any working-over at all. Of course, the walls are much thicker than the walls of natural comb, or the walls built on foundation having only a shallow wall when given to the bees. Now the point is, do the bees make these walls thinner, and do they take hold of this high-wall foundation quicker than that made with shallow walls? To test the matter we have recently placed pieces of both kinds of foundation side by side, attached to the comb-guide of an empty frame, and placed the same in the center of strong colonies. The result is this: The bees take hold of one kind of foundation just as quick as the other, and they draw it out into comb at the same rate of speed—we can not see a bit of difference. But when the finished comb is held up to the light, there is a very remarkable difference. The deep-cell heavy foundation has the bottom just about as it was made by the foundation-rolls. The deep walls are also about the same, while the other is thinned down in both wall and base of cell, so near to that of natural comb that it is difficult to distinguish the difference. The friends may be perhaps aware, that the foundation we have sent out has always been with rather shallow walls—walls not too deep for the bee to grasp with his mandibles, and fashion over to suit his notion. With our foundation, we give on an average about 7 sq. ft. to the pound, for brood-combs. The deep heavy-wall foundation, such as several manufacturers send out, give us from 4 to 6 feet to the pound. We have seen some specimens so heavy that 3½ sq. ft. would make a pound. Now, then, we can easily figure how much more it costs; and I think if you will make the experiment as we have done, you will find your wax is pretty much all right where the mill put it, after the bees have drawn it out into comb. The deep-wall foundation is handsome to look at, I am well aware; but I can not discover that it has any other merit, and it is terribly expensive, if we have made no mistake in our experiments. Of course, the above refers to brood-combs only. If you use heavy foundation for surplus boxes, you will have the "fish-bone" that has been complained of, without any doubt.

FOR SALE,

A SECOND-HAND TWO-HORSE-POWER EUREKA ENGINE AND BOILER.

The above engine has been in use about five years; but Mr. A. F. Stauffer, of Sterling, Ill., of whom we purchased it, writes in regard to it as follows:

I guarantee the engine to be in good working shape, as good as it ever was. I had boiler examined last spring by a steam-fitter, and he pronounced it as good as new. I always used soft water. I am furnishing my shop with new machinery and am anxious to sell or exchange it. I have to get more machinery, and my two-horse power is too light.

Sterling, Ill.

A. F. STAUFFER.

We will sell the above engine, to be taken at Sterling, Ill., for an even \$100, and we will put our guarantee on top of that of friend S. We obtained it of him in exchange for some new machinery, he, of course, putting in a larger engine and boiler.

Also one second-hand **Pony Planer** for sale. This planer is one that we used in our factory for planing all our basswood plank, heavy lumber, etc., and was set aside only because of the increase of our business. The plane is 24 inches in width, and such a machine would cost new \$140 net cash. It is all in good trim, and ready for work, with an extra pair of new knives, and it will be sold for just half price, or \$70.00.

A. I. ROOT, Medina, Ohio.

* FOR SALE *

I WILL SELL

Full Swarms of Pure Italian Bees

DURING THIS MONTH FOR

Four Dollars Each.

They are in 10-frame Simplicity hives, and in good winter shape. Ready to ship now. Send money by registered letter. Address

SALE AND RETAIL.** See advertisement in another column. 3btf

HONEY AND BEESWAX.

We are now in the market, and will be during the entire season, for all honey offered us, in any quantity, shape, or condition, just so it is pure. We will sell on commission, charging 5 per cent; or if a sample is sent us, we will make the best cash offer the general market will afford. We will handle beeswax the same way, and can furnish bee-men in quantities, crude or refined, at lowest market prices. Our junior member in this department, Mr. Jerome Twiehell, has full charge, which insures prompt and careful attention in all its details.

Sample of comb honey must be a full case, representing a fair average of the lot. On such sample we will make prompt returns, whether we buy or not.

CLEMONS, CLOON & CO.,

Kansas City, Mo.

TRY THE BELLINZONA ITALIANS,

15tdfb

And see for yourself that they are the best. Warranted Queens, bred from mothers imported direct from the mountains of Italy, \$1.00 each; 6 for \$5.00. Special discount on large orders. Satisfaction guaranteed. Send for circular. Orders filled promptly.

CHAS. D. DUVALL,

SPENCERVILLE, MONT. CO., MD.

Wanted. To buy a small farm and apiary. Give terms of sale, honey resources, distance to school and church. California given preference.

E. S. ARWINE,

Patterson, Waller Co., Texas.

For Christmas. 50 SCROLL-SAW DESIGNS for working brackets, easels, etc., 10c. J. L. HYDE, POMFRET LANDING, CONN. 1914b

Names of responsible parties will be inserted in any of the following departments, at a uniform price of 20 cents each insertion, or \$2.00 per year.

\$1.00 Queens.

Names inserted in this department the first time without charge. After, 20c each insertion, or \$2.00 per year.

Those whose names appear below agree to furnish Italian queens for \$1.00 each, under the following conditions: No guarantee is to be assumed of purity, or anything of the kind, only that the queen be reared from a choice, pure mother, and had commenced to lay when they were shipped. They also agree to return the money at any time when customers become impatient of such delays as may be unavoidable.

Bear in mind, that he who sends the best queens, put up most neatly and most securely, will probably receive the most orders. Special rates for warranted and tested queens, furnished on application to any of the parties. Names with * use an imported queen-mother. If the queen arrives dead, notify us and we will send you another. Probably none will be sent for \$1.00 before July 1st, or after Nov. If wanted sooner, or later, see rates in price list.

JOB LOT OF WIRE CLOTH

AT GREATLY REDUCED PRICES.

SECOND QUALITY WIRE CLOTH AT 1 1/2 CTS. PER SQUARE FT.

SOME OF THE SIZES TO WHICH THIS WIRE CLOTH CAN BE ADAPTED.

This wire cloth is second quality. It will answer needs for covering doors and windows, to keep out flies and covering bee hives and cages for shipping bees, making frames for sifting seeds, etc.

Inches Wide.	No. of Rolls.	Number of Squares of wire in each Roll.	Respectively.
10	3 3/4 rolls of 25, 72 s. f.		
12	2 2/3 rolls, 109 s. f. each.		
20	3 3/4 rolls of 166 s. f. each.		
22	4 2/3 rolls of 181, 1 of 169 s. f.		
24	6 4/5 rolls of 180, 1 of 182, and 1 of 190 s. f.		
26	23 rolls of 217, 28 of 216, 7 of 195, 1 of 193, 1 of 191, 1 of 187, 1 of 183, 1 of 210 s. f.		
28	16 1/3 rolls of 233, and 2 of 231 s. f.		
34	7 5/8 rolls of 281 s. f.		
36			
38	28 rolls of 316, 3 of 285, 2 of 317, 1 each of 190, 622, 197 and 215 s. f.		
42	1 roll of 348 s. f.		
44	2 1/2 rolls of 366, 1 of 348 s. f.		
46	1 roll of 152 s. f.		
48	12 9/10 rolls of 400, 1 of 100, 1 of 30, 1 of 200 s. f.		

FIRST QUALITY WIRE CLOTH AT 1 1/2 CTS. PER SQUARE FT.

The following is first quality, and is worth 1 1/2 cts. per square foot. It can be used for any purpose for which wire cloth is ordinarily used; and even at 1 1/2 cts. per sq. ft. it is far below the prices usually charged at hardware and furnishing stores, as you will ascertain by making inquiry. We were able to secure this very low price by buying a quantity of over one thousand dollars' worth.

Inches Wide.	No. of Rolls.	Number of Squares of wire in each Roll.	Respectively.
10	1 roll of 156 s. f.		
12	22 roll each of 88, 143, 92 s. f.		
24	43 rolls of 200 sq. ft. each; 1 each of 50, 96, 120, 168, 100, 160, 150, 140 sq. ft.		
36	58 rolls of 216 sq. ft. each. 1 each of 195, 193, 300, 390, 361, 227, 201, 284 sq. ft.		
48	76 rolls of 233, 6 of 231, 3 of 219, 8 of 222, 7 of 224, 2 of 210, 1 of 117 sq. ft., 1 each of 39, 210, 257, 240, 215, 10, 92, 87 sq. ft.		
60	36 rolls of 250 sq. ft.; 1 each of 22, 137, 114, 117, 129, 125, 229, 225, 227, 237, 235, 275, 240, 137 sq. ft.		
72	12 of 266, 7 of 256, 2 of 253 square ft.; 1 each of 233, 254, 117 sq. ft.		
84	31 rolls of 283 sq. ft. each; 1 each of 62, 113, 198 sq. ft.		
96	22 rolls of 300 s. f. each; 2 of 71, 1 each of 285, 190, 279, 285 sq. ft.		
108	38 1/2 roll each of 300 and 316 sq. ft.		
120	40 1 roll of 233 square feet.		
144	42 1 roll of 350 square feet.		
168	46 1 roll of 192 square feet.

HONEY COLUMN.

CITY MARKETS.

KANSAS CITY.—*Honey.*—Demand for all kinds of honey good, and prices much improved. Choice 1-lb. sections bring 16¢ to 17¢ on arrival, and demand in excess of receipts. Ship now while the weather will admit and it will come in good shape and bring good prices. Two-pound sections are sold nearly altogether now from California stock, being cheaper than any other, 12¢ to 14¢ being ruling rates for it. Extracted in fair demand at 40¢ to 45¢ dark, and 46¢ to 48¢ for light. *Beeswax.*—A little firmer, at 23¢ for good average stock. **CLEMONS, CLOON & CO.,**
Oct. 27, 1885. Cor. 4th & Walnut St's, K. C., Mo.

NEW YORK.—*Honey.*—The market is very active in comb honey. There is a good demand for all grades. Prices are ruling low. Fancy white 1-lb. sec., 14¢ to 16¢; 2-lb. sec., 12¢ to 13¢. Lower grades, 10¢ to 12¢. Bulk, 9¢ to 10¢. There is hardly any demand whatever for extracted honey. *Beeswax.* 25¢ to 26¢.
Oct. 12. **THURBER, WHYLAND & CO.,**
Reade & Hudson Sts. New York.

BOSTON.—*Honey.*—Honey is selling very well, but prices are very low, and we are often obliged to shade our price in order to make sales. We quote best 1-lb. sections, 14¢ to 16¢; and 2-lb. sections, 12¢ to 14¢. Extracted, 60¢ to 80¢. *Beeswax.* 30¢.
Oct. 22. **BLAKE & RIPLEY,**
57 Chatham St., Boston, Mass.

MILWAUKEE.—*Honey.*—This market continues about the same for honey as during the past month. The receipts are not large, and demand for comb is yet is rather moderate, while extracted is in good demand, and very little time before arrivals are sold. Comb, choice 1-lb. section, 16¢ to 18¢. Extracted, kegs and bbls., 8¢. **A. V. BISHOP,**
Oct. 23, 1885. 142 W. Water St., Milwaukee, Wis.

CHICAGO.—*Honey.*—Market is very firm. White comb brings 15¢ to 16¢, soon after arrival, the demand being equal to the receipts. Producers should forward their comb honey before freezing weather, so that it may get to market in good shape. There is no charge for storage. Extracted honey sells more freely at 50¢ to 55¢, according to quality.
Beeswax. 25¢ per pound for yellow.
Oct. 21, 1885. **R. A. BERNETT,**
161 So. Water St., Chicago, Ill.

ST. LOUIS.—*Honey.*—Extracted honey in bbls., Southern, 40¢ to 45¢. Northern, worth more; 2-eal. cans, retail, 85¢ to 1.00. Northern, 1-gallon cans, retail, 1.00. Comb honey—Our market is bare of choice white-clover—wanted at 17¢ to 18¢. Fancy, 20¢. *Beeswax.* 24¢ to 25¢. Fair demand, numerous inquiries.
W. T. ANDERSON & CO.,
Oct. 22, 1885. 104 N. Third St., St. Louis, Mo.

CLEVELAND.—*Honey.*—There has been a marked improvement in the demand for choice new honey within the past two weeks, and all receipts have been closed out at 14¢ to 15¢. There is a small stock of old on hand, which moves very slowly at 10¢ to 12¢. Extracted, 60¢ to 80¢. *Beeswax.* scarce at 22¢ to 25¢.
Oct. 21, 1885. **A. C. KENDEL,**
115 Ontario St., Cleveland, O.

FOR SALE.—500 lbs. ext'd white-clover and basswood honey in 15-lb. 10-gallon kegs at 75¢ per lb. Kegs thrown in free of charge.
M. ISBELL, Norwich, N. Y.

FOR SALE.—1500 lbs. of white-clover and linn extracted honey, put up in new oak kegs, of 15 lbs. each, delivered on board cars here for 80¢ per lb.
F. W. HOLMES, Coopersville, Mich.

FOR SALE.—10,000 lbs. of clover and basswood honey, fine quality, in barrels of 250 lbs. net, on cars here, for 80¢ per lb., including barrels.
E. FRANCE & SON, Plattville, Wis.

FOR SALE.—10,000 lbs. extracted honey, put up in 75-pound new tin cans, well crated, at 75¢ per pound, linn and white clover mixed. Warranted to be of best quality.
Address J. B. MURRAY, Ada, Ohio.

FOR SALE.—1500 lbs. extracted poplar and sumac honey in any kind of vessel, from 10 oz. tumbler up to 100-lb. tin cans, to the highest bidder.
H. M. MOYER, Hill Church, Berks Co., Pa.

WANTED.—1300 or 2000 lbs. of nice white comb honey in 1-lb. boxes; must be cheap—Ohio honey preferred. Address, stating price,
B. T. BLEASDALE, 556 Woodland Ave., Cleveland, O.

WANTED.—500 lbs. comb honey at Chicago prices, cash. **OLIVER FOSTER,** Mt. Vernon, Linn Co., Ia.

Recent Additions to the Counter Store. FIVE - CENT COUNTER.

Postage. {Pr. of 10, of 100

2 **POCKET SCISSORS**, round points, | 40 | 3 50
Solid-steel handle and blades, and only five cents. The secret of the wonderfully low price on these scissors is, that the inventor and manufacturer failed, and these goods were sold for what they would bring. As they are made of steel wire, they may not be considered handsome, but they are excellent for cutting, for all that.

2 **LAMP-BURNERS**, VENUS | 48 | 4 75
Two sizes, No. 9, and No. 1. I believe this is the first time that a good lamp-burner has been sold for the small sum of five cents, and we consider the Venus burner the best in the market.

FIFTY-CENT COUNTER.

10 **BUNYAN'S PILGRIM'S PROGRESS** | 3 50 | 32 50
A book of 32 pages, nicely bound and illustrated. Two copies, 50 cents; three copies, \$1.20; five copies or more, 35 cents each.

SEVENTY-FIVE CENT COUNTER.

SPADES FOR UNDERDRAINING | 6 00 | 55 00
Two kinds; one for ditching, the other for cleaning the bottom of the drain, and either kind is furnished with short or long handles, as may be preferred. They are of the finest quality of tempered steel, and are of the latest and most approved pattern.
A. I. ROOT, MEDINA, OHIO.

NOTES FROM THE BANNER APIARY.

NO. 21.

THE NORTH AMERICAN CONVENTION.

I WENT to Detroit last week to meet Mr. Cutting, and complete the arrangements for the coming meeting of the North American Bee-Keepers' Association. We worked hard to find some public building that could be had free of charge, but it was simply impossible. None of the city churches were ever used for such purposes, and it seemed for awhile as though we should be obliged to pay \$90 for the use of a hall. At last, however, we found a hall called the "Red Men's Wigwam," in which an organization called the "Red Men" hold their meetings. This hall will comfortably seat about 250 people, is well lighted, carpeted, furnished, and neat and cosy, and was secured for \$40.00. It is located at 63 Michigan Avenue, one block west of the City Hall, and just across the street from the Antisdel Hotel, which will be the hotel at which the society will make their headquarters. The regular rates are \$2.00 per day, but they have given us rates at \$1.25 per day, provided we will "double up" on rooms, and who ever knew a bee-keeper at a convention who wanted to be put off into a room all alone?

We called upon Mr. G. E. King, Secretary of the Mich. Railway Association, and we will have reduced rates in Michigan, and he said there would be no doubt but that he could secure reduced rates as far east as Buffalo, as far west as Chicago, and as far south as Toledo. I am now in correspondence with the secretaries of other associations, and expect to have reduced rates to still further points.

As soon as the arrangements are all completed I will make the announcements in all the bee-papers, and then all who intend to come can send for certificates.

I am working hard to get up a good programme. It is not yet complete, but I can announce the following: Reversing Combs, James Heddon; Bee Pasturage, Thomas G. Newman; Marketing Honey, C. F. Muth; Production of Extracted Honey, Chas. Dadant and Son; Production of Comb Honey, G. M. Doolittle; The Pollen Theory, Prof. A. J. Cook; Selling and Shipping Bees by the Pound, E. M. Hayhurst; Comb Foundation, John Vandervort; Wintering Bees, Ira Barber; Excellence or Cheapness, which? A. I. Root. There are several others to whom I have written, asking if they would lead in the discussion upon certain subjects, and I have not yet heard from them; hence I am not at liberty to make any more announcements.

Father Langstroth writes that he hopes to be with us, yet he is not certain. E. J. Outman will be present, also Wm. F. Clarke, Allen Pringle, H. R. Boardman, Dr. L. C. Whiting, H. D. Cutting, Dr. A. B. Mason, O. J. Hetherington, and James Ure. I have written to Mr. D. A. Jones, asking him to take the lead in the discussion upon the "Different Races of Bees." I have also written to a large number, asking them if they will be present; but their answers are only beginning to arrive.

The President of the Mich. Agricultural College, Mr. Willits, will be present, and welcome the society to Michigan. It will be remembered that he is the one who helped Prof. Cook to get the ruling that allows us to send our queens by mail. He will give us a "rouser." I have met him, and I know that he is capable of it.

The evening sessions will be devoted to answering questions. There will be a question-box, and all questions that come up during the day will be written out and dropped into the box, and at the evening session they will be taken out and discussed. Any one who will not be present can send questions to me at any time previous to or during the meeting, and I will put them into the box. If any questions are sent to me during the meeting, send them to Detroit, care of Antisdel House. The present indications are that the coming meeting will be one of the most pleasant, interesting, and successful ever held by the society, and I sincerely hope that as many of you as possible may be present to participate in the "good time."

S—W. Z. HUTCHINSON, 70—40.

Rogersville, Mich.

Sec. N. A. B. K. A.

Friend H., I want to encourage you in having done at least one good thing in this matter; that is, in choosing a hall that we have to pay for. If the bee-keepers of North America can't raise \$40.00 for the use of a hall, they are a rather sorry set. I am glad, too, that we are to be entertained at a hotel that does not have any whisky-shop just over t'other side, or back of the desk. The doubling-up won't hurt us in the least.

HOW TO RAISE BUCKWHEAT.

ITS SOIL, PREPARATION, AND HOW TO HARVEST.

I SEE considerable in GLEANINGS in regard to buckwheat for bee pasture. The main object of buckwheat is to secure a good crop of grain; for if you do this you will secure your crop of honey also. Now to do this there are several things to be considered; to wit, the quality of soil, the preparation, time of sowing, etc. Buckwheat will not pay in all localities in this country. Neither river bottoms, nor a loose rocky soil is good for it. On this account it produces such a luxuriant growth of straw that it falls down and does not fill; and the fog along rivers is thought to prevent its filling. As a rule it will not do well on a loose stubble-field, although I have known some good crops raised on wheat-stubble by breaking up and harrowing down level, then sowing and harrowing in.

To insure a good crop, select a good sod on a good clay soil that does not lie too level, so that it will drain well; break early in the season—the earlier the better; let it lie until near the time to sow, then cross the ground, stirring it well, and then let it lie a few days.

Harrow it down level, and sow broadcast, 3 pecks per acre, and harrow again, being careful to have the land perfectly dry when worked; for to work land when wet, for buckwheat, is to destroy the crop. The sod may be broken when moist, but not too wet. After this you may just as well not sow at all as to work the land when wet. The time for sowing here is from the 15th of June to the 10th of July; but if the locality is inclined to be frosty, I would not risk it later than the 1st of July. If your land is prepared as above, and sowed in time, if the land is strong enough to produce a good sod you will get a good crop without using fertilizers; but if it is not, a light top dressing of stable manure spread on and harrowed in with the buckwheat will pro-

duce a good crop. If you put it on too thick it will cause it to fall down. Lime is a good fertilizer, and also a good phosphate.

Now a few words in regard to harvesting: Cut when three-fourths of the grains are ripe; cut, if possible, when damp; let it lie in swaths a few days until the straw is partially cured, then rake in good-sized bunches, and set it up, twisting the tops, and then chuck it down well so that it will not fall down. If it does, it will not dry out; and if it should blow down it should be set up at once. Let it stand until dry, which will take from 8 to 12 days, if the weather is fine. If you have only a few acres, the cheapest way to thrash it is the old way with the flail, providing you or some of your neighbors have a fanning-mill. If it is as dry as it should be, two men will thrash as fast as one can haul, even if you have your floor prepared in the field where it grows. This is done by shoveling off the loose dirt until you come to solid ground, and let it dry off; you can then thrash with but little loss. If, however, you have a large crop you want the separator; and if you have a good barn floor, there is where you want to thrash. The best plan, after raising a crop of buckwheat, is to sow the stubble in oats and grass the following spring, so as to get back to a sod. It may be sown down in rye and grass the same fall, with good results.

WM. D. TITCHENELL.

Pleasant Hill, W. Va., Oct. 21, 1885.

Thanks, friend T. I believe I should agree with you in regard to buckwheat, only on our clay land we never have any success without phosphate, which we sow with a seed-drill, just as they sow it for wheat. In our locality it seems to fill better if sown rather late—just so as to escape frost, for instance. Our boys are just now thrashing an excellent crop that was sown about the first of August. We drill it in just as we drill in wheat.

OUR OWN APIARY.

AN IMPORTATION OF 75 QUEENS.

WE have just received another importation of 75 queens. They were shipped the 28th of Sept., and arrived here the 17th of Oct. There were only three dead and two missing out of the whole lot, and the rest are all safely introduced. Of all the importations of queens we have ever received, I think I never saw any equal to these. They are large and yellow, and at this date (Oct. 23d), are laying nicely. Including the imported queens we already had on hand, we now go into winter quarters with about a hundred, all told. This will give us a fine vigorous stock for next season. Taking every thing into consideration, the imported stock, season after season, seems to give the best results.

BEE-VEILS WITH GLASS FRONTS.

Several have sent us veils with glass fronts. We have given them a careful test; and while they are superior for a short time to any thing else for looking at eggs, we find them objectionable on account of the steam from the breath forming on the glass so soon. If the weather is at all cold, the glass becomes coated like the windows of a room on a frosty morning. Even in a warm day some moisture will collect upon the glass. Again, it is liable to be bro-

ken at any time, nor can it be carried in the pocket. A veil made of grenadine, with a Brussels net for the face, offers scarcely any obstruction to the eyesight. I don't remember that I ever had any trouble in seeing eggs with a veil of this kind. Unless the bees are very cross, or one has some particular work on hand, I think the ability to control the nerves and muscles of the face is far superior to any veil that was ever invented. One must have such control of himself, that when a bee alights upon his eye or nose, with evident hostile intent, he will pay no heed to it. In the great majority of cases, the bee will conclude that it is a waste of sting to give vent to his ire, when seemingly it would do no good. It took me a long time to learn this, and sometimes I got out of practice now. Father used to poke fun at me, and tell me that I would abandon the continual use of the veil. I mentally vowed I wouldn't; but it is strange how people *will* change their minds; isn't it, and that they should sometimes think that the sole embodiment of wisdom and experience is theirs?

THAT NAMELESS DISEASE, AGAIN?

A correspondent, in another column, claims that the removal of the queen does not effect a cure. Perhaps there are different phases of this disease, as of foul brood. The colony in our apiary that I spoke of some time ago seems to be on the road to recovery. The bees from the new queen we introduced seemed strong and healthy, and show none of the symptoms of the old bees. I am inclined to think that the disease that affected the swarm in our apiary is hereditary, though it may differ in other localities.

PAINTING HIVES.

We are now giving all our tin-roof chaff-hive covers a new coat of paint, as they begin to need it now. It has been some three or four years since they were last painted.

ERNEST R. ROOT.

PREPARING FOR WINTER.

FRIEND DOOLITTLE TELLS US EXACTLY HOW HE DOES IT.

AS I am now busy, and have been for the past month or more, preparing my bees for winter, I thought perhaps some of the readers of GLEANINGS might like to know how I fixed them. The first thing I did was to see that all had honey enough, which should be at least 25 lbs., to last from the first of October till the flowers secrete honey next year; but as I found that I did not have enough to give all quite that amount, I have allowed only 20 lbs. to those which are to be wintered in the cellar, expecting to feed, if necessary, in the spring. To ascertain the amount in each hive I first took some average empty combs the same age as were in the hives, containing about the same amount of bee-bread, and weighed them, by which I found that the average weight of a comb was three-fourths of a pound. I then took a spring balance and went to a hive, opened it, and hooked each comb of honey on the spring scale, setting down the weight thereof. The whole was then added up, and the weight of the comb subtracted, which gave me the amount of honey in the hive. If there was not 25 lbs., I took out the combs having the least honey in them, and put in full combs of honey, which I had reserved for feeding purposes, until the proper amount was obtained. If they had

too much, some full combs were taken away from them, to be used in feeding others; and in this way all were made to weigh 20 or 25 lbs. of honey. After thus weighing the combs in a few hives, I got so I could dispense with the scales, and just count the number of pounds of honey right off by simply lifting the combs. Weighing them afterward showed that I was not one-half pound out of the way. After one gets used to this plan I consider it much better than the weighing of hives, for there is a certainty about it, secured in no other way.

After all had sufficient honey, those which are to be left on the summer stand during winter were carefully packed with chaff at the sides, in place of the side boxes which were used during the summer. As the chaff packing in the front and rear remains undisturbed year after year, this gives packing all around, except on top. For the top, I prefer (after having used all kinds of material for packing), fine basswood sawdust, such as comes from the saws in sawing sections. This is filled into common cotton cloth, so shaped as to form a cushion four inches thick, or deep, and large enough to come over the top of the brood-chamber, and half way over the chaff packing on all the sides. The reason for preferring this fine basswood sawdust is, that it seems to pass off moisture, and retain the heat of the bees during all times that any packing will pass off moisture; and at times when this moisture does not so pass off it will absorb it, even to almost the bulk of the cushion, thus keeping the bees always dry, bright, and warm. Those colonies which are to be wintered in the cellar are all in single-walled hives, having an eight-inch-high cap. This cap is turned bottom side up, and filled with fine straw, when a follower is placed on the straw, upon which I stand a moment or two, thus pressing the straw into the cap. As I am a "do-little fellow," weighing only 250 lbs., this process fixes the straw so you can handle the cap as you please, and the straw will not fall out afterward. The cap is now placed on the hive, which has, over the frames, a quilt of two thicknesses of cotton cloth, which allows the moisture to pass up through the straw and out at the cracks at the top of the cap during the fall months, before setting in the cellar. When set in the cellar, the cap is raised one-half inch above the top of the hive, resting on little blocks at each corner. As the straw always settles a little below the bottom of the cap in the middle, when thus raised it strikes the top of the hive except all around the outer edge, thus keeping the cluster of bees warm, dry, and nice, while the moisture escapes all around the outside of the hive.

The first hive is set eight inches above the cellar bottom, and the next set on top of the cap to the first one, and so on until the top of the cellar is reached. Don't understand that I have set the bees in the cellar yet; for from the 15th to the 25th of Nov. is the time I usually do this; but I have them all fixed but setting in.

G. M. DOOLITTLE.
Borodino, N. Y., Oct. 16, 1885.

Friend D., I agree with you exactly in all you say in the above; but with our chaff hives we prefer about a peck of loose chaff spread directly over the sheet of burlap, before putting down the chaff cushions. This peck of loose chaff is spread all around so as to fill all the corners, and absolutely prevent any bee from getting into the upper story or around the ventilators.

SHIPPING BEES FROM FLORIDA TO THE NORTH.

CAN IT BE MANAGED SO AS TO PROFIT ALL PARTIES, INCLUDING THE EXPRESS COMPANIES?

I WISH to continue the subject-matter of Mr. J. H. Martin's letter, and your remarks, on p. 661, GLEANINGS for Oct. 1. I am glad you feel you ought to help the Florida bee-keepers, and I am sure we are willing to help the Northern bee-men. But, can we help each other in a business way? Can shipping bees by the pound from Florida to the North be carried on so as to leave a profit at both ends of the line? If we could only get in our crop of honey, and then send you our bees in time to gather yours, how nice it would be! but I fear we can not do this completely. How late in the season could the Northern bee-keepers receive bees in order to gather both basswood and white-clover honey? In sections of Florida where the cabbage-palmetto and mangrove grow, the bee-keeper would not want to dispose of his bees in May, because these plants bloom in midsummer; but in all sections like this where I am, there is only the orange and saw-palmetto. The former, last spring, was unusually late, I was told, and I presume the saw-palmetto is generally in bloom the latter part of April. Now, it seems the Northern bee-men could afford to pay a good price for bees, if they could get them in time for white clover and basswood; and it seems the Southern man would profit by disposing of his surplus bees at a moderate price, after the saw-palmetto bloom fades away; so the difference between a "good price" and a "moderate price" would go to help the express companies, that you, Mr. Editor, seem to have so much sympathy for. How many bee-keepers in the North are anxious to undertake Mr. Martin's plan next year? I am anxious to study into the matter, and talk it over with some of the Florida brethren, and we can let you know what we are ready to do. Of course, to make a success of it we must profit by Mr. M.'s experience. I presume transportation facilities were incomplete in his case. This place, Orlando, is connected with the North by an all rail route, and trains leaving it arrive in New York in 50 hours, and in Cincinnati in about the same time.

Now in conclusion, Mr. Editor, let me ask you to make some remarks on the subject—show us your "German thought and Yankee ingenuity" by placing before us some of the things which lie behind the scenes.

My bees have been working nicely for a week or so on goldenrod and other fall flowers. The weather is delightful. Oranges are not ripe yet; but lemons are picked before they are yellow, and were being shipped all last month and this.

Orlando, Fla., Oct. 15, 1885.

L. W. GRAY.

Friend Gray, it does not seem to me as though there is very much left for me to do in regard to the matter. You in Florida will have to decide how low you can furnish bees by the pound, and get your express agent to have his company decide how low they can afford to carry packages of bees by the hundred pounds—say to New York and Cincinnati, as you have it; then we in the North will have to decide what we can afford to pay; and if we get up a trade, all that remains is to work out some plan that will enable the bees to stand a fifty-hour trip safely. It just now strikes me that it

would be much more agreeable to the bees, and better for all parties, if they could be sent to some Northern point by water instead of rail. I think they would stand 100 hours by water better than 50 hours by rail; and very likely they would be worth more when they got to their destination. Can you or somebody else tell us how many hours it takes a steamboat to make the trip, and could it not be managed so that the expense of shipment would be less? We could not afford to pay a good price for bees unless they could get here before the white-clover bloom, although a little further north they might gather quite a crop of honey, even if they did not arrive until the first of July. I am inclined to think that nuclei might be better than packages of bees by the pound, because you could then put in good full combs of brood; and shipping bees in the shape of brood is a very compact and safe way, where you can manage to avoid having the combs broken down. With wired combs, and transit by steamship, there ought not to be a bit of trouble; and to make the thing work nicely, some man located at a point where the steamships stop should buy the bees in large quantities, keeping, say, 1000 colonies to fill orders. He could then purchase large consignments, and he could ship by express to the interior of the States, and sell at a moderate figure. The same thing could be done along the line of our large rivers. We are doing considerable in this line, but we purchase our bees from parties who raise them within five or ten miles of us; for we are not located so that we could afford to purchase profitably from the South.

A NEW NAME FOR HONEY-DEW.

A NAME THAT IS TRUTHFUL, AND AT THE SAME TIME NOT UNPLEASANTLY SUGGESTIVE.

FRIEND ROOT:—I have just read the interesting article by Prof. Cook, on "Plant-louse Nectar," on page 703, GLEANINGS for Oct. 15. I see a distinctive appellation is wanted that will characterize this product, without conveying any unpleasant or unfavorable impression, and yet be literally true. I would suggest that we call it

PLANT-NECTARINE.*

for the following reasons: Because it is descriptive; it implies the origin and the quality of this curious product.

Strictly speaking, its origin is in the plant, although it undergoes its transformation in the body of the plant-louse; therefore it may be truly described as plant-nectarine. The word "louse" is useless.

The origin of honey is in the flower; but it undergoes its transformation in the body of the bee. But we do not use the word "bee" in connection with honey, and therefore we may dispense with the word "louse" in this case also; and in getting rid of it we lose all the unpleasantness that it suggests, and of which you complain. The same may be said of the Latin word *apis*, though it is, perhaps, less objectionable.

We will not speak of "bug-juice." You rightly say that both "honey" and "nectar" are misnomers, when used to describe this secretion; neither is

* Pronounced Nek-ta-rin, not rine.

"honey-dew" correct. "Plant-nectarine" is both accurate and descriptive, the real meaning of the word *nectarine* being "sweet as nectar." Here is a name that commends itself as being accurate, euphonious, and descriptive; and it is not Latin, but musically pure English. FREDERICK D. WEBLEY.

Lane Park, Florida.

So far as I am concerned, friend W., I should like the word "plant nectarine" well enough; but I should be very glad to have Prof. Cook's opinion in regard to the matter. We have had so much trouble and confusion with names picked up at random in times past, that I should greatly prefer that we consider well before deciding upon any name.

ANOTHER PLAN FOR MAKING A QUEEN-CAGE.

SOMETHING EASILY MADE, AND THAT OFFERS QUITE A GOOD MANY DECIDED ADVANTAGES.

IT causes so much trouble and expense to make changes in regard to any implement so generally used as a queen-cage. I have more than once decided that I would advise no more changes, unless the new article possessed very great merit. Another thing, although the cage figured and described below has never before been presented exactly as the inventor shows it here, yet quite a number of the brethren have been figuring on different devices quite similar. It is probable that this invention, like so many others, belongs to so many that it is a hard matter to say just whose property it is, if, in fact, it can belong to any one individual.

COSTELLO'S QUEEN-CAGE.

The only woodwork in this cage is the irregular-shaped block shown at the right. This block is made of 1½-inch plank, bass-wood preferable. Strips are sawed off from the plank, 2½ inches long; then with a buzz-saw with a suitably beveled platform, a three-cornered piece is taken from the whole length, from two corners, in such a way that when you slice off the pieces, they will be like the block above. The dimensions are—thickness, ½ inch. The length of the longest side, as before mentioned, is 2½ inches; length of the longest sloping side, 1½ inches; length of the short sloping side, ¾ inch; length of the remaining side, 1½ inches. This last-mentioned side is at exactly right angles to the longest side first mentioned.

Two blocks, like the one described above, and a piece of common wire cloth, 3 x 4½ inches, make the cage. The wire cloth is folded in the middle, and fastened to the blocks by tinned tacks, as shown in the cut. This leaves a space between the two blocks, to hold the candy, ½ inch wide at the narrowest end, and nearly ¾ at the widest end. A piece of stout manilla paper is placed under the wire cloth, on each side, where the candy comes. The tacks that hold all together hold this paper in place.

When the cage is finished, the bees and queen are put in at the opening where the candy is to be put. After the bees and queen are in, soft candy is pushed into this conical opening until it is filled. For a cover to the candy, get out a piece of tin, 1½ x ½ inch. Prick a hole exactly in the center. Put a single wire nail through this hole; drive it into the wood at one side of the opening. When the tin is turned over the candy, the opening is closed. When the cage is to be put into the hive, swing the tin until it stands at right angles to the cage, and it will keep the cage from dropping between two combs, at the same time leaving the candy orifice open. The bees liberate the queen by digging through the candy. If they should not get through in 48 hours, cut out the candy with a penknife.

When the cage is to be sent by mail it is slipped into the wooden case shown at the left of the picture. Two wire nails driven in the proper place make the package so secure that there is no need of tying it up with paper unless you choose. Printed directions for introducing can be put on one side of this wooden case, and the address and postage-stamp on the other side.

When two cages are to be sent to the same address, the wooden case is to be made double length; for three, triple length, and so on. Where queens are shipped almost daily, these different-length cases can be kept in stock. This makes a much stronger package than tying them together with strings, or tacking them together with tacks, as we have had ample experience; and it is also a good deal quicker done when you are in a hurry to catch the mails.

I see only one drawback to this cage, and that is, that we can not cage a feeble queen directly over a piece of comb containing brood and unsealed honey, as you do the Peet cage. I have not decided whether we shall use it or not; but I give it to you to think about and experiment with, if you wish. Here is what friend Costello says about it:

I send you to day a shipping and introducing cage. If there is any thing novel about it, I should like to have your comments. I do not claim this cage to be wholly original. Put the queen and bees into the cage through the candy hole; fill with candy after the bees are all in.

C. W. COSTELLO.

Waterboro, Me., Sept. 7, 1885.

NOTES ON GLEANINGS FOR OCT. 15.

AND SOME KIND WORDS AS WELL.

GLEANINGS for Oct. 15th is at hand, and is worth to me more than the price of the entire year's subscription. Your articles are generally read by me to the whole family (there's a lot of us too), and excite much favorable comment and discussion. Says one, "That article (Our Homes) is worth five such sermons as we heard from the pulpit to-day," and I heartily agreed with the speaker. Continue to give us just such plain, rambling, practical talks, and you will never lack for readers. GLEANINGS can not be injured by inserting articles from such a live man as T. B. Ferry, either, even if he is not a bee-keeper.

A DISEASE OF THE BROOD THAT IS NOT FOUL BROOD.

I have had two cases of diseased brood, as described by Milton Hewitt, on page 609. One colony died last winter, and the other seems to have been cured by a change of queen. There was no smell whatever. The brood seemed to shrivel up, dry, and be removed by the bees. A frame of brood, with sealed queen-cell, and adhering bees, taken from the diseased colony, and given to a queenless colony, did not carry the disease with it. Both colonies were blacks. On page 504 of *A. B. J.* for 1883, Mr. H. L. Jeffrey describes a very similar disease, under the name of "Desiccated Foul Brood." He states the disease to be contagious, and much to be dreaded. Perhaps he can give us further light on this question.

The editorial in regard to deep and heavy foundation, vs. shallow and light, leads in the right direction. Hereafter I shall use no foundation in the brood-chamber heavier than eight square feet to the pound. My experiments with foundation during the past two seasons lead me to agree with Messrs. Doolittle and Hutchinson, that "it doesn't always pay," when producing comb honey. Still, I am loth to accept any less perfect work than we get by using the full wired sheets of foundation.

Mr. Doolittle, I see, has "looked horns" with Mr. Heddon on the question of preventing after-swarms. I must have gotten the "hang" of the Heddon method, for it works successfully with me, and I can certainly no more tolerate the improvements (?) suggested by Mr. Doolittle than I can the use of the cumbersome chaff hives. Is not Mr. Doolittle's cause of failure given in his last paragraph on page 706, where he says, "When I could be on hand, etc.?"

It is indeed true, that Mr. Heddon has a system "all his own," and withal so perfect a one that no progressive bee-keeper who becomes familiar with its details will practice any other.

How to secure the nectar secreted within reach of his apiary with the least possible expenditure of labor and capital, is the problem that Mr. H. is trying to solve; and all his fixtures, methods, and writings tend to its solution. They should be criticised from the standpoint of the specialist only.

The veteran bee-keeper of 15 or 20 years' experience is very apt to become prejudiced and wedded to his own peculiar fixtures and management, and so often views with disfavor the innovations and improvements of this progressive age that we often prefer the judgment of the enterprising apiarist of four or five years' standing to that of the life-time bee-keeper.

DWIGHT FURNESS.

Furnessville, Ind., Oct. 18, 1885.

SOMETHING FOR THE JUVENILE BEE-KEEPERS.

A SLEIGH AND WHEELBARROW ALL IN ONE.

OUR enterprising friends who manufacture the "Bee-keeper's wheelbarrow," of which we have sold so many, have finally remembered the small people usually found around bee-keepers' homes, and they make us a gas-pipe wheelbarrow, all iron except the box, on the same plan of their large wheelbarrows. Not only

is it a first-class good stout wheelbarrow, but when the snow comes (and you know it is coming soon) the handles can be unscrewed, the wheel taken off, a pair of runners put on, and—hurrah boys! *ain't* that a daisy sleigh? You will see how it is by the pictures below.

WHEELBARROW FOR THE JUVENILE BEE-MEN.

THE SAME, CONVERTED INTO A SLEIGH.

You will notice that the runners are all of iron, and the sleigh stands up so high that it will go through deep snow, if need be; and when you are riding down hill you sit up like a man, instead of being down nearly level with the ground. We use a wheelbarrow here at home a good deal to go to the postoffice; and when there comes a big snow the wheelbarrow has to be stowed away somewhere, and the sleigh be got down. Now, with this arrangement we can have them all in one. If there is sleighing, you are all right; and if there comes a muddy time in winter, you are all right. I don't know how long it takes to make the change, but I presume not very long.

May be you would like to know what this nice little implement costs. Well, the price for the wheelbarrow alone, without any sleigh attachment, will be \$1.50; with runners added, 25 cts. more. For an order of 2 at once, 10 per cent off; 3 or more at one time, 15 per cent off. Tens or hundreds rates given on application. The handles are of gas-pipe, $\frac{1}{4}$ inch inside. The weight of the whole complete, is only 9 lbs.

In regard to the use of such a tool, it seems to me that it ought to be a paying investment in any family where there are small boys; for a boy only 2½ years old can do considerable marketing, and carry a pretty fair load with a little cart or wheelbarrow. You see, we know about this at our house, for Huber does quite a good many errands with his cart and wheelbarrow. Only day before yesterday he was sent for coal oil, and brought it back all right, and probably did it just as well as a man or woman could have done it. He will carry quite a load of apples, turnips, sugar, or whatever else may be wanted; and while it is the tallest kind of fun for him, it saves his mamma a good many weary steps,

SHIRKING RESPONSIBILITIES.

WHY FRIEND DANIELS DOESN'T LEND HIS HARROW ANY MORE.

FRIEND ROOT:—You have told so good a harrow story that comes so near my own experience in that line, I am tempted to relate it, as it will give you one more glimpse of certain phases of human nature that you rather seem to think indicate "whole-souled fellows." Well, here it is:

One morning I was accosted thus by Mr. S., a renter: "Mr. Daniels, Mr. R. sent me down to see if you could lend me your harrow to put some wheat in that I am sowing on his place."

"Yes, Mr. S., you can have it. But I shall want it in a few days to put mine in."

"All right; we shall not be using it long."

I waited two weeks before I really had to have it, and it had not been sent home. Then I was in a hurry, and started to hunt it up. I saw it over in the middle of the field, where they had finished and left it. I went to see Mr. S., to have him bring it home. He said Mr. R. was to furnish him tools; and if Mr. R. had not taken it home yet it might stay there. I went to see Mr. R., and told him what Mr. S. said. Mr. R. remarked that he didn't borrow the harrow; and if Mr. S. did not take it home, he wouldn't.

I said, "Mr. S. was your tenant, and got the harrow through your influence, and you ought, as a gentleman, to bring it home."

He said he told Mr. S. that he could get a harrow of me, but that was all. I told Mr. R. that if a tenant of mine should use my word, and get a tool of him, I would take it home. He said he was not that kind. So I took a sled and went after my harrow.

Such, Mr. Root, is one of my experiences in lending harrows, and it has done me worlds of good, for I then and there swore off from lending a harrow (that much-abused tool), and I think I have ample excuse, and have been amply paid for my trouble in going after my harrow, and all my neighbors understand it. This is not written for publication. It is written to you, Mr. Root, and I have given vent to my feelings to at least one man. But I believe that such examples should be held up to the scorn of the world, and not be considered "whole-souled fellows." If they should happen to have a handle to their name, as "Dr.," or "M. D.," it is no better. I want men who have a sense of justice established in their hearts.

S. DANIELS.

Pine Grove, O.

I have given place to the above, because it illustrates so well the point I wish to bring out. There are many quite good people in this world who are in the habit of doing something quite like the neighbors mentioned above, in claiming that they have wronged no one. Now, the truth is, that responsibilities rest on us a great many times when we have individually been in no way at fault. A few days ago a paragraph in the newspapers mentioned the case of a young woman who jumped into a canal to rescue a drowning boy. Some men stood around, but made no attempt to do anything to save him. They might have said, "The boy got into the canal himself; we had nothing to do with it whatever." They might have gone further, and claimed it was none of their business. But it is our business—every one

of us, to help anybody who is suffering, and it seems awful to think there are people who will borrow tools, and refuse to bring them home, under just such circumstances as the one mentioned above. One claims that the responsibility rests upon "t'other man," and "t'other man" claims just the reverse. Friend Daniels, suppose you put the matter this way: "Suppose, neighbor, I had refused to lend my harrow, who would have been the sufferer?" The moral seems to be, that it is a very bad practice indeed to get in a way of borrowing, or lending either.

Not an hour ago I sent for a mortar-box which has been lent for several months. I wanted a mason to go to work at the walls of a greenhouse, before our pleasant fall weather was ended. In fact, a storm is pending just now. When one of my men got there with my horse and wagon the box was in use, and they could not spare it without very great trouble and expense, so he came back without it. If I should stop right here you might reasonably accuse me of the same uncharitableness I have been talking about so much lately; but I am very glad to be able to add, that the neighbor who was using it sent word to me that I should go to work and make a new one at *his expense*. Now, that is what I call Christianlike. I felt happy about it as soon as the message was delivered; but instead of putting our neighbor to this expense I concluded to take the risk of putting my work off one day more; and even if it does rain, I am not going to feel cross about it.

HOW TO SELL COMB HONEY AT FAIRS.

ALSO SOMETHING ABOUT THE WIDTH OF SECTIONS THAT WILL BE WANTED FOR NEXT SEASON.

WE take the following from the *Canadian Bee-Journal* of Sept. 30:

At the Toronto Exposition it was very easy for a person passing through the honey-house to perceive the simple and easy method of disposing of sections which had been but partially filled out. Thousands of sections may be sold at every fair by the method there adopted. We think the credit is due Mr. J. R. Hall, of Woodstock, as the first who commenced selling in this way. It is done by cutting the sections from corner to corner, making four triangular pieces, laying them down on the wood, showing off the honey to the best possible advantage. The pieces sell very rapidly at five cents each, giving you twenty cents for each section. It would not pay to take sections that contained a full pound or more of honey, and cut them in this way. Every year bee-keepers are getting more and more into the habit of using thinner sections; and we are becoming convinced that sections more than $1\frac{1}{2}$ or $1\frac{3}{4}$ inches are too thick to be profitable. We do not think many of our customers will use sections thicker than $1\frac{1}{2}$ inches, perhaps not that thick. Cutting up the sections, and selling the pieces at five cents each at the exhibition, has become so popular that there must have been twenty-five or fifty thousand people fed with honey during the two weeks' fair.

We intended to try the above at our own county fair; but unfortunately our apiary of about 400 hives is less than a fourth of a mile from the fair-ground, and there were so many bees around our honey-stand during the whole three days of the fair that we dared not undertake to cut up comb honey. —I agree with friend Jones exactly in regard

to the width of our section boxes; and my opinion is, that very few will be called for wider than $1\frac{1}{2}$ inches, after bee-keepers get used to this thickness. Of course, they do not hold a pound; but as comb honey is always sold by the weight with us, I do not think it will be an objection. On the contrary, I think more honey can be sold in a package costing at retail from 15 to 18 cents, than by using a section that holds more. At least, that is the case in our vicinity.

REPORT OF THE CONVENTION IN THE CANADIAN NORTHWEST.

A REPORT FROM MANITOBA.

THINKING perchance it might be of some interest to you to hear what is being done in apiculture in this far-off Canadian Northwest, I beg to report that, during the time of the Manitoba Provincial Exhibition last week, a convention of bee-men took place, and an organization under the title of the "Manitoba Bee-keepers' Association" was formed, with Chief-Justice Wallbridge, President; Thos. Collins, Vice-President, and J. Hammond, Hon. Sec. An exchange of experiences among the brethren elicited the following facts:

1. That cellar wintering with chaff packing had resulted most successfully in this part of the world during the past exceptionally severe winter.

2. That there is with us, owing to the numerous and varied sources of supply, an uninterrupted flow of honey and pollen from the very first opening of spring bloom till the occurrence of frost; and that, except when hindered from working by bad weather or high winds, which are very prevalent here, or from defective management, the bees continue brood-rearing without a break throughout the entire season.

My queens are still laying at date of writing, without the stimulus of feed. In this connection, Mr. Vaughan, of Selkirk, Manitoba, stated he had started in the spring with one nucleus, and from this had resulted no less than seven swarms, five of them in strong condition. Our brother being anxious to secure at least some surplus honey, was not quite satisfied with this state of things; but, by the way, friend Root, what a glorious time he might have had if he were only running a "bees by the pound" business!

3. That our work this year would furnish but a very imperfect clew as to the favorableness or otherwise of the past season for honey, as all the brethren had been running mainly for increase of colonies with surplus honey put down as a secondary consideration. It is my opinion, however, that the frequent recurrence of high winds and wet and cloudy weather that characterized the greater part of the summer, warrants me in placing the honey harvest at away below the average.

At our exhibition the entries in the bee-line were as follows: Three of Italian bees, two of comb honey, one of strained, and one of implements—not a large exhibit, you may say; but recollect, it is only a beginning, and, judging from the zeal and enthusiasm evinced by the brethren at the convention, there will be a very different turnout next year.

Friend Root, to appreciate our work it must be borne in mind that we are all novices, struggling

against severe and untried climatic conditions, so that our efforts in a measure must necessarily partake of the nature of experiments. We have much to learn, and perhaps quite a little to unlearn, in order to adapt our methods to the requirements of the country. Nevertheless I am convinced we have good material in our new bee-keepers' association, such as will by no means be content to accept whatever difficulties there may be in the way as impediments to successful bee-keeping in Manitoba.

J. HAMMOND.

Winnipeg, Can.

Friend H., wherever it will pay to raise bees by the pound, it will certainly pay to raise honey; for bees never breed in the way you mention, unless there is honey to be obtained; and when you build up to strong colonies, instead of encouraging increase so much, you will find that you will have good crops of honey.

DO BEES STEAL EGGS?

AN ITALIAN THIEF STEALS AN EGG OF A BLACK QUEEN.

SEEING friend Knox's article, headed "Where did the egg come from?" has induced me to give my experience with a nucleus colony of Italians. I made the nucleus the 1st of May, composed of four frames. They raised me a fine queen from an egg. I introduced this queen to a colony of blacks when one day old. I gave the nucleus a cell just sealed. This one hatched in due time. I took this queen away and gave them the second cell. They hatched this cell in five or six days, and killed the young queen next day after hatching. I let them go five days—no young brood, no eggs, no cells started, so I gave them the third cell. They killed this queen after hatching. I then thought I would let them have their own way, and go without a queen, which they did for three weeks. Then I thought I would give them some eggs from a choice queen from Dr. J. P. H. Brown. On opening the hive to give the eggs, behold my surprise to find a queen-cell about half built, with a very young larva in it, two or three days old. I knew at once they had gotten it somewhere else, so I did not give the eggs, and in 13 days they hatched this queen, and I tell you she was as black as a crow. This is a case beyond a doubt, where an Italian thief stole a black egg.

This queen I kept until her brood was hatched, and they were common blacks.

HOW A YOUNG QUEEN KILLED HER WOULD-BE RIVAL IN THE CELL.

I also held a frame containing a queen-cell about ready to hatch, and saw a young queen just five hours old cut a hole in the side of it, and deliberately sting the young queen within the cell. She repeated the sting three times, and then went on, I suppose looking for another. The bees went to work at once to tear down and drag out the dead queen, and in about half an hour they had the job completed. Now, friend Root, if these facts are worth publishing, you are welcome to them.

R. B. WILLIAMS.

Winchester, Tenn., Sept. 26, 1885.

Friend W., you have given us something very important indeed. We had long ago surmised that bees do, under certain circum-

stances, steal eggs; and your singular experiment seems, so far as I can see, to be evidence almost positive. The next question is, How did that Italian bee succeed in getting access to a brood-comb? If the bee slipped into a black colony in the way that robbers do, and obtained an egg, and got out again, it is one of the most wonderful promptings of instinct that have ever been recorded. This worker-bee was a hero. The safety of the whole colony depended upon him, and he, like a brave patriot, risked his life for the possible chance of obtaining relief for the rest of his fellows, and succeeded. We have had record before, of the way in which a young queen cuts open the queen-cells and stings the occupant, but your account of it is very plain and clear evidence. Many thanks for your communication.

FALSE STATEMENTS IN REGARD TO THE HONEY BUSINESS OF OUR COUNTRY.

As a protection to our bee-keeping population, we propose in this department to publish the names of newspapers that persist in publishing false statements in regard to the purity of honey which we as bee-keepers put on the market.

THE following is sent us, clipped from the N. Y. Weekly Tribune of Oct. 7:

COUNTERFEIT "COMB HONEY."

Mr. George A. Stockwell draws attention to what we have reason to believe is a widely prevalent and growing evil—the adulteration of honey, not only by mixing a large percentage of glucose with the extracted product, but by means of "fed apiaries," where sugar and water is supplied to the bees, which deposit it in the comb. He tells *The N. E. Farmer* that "the market is galled" with this counterfeit, and gives the following items of observation and experience:

"The bee-keeper delights to watch the bees as they come and go. In the busy season they drop upon the alighting-board as fast as drops of rain, and faster than man can count they are leaving the entrance for the fields. The ceaseless activity is inspiring as well as interesting. But in a fed apiary the scenes are different. The young bees and the drones may play in the sun in front of the hive, but the hurrying workers are not seen as in other apiaries. Where are they? They are within the hive carrying syrup from the feeder to the combs. They are active, but active in what? In counterfeiting! The blame lies with the bee-master, who employs bees to build comb around sugar syrup that he may sell for honey. There is profit in selling for twenty-five cents what cost five cents or less, but, in the long run, there is no profit in dishonesty.

The honey obtained by feeding granulated-sugar syrup has an attractive appearance in the comb. It is white, so called, but there is also a dull, bluish tinge that tells its history at once to the practiced eye. If this counterfeit were sold on its merits, no one would complain; but it is sold for honey. A bee-keeper carried to market pure comb honey. Some of it was white, not the bluish white, some was dark, and some yellow. The dealer would not buy. "I could never sell it," he said; "but if you can produce honey like this" (pointing to a can of sugar honey), "I can dispose of it." The bee-keeper was disgusted. His pure honey could not compete and win with sugar and water. Let buyers demand honey, and not accept at any price what is not honey. That will give sugar and water a cold shoulder, and drive it out of the market.

Now, if we knew where Mr. George A. Stockwell lives we might have some chance of refuting this slander on our industry. If there is an apiary in our land where comb honey is produced by feeding bees sugar syrup, let us hold the man up until he quits the business. I do not believe there is a word of truth in the statement, that adul-

terated honey ever brought a better price than a good quality of the genuine article. Will the *Tribune* please take notice, that they are greatly wronging an honest and hard-working class of people by giving place to statements like the above, which are entirely untruthful?

ANOTHER.

I mail you a copy of the *Lafayette Daily Journal*, which has an article on first page, headed "The Busy Bees' Occupation Gone." Please read it. Oxford, Ind. JAS. CAMPBELL.

Below is the extract from the *Daily Journal*, of Oct. 16:

THE BUSY BEES' OCCUPATION GONE.

The spurious honey is now put up in little square boxes, which sell for from twenty to thirty cents a pound! It looks like honey, and it is said that it takes an excellent judge to tell that it is a fraud on the bee.

The comb is manufactured with such skill that but few can tell it from the genuine article. It is made from paraffine or beeswax, and the honey is blown into it by machinery.

Another kind is put up in glass vessels like ordinary jelly-packages, the center of which contains a piece of honey-comb, and the honey is made by pouring about six parts of glucose around one part of honey in the comb. Some of it is adulterated with glucose, some with cane sugar, with the syrup of inverted cane sugar and others by heating ordinary sugar with an acid; but it all resembles honey, and to a certain extent has its flavor and odor.

As there is no name or signature to the above item, we are forced to believe that it is an editorial, or written by one of the reporters. Will our friends of the *Journal* take notice, that the above is absolutely false, and that we have for more than a year been trying to find out a single case of the kind mentioned. The comb honey in little square boxes is genuine bees' honey; and not even an attempt has ever been made to imitate it. We stand ready to go to any needful expense to ferret out this whole matter, and prove what we say. There is this much truth in regard to the last part of the paragraph. There are glass vessels on the market, containing a piece of genuine comb honey; but as all honey candies as soon as the weather becomes moderately cool, the proprietors of this kind of package use what they call corn syrup to pour around the honey—or rather, perhaps, a mixture of honey and corn syrup; but every jar of this honey has the matter fully explained by a label, so that every purchaser knows exactly what he is getting. If honey can be procured that will not candy at the approach of cool weather, it would probably be used instead. So far as manufacturing comb honey is concerned, it is both untrue and impossible.

Please read this little slip of paper; and as you read, understand it was clipped from that best of all agricultural journals, the *Rural New-Yorker*. If you think best to notice it in GLEANINGS, do so.

Borodino, N. Y., Oct. 16, 1885. G. M. DOOLITTLE.

S. W. M. Griffin, Ga.—Bishop Clark, of Rhode Island, in a late New-York paper, says that men, without the aid of bees, now make and sell "comb honey," in which neither wax nor honey is used; that the comb is made of paraffine, and filled with substance resembling honey. If this is true, it is a death-blow to the honey trade; if not true, the agricultural press ought to contradict it.

ANS.—It is probably true; but the sale of such imitations must be limited to those ignorant of the properties of genuine honey. Such concoctions

will not be a death-blow to the honey trade any more than the sale of oleomargarine and similar imitations has been a death-blow to the dairy business. Of course, such frauds injure fair trade, but they can not destroy it.

Many thanks, friend D., for the clipping you send us. You are right in protesting, when things come to such a pass that men so well posted as the managers of the *Rural New-Yorker* should print such things. I refer to the single expression in their answer, "It is probably true." Now, friends of the *Rural New-Yorker*, and the rest of the agricultural press of America, if nothing else will satisfy you that you are misled and humbugged, I will pay \$1000 to any man or woman who will show me an establishment where they make and sell comb honey in which neither wax nor honey is used. Now, will our friends of the agricultural journals please be as willing to put down a damaging slander as they have been to give it publicity? They can, any of them, easily satisfy themselves as to whether I am good for the offer I have made.

To show the estimation in which fraudulent bee-keepers are held by the different bee-journals, and by apiarians as a class, we have only to clip the following item from the very next column of the *Tribune* from which the extract on preceding page was made:

Mrs. Lizzie E. Cotton, West Gorham, Maine, is referred to as a "fraud" by *The Industrial Journal*, which states that all the apicultural papers reject her advertisement, and accuses her, among other delinquencies, of having "advocated feeding bees sugar and calling it honey."

A BEGINNER'S EXPERIENCE.

SOMETHING FROM THE PLACE WHERE MR. LANGSTROTH LIVES.

I HAVE a few suggestions regarding bee-keeping, and I thought I would submit them to you for your opinion. In bee-keeping I do not claim to be any thing but an amateur. Three years ago I bought one swarm from Bro. Mc Cord, of this place. By close attention, and the assistance of the A B C, I got along finely, losing but one swarm in hiving. Last fall I closed the season with 32 swarms in good condition. I was called away from home in October for some three weeks, and business was pressing me so close I did not find time to look at bees again until January, when on opening I found two swarms starved to death, and several short of honey; but I began feeding strong, and pulled them through till April, when they began to drop off, and continued to until I had only five stands, and they in a weak condition. One of them was queenless. I succeeded in saving the five, and now have increased them to fifteen. All have laying queens, and, as father Langstroth says, my chances are good to pull them through by a little feeding.

I came near being a blind bee-man a couple of weeks ago. I found that the moths were working in some of our frames, and concluded to sulphur them on a large scale, so I gathered up seven Simplicity hives, leaving the lower two empty. I then placed a coal-oil cook-stove in the bottom of the hive, with a small iron vessel to hold the sulphur. The sulphur part was a success, of course. A col-

umn of nine Simplicity hives, one on top of the other, with a cover on the top, made a splendid smoke-house. So far, so good. I took my hives down, and found the moths all dead. I then put the frames away; but when I went to put the stove away it would not move. I think in raising the stove out of the bottom hive I threw the flame down in the stove, which caused the explosion. I was burned pretty badly on head and face, but my eyes were not injured, though my eyelashes were singed. I would advise all persons to put out the flame entirely when they attempt to move a stove. I shall the next time.

I send you a sample feeder. A bee can not drown in it. You can use it outside or inside of hives. You can regulate the flow just as you want it. You can use it to furnish water inside of hives, when you are feeding sugar; and the beauty of it is, almost every home in the land has feeders on hand. I send you a small one for sample. I have them up to a quart in size. If you wish a freer flow of honey, you have only to take the scissors and cut a few more notches, and bend those back. I send you one more miniature sample of my winter feeder, embracing the Hill device for clustering, and feed at hand in shape of candied sugar. I also claim that the candy will absorb some if not all the moisture, which is so damaging to bees, and also keep the candy in better shape for food. My object in dividing the sugar-frame is, that when one portion is taken out, by having a duplicate mold you can make another cake of candy, and insert it when needed. The first expense would be trifling; any bee-keeper could make the frame and the mold to run his candy blocks in. I think by using this, if extremely cold weather should catch a swarm in a part of the hive where honey is scarce, they would have feed at hand. If hung in the shape of the Hill device, would it not tend to cluster them more in the center of the hives? This feeder is intended to cover all the frames in the hive. I have put a portable portico to some of your chaff hives, to rest the feeder on, and to others a simple rest for feeder.

Father Langstroth was out yesterday, and says my stocks are in splendid condition, and I certainly have the bees. With a little more feeding I am safe. The season has been poor here. One of our largest bee-keepers has lost some stands from starvation this summer.

HORACE WELLS.

Oxford, Ohio, Sept. 2, 1885.

Friend W., I am inclined to think that the oil used in your coal-oil stove was of a poor quality, or such an explosion would not have resulted. I have often fumigated combs in the way you mention, only I had a box at the bottom, with a door in it, so a dish of live coals could be set in through the door, and a roll of brimstone afterward thrown on the coals.—The sample feeder you send is only a modification of the Haines feeder, shown in our price list and A B C book. A glass tumbler inverted in a saucer will answer the same purpose, only you can not snip into the edge of the tumbler with a pair of scissors, as you can a tin cup or tin can. I will explain to our readers, that the winter feeder is a little frame with partitions across, and the space between the partitions is filled with candy. This might have some advantages, but lumps of candy

laid on top of the frames answer almost as well. We are very glad indeed to get a word from our good old friend Mr. Langstroth, and rejoice that he is able to be out among the bees.

BUILDING UP NUCLEI IN FLORIDA.

IS A QUEEN'S PROLIFICNESS IMPAIRED BY KEEPING HER CONSTANTLY AT WORK FOR MANY MONTHS?

I HAVE received and read GLEANINGS for Sept. 15. I hoped to see an article in it by an experienced bee-keeper, on "Building up Nuclei;" but as I am disappointed, I shall ask you to give me foot-notes in reference to a few questions.

Suppose I want to increase my number of colonies. After building up a nucleus to a full colony, then dividing that colony and keep on feeding till it builds up again, then dividing that colony again, will the old queen continue laying as well as at first, or does she need rest? If she will not lay as well, or needs rest, how many divisions would you advise?

Beginning to feed a nucleus a small amount of sugar, and increasing the amount as it increases in bees, what amount of sugar do you think you would be apt to be feeding by the time it gets to be a full colony?

Suppose it is summer, or think of me down here in a summer land by the way, I want to name my apiary the "Summerland Apiary," if you do not know of any by this name, and you wish to stop increasing, would you stop at once, or would you diminish the feed gradually?

QUESTIONS FOR MR. DOOLITTLE.

In GLEANINGS for Aug. 15, on page 557, in the last two sentences you speak of introducing virgin queens. Now, under this same circumstance—as introducing a laying queen would certainly be of advantage—do you not introduce laying queens when you have them on hand? If not, why not? Are the bees more likely to kill a laying queen? Would you advise a bee-keeper to follow the plan of introducing laying queens when he has them under the above circumstance? I work my bees for comb honey, and like your opinion on any thing relating to the working of bees for comb honey.

L. W. GRAY.

Troy, Fla., Sept. 25, 1885.

Friend G., I have never been able to see that a queen was injured, or made any shorter-lived, by keeping her at work continually. Even the queens that I kept laying through the winter, in my greenhouse experiments, seemed to lay just as well when spring came as those that had had a rest.—In regard to the amount of sugar required, it is almost impossible to give any answer, so much depends upon the number of bees you feed, and that depends upon the prolificness of the queen; also as to whether they get any assistance by way of stores in the fields. You can stop increasing at once or not, just as you choose. Cutting off the rations suddenly may make the bees cross for a day or two, but I can not see that it does any harm otherwise.—If you will excuse me for partially answering the question you addressed to friend D., I would suggest that you have not read your A B C

book fully, friend G. Laying queens are always much easier to introduce than virgin queens: and the only reason why we go to this extra trouble to introduce virgin queens is because of the fact that they are always recognized as being difficult to introduce under almost any circumstances. Of course, the same plan would answer for introducing laying queens, but no one would think of going to all this pains when we have established plans so much simpler.

PREVENTING AFTER-SWARMS.

SOMETHING FURTHER FROM FRIEND HEDDON.

ON page 705, Bro. Doolittle rather chides me, and insinuates that I am prone to blind adherence to certain petted plans. I hope and trust I am not guilty of any such non-progressive tendencies. I mean that my future works shall prove that I am not. Bro. D. thinks I am too conservative, because I do not at least try his additions to my plan of preventing after-swarms. I can not agree with him regarding the cause of my refusal to test the said additions. The real reasons are these:

1. As Dr. Miller recently stated, there are certain matters and principles, connected with our pursuit, that a bee-keeper of average intelligence and considerable experience can correctly decide upon, without troubling himself to put to practical test.

2. I do not need to test the speed and efficiency of additions and complications that are in no way needed.

The plan, as I have heretofore given it to your readers, being speedy and simple, worked perfectly with me, with many colonies, and in different seasons; and had it not, you may be sure I would not have presented it to the public. Many have been the private reports regarding the success with it; and I am of the opinion, that, while it may be true that it is one of the methods that will vary in varying localities, still the usual cause of failure is due to imperfections in the detail manipulation.

Perhaps in Bro. Doolittle's locality his bees are not working lively in the fields from hives that have cast prime swarms seven days previously, and he, having absorbed the *spirit* of the plan, wittingly added the precautionary measure of making the removal of the old colony, only when the young bees were out for their exercising and localizing flights. Thus by the use of his native tact and clear understanding of the principles of this method, he can now say, with the rest of us, "Success is mine," incurring no added manipulation, only the extra care of watching for the exercising flights above referred to.

Bro. D.'s "explanation" of where my old colony gets bees with which to form these second swarms is not at all satisfactory to me. My bees never act as he describes, in this locality.

My experience in manipulating bees, and the implements connected with them, tells me, without any practical tests, that my plan, when hampered with his additions, as given on page 556, is no improvement over allowing the old colonies to cast their after-swarms, and our hiving them, as of old. This is true of any apiary as well equipped for natural increase as are my own.

Regarding the "chaff hives" and "Simplicity

frames," as mentioned by Bro. D. on page 705, he does me injustice. Three times I have tested tenement hives—twice on an extensive scale. I have never opposed the Simplicity frame. Who would be so weak as to imagine a practical choice, in point of principle, between frames $9\frac{1}{2} \times 17\frac{1}{2}$ and $9\frac{1}{2} \times 17\frac{1}{2}$? Certainly, no one. I once opposed calling the latter size the *standard* Langstroth frame. My grounds were well taken, and conceded; and to-day said frame is known by its own true name, the "Simplicity frame."

You may rest assured that the readily movable shade-board and weight (stone), "readily movable," honey-board, and non-erasing crayons, will all stay by me, till some one points out something that is better, when expense, dispatch, and profit are considered.

JAMES HEDDON.

Dowagiac, Mich.

May I suggest, now, friends Heddon and Doolittle, that we let this matter drop before it gets into any thing more like a controversy, for we certainly have no space to spare? Friend Doolittle did not mean to carry the idea, I feel sure, that there would be any practical difference in the working of the Simplicity and Langstroth frame, although I must confess he left it in a way that would look somewhat so.

CLIPPING QUEENS.

HOW TO MARK THEM, ETC.

FOR three years I did not practice clipping my queens, and I hardly ever had a colony to swarm; but we had more or less trouble in hiving the swarm, in our endeavor to get them to cluster, or to get them down and in the hive. I remember on one Sabbath afternoon, while I was at a relative's near by, that a younger brother came for me, saying, "George, the bees are swarming!" On getting home I found others of the family trying to keep them from absconding, by throwing water, cloths, sticks, and whatever was most convenient, among them, all to no purpose, for they seemed bound to go away. I joined with the others, and after much hard work we finally got them settled on a fence-post at the further end of the lot, and with much difficulty we got them hived.

Now, this was not only hard work, but very annoying, as we presented a veritable show to many passers-by who had stopped to watch us, and to our neighbors, as we were where we could be plainly seen from the street in front and from the side street.

On another occasion, before our eyes, almost in our face, out came a swarm led by a queen which we considered the most valuable in our apiary, and off they went like a streak to the far-off woods.

On a third occasion, in May of the first year, I clipped my queens. I had gone on an errand down street, and on coming back I found a swarm in the air, which had just come out; my two brothers were throwing water among them; mother was beating a pan, and a next-door neighbor was ringing a dinner-bell. Well, it was laughable to me, and I did laugh. The queen was clipped, but I had forgotten to tell the folks how to hive a swarm with a clipped queen. I told them to stop; that I would soon hive them, which I did by picking up the queen, caging her, removing the old hive, placing

a new hive on old stand, and as soon as the bees began to return I let the queen run in with them, and all was done.

We now hive all of our swarms in this way, excepting that we sometimes use a swarm-catcher, and know it to be the easiest, quickest, most convenient, and handiest way; besides, we never lose any swarms as we did with the old method. We now have the other folks so instructed, that, if I am absent, any of them can hive a swarm.

We have lost but one clipped queen by swarming, and that one was stepped on by a visitor.

I don't think that the bees are any more disposed to supersede a clipped queen than any other. If they do supersede one they would do it any way, even if she had two full wings.

Laying every thing else aside, there is another very important reason why I would clip my queens, and it is this: That I so clip them as to mark them; and whenever I see one I know immediately how old she is. To mark them I clip the right wing of this year's queens obliquely off; of next year's queens, the left obliquely off; of the next year's queens, the right square off; and of the next year's queens, the left square off. Thus I have my queens marked for four years; and if I had any queen that I wished to keep five or six years, I would clip both wings; and I assure you this would do the queen no harm, as I have had queens with both wings clipped off close to the body, and they were just as good as any others. It is my opinion, that those who clip their queens, and make complaint that they are then superseded, etc., injure them while performing the operation.

REVERSIBLE FRAMES AND SECTIONS.

Although many of our best apiarians use reversible frames, I can not see that, in my method of manipulating the brood-frames, it would be of any benefit to me. I send you to-day a sample of our queen-excluding honey-board. You will notice that the slots are just $1\frac{1}{2}$ inches from center to center. I space my brood-frames just the same. I make my sections $1\frac{1}{2}$ inches wide, and my section-rack reversible, which I set directly on the queen-excluder, which lies directly on the frames; thus we have no bee-space, but get our sections as near the brood as possible. When the sections are about half full I reverse my rack, thus getting the comb built as firmly to the bottom of section as to the top. This is of much importance to the bee-keeper who sells his honey away from home, as it is not nearly so liable to break down. It also presents a much finer appearance.

I beg leave to differ with Dr. Besse and Wm. F. Clarke, although they are in the senior class, both as regards age and experience, while I am in the junior, in the matter of having our colonies go into winter quarters small instead of large and strong. My experience has taught me to have strong colonies in the fall, if I wish to make the most profit from my bees the next season; and here I would caution beginners in regard to this matter, and say, always keep your colonies strong.

I heartily indorse sister Culp's method of setting away full combs during the honey season, to replace empty ones in the fall.

GEO. F. WILLIAMS, 29-77.

New Philadelphia, Ohio, Oct. 8, 1885.

Thanks, friend W., for your sample of queen-excluding honey-board; but I can not see that your arrangement gives us

quite the facilities which are offered by a reversible frame. The board is not materially different from the Hutchinson honey-board, except that the slots run the whole length of the honey-board. Our objection to this plan was, that so long a slot, and also so long a strip of wood between each two slots, made the possibility of variations in the width of the slot much greater; that is, these narrow, slender pieces of wood are much more liable to twist or sway a little than if stayed every two or three inches.

FOOT-POWER SAWS FOR BEE-HIVE MAKING.

STILL FURTHER IMPROVEMENTS JUST BROUGHT OUT BY W. E. & J. BARNES.

ALTHOUGH foot-power is hardly sufficient for making bee-hives in any considerable number, yet such machines will always prove a boon to nearly all who are just commencing in bee culture, or who are located in places remote from power-mills. Our enterprising friends who make the machine shown below have, I believe, for years taken the lead in machines of almost all kinds to be worked by foot-power. Although we have not had the new machine yet so as to test it, we judge by the engraving and their description that it is ahead of anything heretofore in the market. We can furnish them at exactly the same prices we have been selling their old style; viz., \$35.00 for the saw as shown below, or \$40.00 with the scroll-saw attachment. The latter is needed but little if any for plain hive-making. From the above prices we can make a discount of 5 per cent where cash accompanies the order. We also include a cloth-bound A B C book with each machine, as it contains very full directions for using the foot-power buzz-saws. Below is a cut of the machine, and explanatory remarks by the manufacturers:

IMPROVEMENT IN THE BARNES FOOT-POWER SAW.

This improved combined saw will take the same attachments, in substantially the same manner of our old combined; viz., the scroll-saw-boring attachment, and the cutter-heads. The improved

machine is the result of our experience during the last ten years in foot-power machinery, and we believe it is safe to say that there is little room for further improvement. We have put out a considerable number of these machines, many with those acquainted with our old style, and in every instance we have expressions of satisfaction. The peculiar arrangement of parts avoids any strain on belts to cause friction, and yet there is no slipping of belts. The machine runs without noise, and has great power to execute the work. The gauges and adjusting parts for the various kinds of work to which it is adapted are all handy, and easily managed. For bee-keepers' use we believe it to be all that they can ask, and on our regular terms of trial. None will be returned because they fail to do the work. We still sell our machines subject to trial, asking no one to keep any machine that is not suited to his use, after he has tested it in his shop.

W. E. & JOHN BARNES CO.

Rockford, Ill., Oct. 17, 1885.

DO MARTINS EAT BEES?

DRONES, BUT NOT WORKERS, THE VICTIMS.

IHAVE been reading in the last GLEANINGS a complaint about martins eating bees, and wish to state that it is a well-authenticated fact that they do eat bees. But, what kind of bees do they eat? Has it ever been proven that they eat worker-bees? I have a nice martin-box in front of my house, and it is filled with birds every season, and my apiary is on the other side of the house. I have given much time during the past season to determine, if I could, whether they caught workers or not, and I am not able to say that they do. One thing I have demonstrated, that when drones are out during the last half of July and August, that the birds are out also, and I have seen them take drones, one after another in quick succession, but I have never seen them touch a laden worker, though they were flying right among them where there were hundreds coming in.

My bees have done better since I have had martins than ever before, and I think they are a help to the bees when they are driving out drones, if not at other times. I thought, however, that they might, through mistake, pick up a queen, and so be a damage to the bees; but I don't know it to be a fact. I think it is about the same with king-birds as with martins. I watched some during the past season. They would take their stand on a tall dead-topped tree near my apiary. I took my gun, and went out to investigate, intending to bring down the first one that took a laden worker, and so be sure in relation to the matter. But I didn't have occasion to shoot. It is singular how far they will sight a drone. I have seen them leave their perch, and, with almost lightning speed, go from 60 to 75 yards, when, snap! you would hear their bills, and another drone is not. The above is the sum and substance of my observations during the season just past.

We had a splendid yield of honey in early spring from soft maple and fruit-bloom. I took 100 lbs. in 2-lb. sections from 4 swarms before the first of June, and the brood-nest was as full as it could be packed, and I think it hindered the queen materially in brood-rearing. If I had had an extractor, I think I could have taken 500 lbs. during that early flow, and my bees would have been better off for it. Since

then the yield has been very light. They have stored a little since buckwheat and goldenrod came into bloom, but they will need it all, and many will have to be fed to carry them through the winter.

Oneco, Conn., Oct. 5, 1885.

T. B. MOWRY.

Friend M., this thing has been up before, a good many times, and I should be glad to think you are correct; but if I remember rightly, a good many reports at the time the matter was discussed showed that the crops of the birds contained *bee-stings*. The sting could be, of course, readily identified under the microscope, even if they were entirely mashed up. See "King-Birds," in the A B C book.

ARTIFICIAL QUEENS.

Are They Inferior to those Raised under the Swarming Impulse?

THOSE RAISED LATE IN THE SEASON, LONGEST LIVED.

MR. ARWINE shows by his tabulation that queens long in growing are longer lived (p. 587). So far he is without flaw, and no man can show argument against him without using smart catches that are not proof.

I can trace back, by record, every queen I have raised since 1874, their disposal, life's length in most cases, and other items of their history. I have averaged over 60 nuclei, shifting the queens as fast as laying commenced, and it is not so strange to have 5-year-old queens, because I have as many as 25 of that age already. Four and three year olds are to be found; but the singular part of all is, those queens are all out of the August and September raised queens. They are among those the least inclined to swarm, gentle to handle, and are good steady layers. The May and June queens are as bad swarmers as the swarm-cell queens, and are as short lived as the October queens. I have averaged setting up my nuclei May 12, the earliest being the 3d, the latest the 18th as a season start; usually, $\frac{1}{2}$ to $\frac{1}{2}$ the number I intended to run through the season, bringing the number up to full before the last of June. Give me, for my own use, queens from cells started in 5-frame nuclei; let them build and cap their cells promiscuously, then destroy them just at night, and give them some eggs, taking away the center comb; and though all the queen-breeders in the world speak against it, I am forced to believe what facts prove to be so under my eyes.

There is one queen coming 6 years old in Aug., 1886, that has never tried to swarm. She was clipped as soon as she began laying, and has been in the same hive she is now occupying, since Oct., 1882. She was weak in bees last spring, but otherwise good. She is the mother of well-to-do daughters to the third generation. How is that for forced, or artificial queens? Close-kept record tells me that the swarm-cell "blow" is very well, but I take my pick out of August and September nucleus cells. I don't find that so many swarm or so many fill the brood-nest with honey. Fall-raised queens get some age before being obliged to make laying a steady business. Hard steady work breaks down all young animals.

17, H. L. JEFFREY.

New Milford, Conn.

Friend J., you have suggested an idea that is at least new; viz., that a queen will live

and do service more years when hatched and fertilized late in the fall, so that she has many months of comparative rest before the great labors of swarming-time. It seems to me reasonable, and we should be very glad of reports from others when they are prepared to give us facts in this matter of much importance.

NATURAL SWARMS.

INTRODUCING A VIRGIN QUEEN, TO PREVENT AFTER-SWARMING.

IF you have no objection to the following, I should like to give to the readers of GLEANINGS, and especially those who, like myself, have had but little experience with bees, a very good way of managing bees through the swarming season—not that it is *new*, but because I find it such a simple and easy way. In the first place, I think we all want our bees to swarm as early as possible; for that reason I don't put the sections on until they really *need* them, which, of course, depends on how soon the lower part, or brood-chamber, becomes filled with brood, bees, and honey. This treatment, I think, induces them to make preparations for swarming. When a hive sends out its first swarm I let them get well clustered, and then hive them in a new hive (new to them), with two frames of comb, and the rest of the frames with foundation. As soon as they are all in, or clustered on the hive, I move them to a new stand, and gently smoke them into the hive.

This, I know, is different from the way many do; but the reason I do not move the *old* hive on a *new* stand and put the *new* hive on the *old* stand, is, it sometimes happens that the bees cluster, and go into the hive all right, but they may not have a queen with them; and if the old hive has been moved from its stand, and the new hive placed where the old hive stood, and if the queen did not swarm out with them, your new colony is queenless, and they can't go back to their old home, for they don't know where it is. If it had not been moved, however, as soon as they found they had no queen they could go back home and try it again. So much for *first* swarms; but let me add, I put all first swarms back after July 10th. Of course, I have after-swarms to deal with. I have each hive numbered, and I have a plat of the bee-yard, using a small blank card to represent each hive, and each card is numbered to correspond with hive, and is located the same as in the yard. It is about the same as going to the bookstore and selecting your reserved seats for an entertainment. When a swarm comes out, and is hived and located, I put the date and the number of the new swarm on the card on the plat, that the swarm came out of. I also put a new card on the plat-board to represent the new swarm, and put the new number, date, and number of hive it came from (double-entry book-keeping). When a *second* swarm issues, I look on the plat-board to make sure it is not a *first* swarm. I watch them until they begin to cluster, and then go to the hive and remove the tier of sections, and cut out all the queen-cells. If they have a tier of sections partly filled, and the flow of honey is good, I put a tier of empty sections (with starters) with *open tops* on the hive first and then the tier they had partly filled, on top. Then I take a well-made nail-keg, with $\frac{1}{4}$ -inch holes all around near the top

hoops, and a board about 14 inches square. Place the keg upside down on the board on the ground near the cluster. Shake the bees on the ground close to the keg, and they will almost always go in readily. When they are all clustered in and on the keg, carry it to the hive the bees came out of, and shake them out in front, and they will go in lively. It sometimes happens that I can readily find the queen in the cluster; if so, I use the Klimitz queen-cage to put her in, and hang the cage in the hive after cutting out the cells, and if they had no other queen in the cluster they will come back and save the bother with the keg. When they begin to come back I let the queen out of the cage, and let her run down the brood-comb.

When cutting out queen-cells, while the second swarm is out it is an easy matter to save some virgin queens, as they will often hatch while cutting out the cells. I keep several on hand; and after a hive has sent out a first swarm, and the excitement is over with, I run a virgin queen into the hive at the entrance. An experienced bee-man told me it would prevent after-swarming, but it has not with me. I have thought it might save a few days' waiting for a queen to hatch. What do you think about it?

I find by managing my bees this way, I get about as much surplus honey from the old colonies as from the new ones. It keeps them better equalized, in better shape for wintering, and saves lifting hives heavy with honey, from one stand to another. By letting the second swarm come out, and then cut the cells, I am not so liable to kill or injure the queen, and I think it better than cutting out all the queen-cells but one as soon as the first swarm issues; for I find it difficult to know which cell will hatch first.

My bees are doing first rate. Spring count, 56; increased to 98, and put back at least 30 swarms since July 10th. The honey-flow has been very good from all sources so far—dandelion, fruit-bloom, white clover, and now we are in the midst of bass-wood, and the goldenrod is coming on in good shape.

C. A. SAYRE, 56—98.

Sargent, *J* Iowa.

Friend S., your plan of preventing after-swarms is like many others—sometimes it answers and sometimes it does not; but I should think it would do in the majority of cases; that is, if the bees accept a newly hatched queen, they will probably permit her to tear down all queen-cells under way.

THE MECHANISM AND STRUCTURE OF THE BEE'S HIND-LEG JOINT.

HOW THE BEES LOCK THEMSELVES TOGETHER WHEN CLUSTERING.

SOME of the readers will perhaps remember, that a few years ago I made a cross-section of the bee-sting. This was the work of a whole week of hard, vexatious labor. No one but one who has handled the microscope, and made such dissections, can understand the difficulties that attend it. The sting is made of a hard horny substance—so hard, indeed, that it will break nicks in the best razor steel when cutting transverse sections. It is much finer than the finest cambric needle; and when a cross-section is obtained, an idea can be formed of the minuteness of

the work. But with the leg of a bee we do not have such difficulties to encounter; and, strange so say, as far as I can learn no one has fully investigated the structure and true relation of the different parts of the bee's legs to each other. As I have been at school for the last four years, I have not given it much study myself.

To me this is a most fascinating study; and now that a light form of the old microscopic fever has returned, I give you the results of a part of my investigation, as brought forth by a Baush & Lomb microscope.

HIND-LEG JOINT OF A BEE.

The first thing, then, that we take up is the hind-leg joint, and its purpose, a cut of which appears above. It is drawn as it appeared in my instrument, and is magnified 10 diameters; in other words, it appears 10 times as long and 10 times as wide as it really is. At X you will observe that the lower jaw, so to speak, is serrated by rows of what appear to be teeth. The opposite side of X, not shown, is serrated in the same manner. On the upper jaw is a row of sharp spurs, Z, somewhat coarser than those seen below. Just above the jaws, at the base of what is called the tibia, is something that looks somewhat like a pig's head with his mouth open; but this in reality is a series of very powerful little muscles which give motion to the joint. The question now naturally arises, What is the office of these teeth and spurs, as seen in the jaws? I confess I am not quite able to determine, without more study than I have been able to give it, so far. Possibly they may serve to masticate or pulverize the pollen so that it may be more easily patted down in the pollen-basket higher up, as at Y.

HOW THE BEES LOCK THEMSELVES TOGETHER IN CLUSTERING.

However, I feel pretty tolerably certain that I have discovered one purpose of this peculiar joint.

While looking through the microscope at the narrow neck, as it were, connecting the two parts of the leg, it occurred to me that it was around this same narrow neck that the bee, when clustering, threw his two little hooks or claws. These hooks, or claws, resemble somewhat the talons of a hawk or an eagle, and I may in a future number give you a drawing of the bee's foot. It is easy, then, to conceive that when a bee's foot has grasped hold of this neck, just as you would inclose it with your thumb and finger, his foot will be securely locked fast, if the other bee close this jaw by straightening out his foot. Feeling assured that the bees ought to link together in this fashion, I went out into the apiary to see if it were true. I was not surprised to find that such was actually the case. The apiarist and I examined a number of clusters of bees, and in almost every case we found, when linked together, the fore feet of one bee fastened firmly to the hind-leg joints of another bee. We then strung a lot of bees together in the form of a chain. The result was, that one bee, when linked in the manner described, would hold a hundred or more of his companions, seemingly, too, without any effort. To test the matter still further, I picked a bee up by the wings and allowed him to grasp hold of another bee. My object in this was to see where, if given the preference, he would catch hold. Running his fore legs down the hind legs of his companion, he grasped hold of this particular joint, and seemed to say, "Now pull me off if you can." We tried this experiment a number of times, with like results, and at times it *did* seem as if the legs of the little fellows would break, so securely were they locked. I have since been out to the apiary, this time using a magnifying-glass, and I now feel fully satisfied with the results. It is known to be a fact, that a few bees around a limb will hold as many as six or eight pounds in a swarm. Not only that, but the bees will sustain this enormous weight sometimes over night, and even much longer if necessary. Unless nature had wisely made such provision as this ingenious little vice it would be impossible for so few bees to hold such a weight.

Perhaps I should mention, in this connection, before leaving the subject, that bees do not always lock together as I have described. When the strain is not great, and the bees few, it often becomes necessary for them to grasp hold of any portion of their comrades that seems most accessible. In such cases they may be holding to each other by their claws; but if I am correct, they never use their mandibles in holding to each other.

When favorable opportunity presents you will be amply repaid in observing how ingenious this contrivance of nature is. Get the juveniles started, and possibly they may add some hints. I shall also be glad of kindly criticisms, and any suggestions that Prof. Cook may feel disposed to give. I have scanned his book quite carefully, but find no mention of this particular feature in the hind leg; though he suggests that the flute in the bees' fore leg may answer for holding on when clustering.

ERNEST R. ROOT.

P. S.—Father has suggested that the bee may put his whole foot, or, what Prof. Cook calls the *tarsi*, in the jaw, and that the claws grasp hold of the spurs or hairs. There are three little joints in the *tarsi*, forming little links, which are conical in shape. This, seemingly, would afford a good opportunity for a strong connection when the jaw closes

over it, and the bee may do so on occasion, but I feel pretty well satisfied that they prefer to grasp the little neck referred to above.

E. R. R.

HEADS OF GRAIN FROM DIFFERENT FIELDS.

FROM 15 TO 29, AND ONLY 100 LBS. OF HONEY.

I SEND in my report up to-date; viz., 15 colonies, spring count. From them I increased ten by natural swarms, three by artificial swarming, one by building up from a two-frame nucleus started in May last, making at this date 29 strong colonies, as far as bees are concerned, but not in honey, but self-sustaining. From the 29 I received only 119 one-pound sections, some not full, making 100 lbs. of honey up to date—the poorest yield I ever had, and not a very good prospect for a good fall flow of honey. But I am not out of heart, and not out of pocket, for my bees always pay for all the expense I put upon them, even if I do not get a flow of honey.

TWIN QUEENS.

Have you ever heard of twin queens, or two queens in one cell? I never have, but I saw such in one of my hives last June. I wished to raise some queens for my own use, so I removed a queen from one of my hybrid colonies; after nine days I removed all the queen-cells, and gave them a small strip of comb with eggs. They formed four queen-cells on one side of the comb, and two on the other, with one very large one which attracted my attention, so I cut into the cell and found two queens. The cell was single, except a small strip at the bottom. I wished afterward, I had put the cell in some other hive. The queens were not fast together. I suppose you will say I was mistaken; but I say I am not, for I had both queens in my hand at the same time.

JOSIAH EASTBURN.

Fallington, Bucks Co., Pa., Aug. 19, 1885.

I do not know that I ever before heard of two queens in one queen-cell, friend E.; but I can readily imagine that two larvæ might by accident grow up side by side.

HOUSE APIARY, HOW TO CONSTRUCT; FRIEND HOXIE'S PLAN.

I will give you a description of a house apiary which I have had in use about three months, and am so far well pleased with. It is 12x24 ft., 8 ft. high, boarded up and down with patent siding running up through the roof-boards, making it bee-tight. I have doors in each end alike. First a door with two large panes of glass which swing inward, then a screen-door, same size, which opens outward, with hinges that hold them shut or open. Outside of this a batten door made of patent siding, which shuts under the door cup, and wide and long enough to protect the others from rain or snow. My hives stand on the floor, and are Simplicity hives without bottom-boards. The entrance through the side of the house is the same size and shape as the hive, with the alighting-board nailed to the house outside. My hives stand four inches back from the wall. Over this passageway I have tin, bent and tacked to the floor. My hives occupy a space of two feet. My plan for wintering is to fix the inside of the hives in the usual way the Simplicity hives are fixed, and then put up boards back of the hives and fill in with dry leaves. I do not know but the glass doors might be left out. I have

not needed them yet. I am well aware that a house apiary has its disadvantages as well as advantages. The alighting-boards, and over the entrance, I have of different colors. H. S. HOXIE.

Holloway, Lenawee Co., Mich.

Very good, friend Hoxie; but I am afraid that your house-apiary, like all of those belonging to the rest of us, will in a few years be standing idle and vacant. There is one trouble with house-apiaries, that I don't exactly see how to get around; that is, that when bees get out into the room they must be got back into the hives by some means. Of course, they will go back themselves if you give them time enough, and leave the doors or windows open. If you leave the doors or windows open permanently, then you have got to sweep the floor, and keep it clear of rubbish, etc., which we don't have to do while the hives are outdoors.

IS SUGAR FROM A BUILDING THAT HAS BEEN BURNED DOWN, INJURIOUS?

Last Thursday morning there was a store containing a large quantity of granulated and maple sugar, burned in this village, and the honey-bees are there in large numbers, among the burnt and unburnt sugar, and that, or something else, has set my bees to fighting, and the question is, What effect is this sugar going to have upon the bees now, and in respect to wintering?

CAN A NUCLEUS BE FED AND CONFINED IN A WIRE-CLOTH HOUSE?

Another question is, in a nucleus swarm in a wire-cloth house, can they be fed with granulated syrup, and any kind of meal for pollen, and not be permitted to roam at large? If a colony of bees is shut up for a number of days, in case of fighting or any other cause, must they have water put into the hive? J. J. HILL.

Barton, Vermont.

Friend H., I should be afraid that the burnt sugar would give the bees dysentery as soon as they are confined to their hives. It will depend considerably upon how large a quantity they gathered, and how badly it was burned. I would examine the hives, tasting of the stores they have gathered; and if very much of it, I would lift out the combs containing it, and save them for spring feeding. We should like to have your report in the spring, as to how it turns out, in any case.—Having bees fly and take feed in confinement, is a subject that was up considerably for several years while we were practicing fertilization of queens in confinement, and also while trying to winter bees in a greenhouse. Briefly, the bees can be taught to fly around the room and go back into their hives; but a good many of them get on the glass, or against the wire cloth, and die. We have record of a few successful experiments.

SELLING HONEY AT THE COUNTY FAIR.

I attended the county fair at Valparaiso. I had a good time, stirred up the bee-men a little, and succeeded in drawing attention to the progress of the pursuit. I was surprised to find how large a number of people "used to keep bees." "The woods" seemed to be "full of them." I live some 15 miles from the fair-grounds, so I took only 250 lbs. of comb and extracted honey. I tried selling "honey on the stick," also all the extracted honey one cared

to eat, for 5 cts. I furnished crackers with the same, and met with moderate success.

The pound sections of comb honey put in the paper boxes proved to be the best-selling package. The chief obstacle to selling honey at a fair is, that people don't like to carry it around in the crowd; and when they start for home they don't think to stop for the honey. I retailed some \$10 worth on the grounds, and disposed of my remaining honey to grocers. Please report through GLEANINGS the success you met with at your county fair—the amount of honey sold, etc. I think it will be of interest to many. I distributed sample copies of GLEANINGS and price lists where I thought they would do any good. DWIGHT FURNESS.

Furnessville, Ind.

Friend F., we succeeded in selling, at our county fair, between 400 and 500 lbs. of honey, mostly in five-cent packages; but as we made only about a cent a pound on it, it did not pay us for the time and trouble, except in the way of advertising; and I consider it a good investment, for our honey trade has been considerably increased since then. Our customers seemed to prefer the glass honey-pails. We had the honey in the iron-jacket cans, and poured it into such cans or pails as they selected, just as fast, or a little faster, than it was sold. We did not try "honey on a stick," for our apiary of 200 or 300 colonies was less than a fourth of a mile away, and we feared it might create an "on-pleasantness."

SWARMING WHILE EXTRACTING.

A few days ago, during our basswood flow, while putting back the frames into the upper story on a colony from which I had just extracted the honey, a large swarm issued. I was on hand at the very beginning, and the first impression was that they had lost their queen, as they were all running hither and thither, as I have seen them doing when such was the case. But there was the difference, that all the bees were uttering the swarming-note, and soon began to pour out of the hive pell-mell. When bees get the swarming fever, it seems as if neither extracting nor any thing else would prevent them. ROBT. H. SHIPMAN.

Cannington, Ont., Canada, Aug. 3, 1885.

Friend S., I once witnessed exactly the phenomenon you mention, and the sight was a wonderful one to me; for it was almost a glimpse behind the scenes, to see just how bees manage when they start out on the "war-path," or, perhaps I should say, "secede" from their old home.

USING PLAIN SHEETS OF WAX AS A SUBSTITUTE FOR PRESSED FOUNDATION.

Perhaps it will be of interest to some of the beekeepers who are not able to buy a foundation-mill, and do not like to pay so much for having their beeswax made up, to know how we make our starters. We do not use full sheets of foundation in our apiary. I put the big dish-pan on top of the stove, with about two gallons of boiling water. Add the beeswax, but do not let it get very hot—just so it is melted.

Have a pail full of very cold water, on a chair near the stove. Take a piece of glass the length you want your starters; dip the glass in the water and then in the wax, and back in the water very quickly. If you are quick enough, the wax will

leave the glass, which must be clean and cold. You cut the strips just as wide as you like, and they are ready for use. The bees will work on them just as well as if they were pressed. We have used them for two years.

We have 50 colonies of black and albino bees. Our bees are doing better now than they have all summer. We have sold only about 200 lbs. of comb and extracted honey. MRS. ALMIRA HAZEN.

Pleasant Mound, Ill., Aug. 29, 1885.

Thank you, my friend; but the idea of plain wax sheets, made by dipping on glass, is very old. In our early volumes the matter was considerably discussed; and although it will answer tolerably, plain sheets were soon laid aside for regular foundation. We think if you will try these sheets, however, by the side of well-made foundation, you will notice quite a difference. They are also more expensive, because they contain more wax to the square foot.

SOME QUERIES IN REGARD TO BASSWOOD-TREES.

Will you please answer the following questions?

1. How many years are required from the time basswood seed is planted, till bees begin to work on its blossoms?

Ten or fifteen years.

2. How many years' start would one have by purchasing trees of you which are 10 ft. high, in preference to seed?

Five to ten.

3. How many trees are required to keep 100 colonies busy?

Can't answer; perhaps 100 large trees.

4. How many should be placed on an acre?

It does not matter much. We have 4000 on 10 acres. See A B C.

Cokeville, Uintah Co., Wyo. CHAS. F. CLARK.

MORE ABOUT BORROWING TOOLS; A BUZZ-SAW OUT OF AN OLD FANNING-MILL—HOW TO CONSTRUCT.

While reading GLEANINGS I was very much pleased in the way you express yourself in regard to borrowing and lending tools, and would say that I have been annoyed that way myself. Although a person may have to borrow sometimes, as a rule it can be avoided; but I think your article is to the point, and I would advise every reader of GLEANINGS to read it carefully, and act upon it, for it will save hard feelings among neighbors. But I say, if neighbors must borrow from one another it would be best to take the best possible care of what they borrow, and they would then feel more like lending to one another again.

As I intended to give a description of my circular saw that I made for sawing hive-stuff, I will now proceed to do so. I made the frame the same as any circular-saw frame, with tilting table; but having an old fanning-mill gearing I attached it to one side of the frame, to connect with a shaft under it; and on this shaft I put a belt-wheel 18 inches in diameter, with 1½-inch flat belt running to the saw-mandrel. I turned my mandrel and shaft, and made the whole machine myself, and it cost me but little outside of my own labor. I use a 5-inch saw, and turn and feed myself, and can tell just how fast to feed, to correspond with the power. It is a very handy saw to have, to do odd jobs with, even if you have a power saw. I sawed some nice sec-

tions from green frozen poplar, which are as white as snow. They are not so white when sawed out of seasoned lumber. R. B. KIDDER.

Columbus, Wis.

Thanks, friend K., for the suggestion you give in regard to the hand-power buzz-saw. I believe this is the first time the idea has come up, of turning the saw with one hand, and feeding it with the other; but I have no doubt it can be done, and that such a machine would be a great help in many instances.

WINTERING ON COMBS WHERE THE OLD BOX HIVE, UNPROTECTED, CAME OUT AHEAD.

For the first time I say, "How do you do?" I have just finished reading GLEANINGS for Oct. 1st, and could not do without it now. I am a young hand at the bee-business. I can get along in summer, but the winters are hard. I have had bees for three summers only. I commenced on a small scale, and am still working on the "small." Last fall we had built up to 11 colonies, but saved only one. It was in an old box hive, and stood out all winter with no protection. The others I moved to a shed. We had a splendid white-clover honey-flow and a light flow from goldenrod and Spanish needles. I now have four colonies. They have 50 or 60 lbs. of surplus in 12-pound boxes. How would it do to leave one of those boxes over each colony for winter? Would they take it down into the brood-chamber if they needed it? M. L. BREWER.

Philo, Ills., Oct. 12, 1885.

Friend B., I think your old box hive probably had old and tough combs, besides being well ventilated. The rest were probably on new combs, and may be not very strong at that. And then on top of it all, you put them in a shed where they probably failed to receive the benefit of the sun's rays. Leaving honey-boxes over the colony, so as to form an air-space for protection from the frost, was advocated considerably some years ago; and in our back volumes you will find a multitude of reports.

"A FISH-STORY"—WHEW!

As you are interested in carp culture, I clip the inclosed from our local paper. I am satisfied the information will be valuable to all who are interested in the carp industry. S. M. PEACOCK.

Lancaster, Ky.

Mr. Jesse Doty relates the following singular occurrence. Mr. Doty is reliable, and no question can be raised as to the correctness of the account: On the farm of William Hiatt, near Hyattsville, in this county, is a large pond, which was, a few years ago, well stocked with German carp. One day last week Mr. Doty went over to this pond to shoot some of the fish. He took his station on the east side of the pond, and soon killed several very fine ones as they came to the surface to sun themselves. The weapon used was a double-barreled shot-gun. After some five or six shots were fired, Mr. Doty noticed a singular agitation of the water on the west side of the pond where there is a slight drain. This agitation finally grew to be a terrible commotion, and Mr. Doty hastened to that side to see what was the matter. He discovered that a panic, caused no doubt by the shooting, had seized the fish, and they were forsaking the pond in large numbers by way of the drain mentioned. That drain extended for only a short distance, and there the fishes actually pursued their way across the grass, their noses stuck straight toward the woods. Mr. Doty ran around in front of them, and after much difficulty succeeded in heading them off and driving them back into the pond. He says there were no less

than 250 carp, varying in size from one to three feet in length that were attempting to effect their escape. Mr. Doty warns all farmers having ponds containing carp not to shoot into the water, since he believes it will surely result in the fishes abandoning their home. He says he was greatly astonished at the ease and celerity with which these fish moved along on dry land.

Friend P., your story is a "fish story," without any mistake, but I think there is something of value to be gathered from it, after all. It is doubtless exaggerated, about as newspapers often do exaggerate; but from my own observation I am satisfied that carp may be frightened so as to be put into a panic, and I think it is likely, under some circumstances, they may desert the water and get out upon the ground, may be some little distance, especially if the ground is wet and marshy. I told you, a few months ago, how greatly astonished I was to see a great fish make his way over the ground near the edge of our pond, with apparently no very great difficulty. Mr. Peirce, in our carp-book, warns us against frightening carp in drawing off the pond, lest they bury themselves in the mud to such a depth they may never get out.

WHAT MAKE OF PERFORATED ZINC EXCLUDES QUEENS?

On page 516 of Aug. 1st GLEANINGS you ask if it is the D. A. Jones make of perforated zinc that has successfully restrained the queens. I suppose that it is, as I ordered the zinc of you some 18 months ago, and understood it was Mr. Jones's make; at all events, it is just *right*, as I have never yet in a single instance known a *queen* to get through, and this is my second season to use it.

Instead of using a full-sized sheet of the zinc to cover the whole top of the hive, I use a wide strip of enameled cloth across the center of the hive, of sufficient width to require only 5-in. strips of zinc at each end of the frames, being careful to lap the zinc $\frac{1}{2}$ inch or more on to the cloth. Having used 30 hives this season for both extracted and comb honey in this way, I have not had a queen go above; and in case of necessity in opening a brood-nest, the two strips and the enameled cloth are much easier to remove and replace than the full sheet, besides the *economy* in using the zinc.

I have no fears of losing a swarm *now* while off to meeting or Sunday-school. On Saturday eve I go around to all the *strong* colonies that are at all *likely* to swarm, and adjust a queen-guard to each entrance, and then we *all* go to meeting with as much assurance of saving our swarms as if we stayed and watched them. In only *one* instance have I lost a swarm by being off to meeting, and in that single case I found that I had not fastened the guard properly, so that the force of the swarm issuing moved it away from the hive, when, of course, the queen got out. D. E. BRUBAKER.

Maxwell, Ia., Aug. 4, 1885.

Thanks, friend B., for your report. The zinc you mention was neither the American zinc nor that furnished by D. A. Jones, if I am correct, but some that we imported from England. We have recently received a communication from friend Alley, who has, perhaps, had more experience with drone-traps than any of us, and he is quite emphatic in favor of the imported zinc, although there is but a minute fraction of difference

between it and the Jones zinc, in regard to the size of perforations. We are just now making preparations for making machinery for perforating in our own country, that we may be enabled to save the amount that we have heretofore been obliged to pay in the way of duties and transportation.—I am very glad indeed if any arrangement can be contrived, so that none will have to be absent from church or Sunday-school on account of bees.

A BEGINNER'S EXPERIENCE, WHO LIVES NEAR GEORGE E. HILTON.

I began the bee business by purchasing two colonies of black bees last fall, for which I paid four dollars each; and with the advice and showing of the man I bought of I built two hives to winter them in. They were in Langstroth frames, ten frames to the hive. I built another hive, 3 inches larger, and packed the space with fine dry sawdust, and let the outside hive come up about 10 inches above the inside one, and covered the frames with a cloth, and then put in about a bushel of fine dry sawdust on top of them, and left them standing out, exposed to all the cold of last winter; and I tell you it was the most severe weather ever known here. But my bees came out all right this spring, so I bought seven more. They had been wintered in a cellar, and seemed all right; but before I was aware of it one stand was robbed out by the others. Then I contracted the entrance of the hive, and had no more trouble of that kind. They were all in single-walled hives, so I made all new hives. I now make my outer hives large enough to take about four inches of packing, and am filling them with fine dry pine sawdust. I have now 18 colonies, all very strong. I have taken off about 350 lbs. of comb honey in 1 and $\frac{1}{2}$ lb. sections; and right here comes a question I should like to have you answer.

WHY DO MY BEES CLUSTER OUT?

I made my inside hives to take the Langstroth frame, eight to the hive, or 12 inches wide, according to the recommendation of an apiarist near me who has a large apiary. He told me that 12 inches is better than 15 for wintering; but yesterday I found a set of boxes filled by a young colony, and I took them off, placing the enameled cloth on top of the frames. The bees went in large numbers out on the outside of the hive, and stayed there all night. To-day it has been raining incessantly, and still they are on the outside, in the rain. About 4 p. m. I looked into the hive, raised the cloth, and it seemed to be perfectly full of bees. The question with me is, Is there not room for them all in the hive? For fear there is not, I have placed a set of empty sections on top again; yet if there is not room for them in the hive, how shall I winter them? One new colony made and finished 70 lbs. of fine comb honey in 35 days, and have 30 lbs. more about ready to cap. That is doing very well, I think. I intend to winter them on their summer stands. They were all black bees, but I have introduced two queen-cells and two virgin Italian queens, from the apiary of G. E. Hilton, near me. I did according to his directions; that is, when a new colony came out I let a virgin queen run into the old hive. Was that right, and will it succeed?

HOW TO DETERMINE WHEN A COLONY HAS WINTER STORES ENOUGH.

Please tell me how you determine whether there is enough honey in a hive to safely winter. Do you

weigh the frames with the bees on them, or how do you determine? You see, I know but very little about the business, and want to learn. I know you will say, "Get the A B C book," and I am going to as soon as I can; but all in good time.

H. B. CAMERON.

Newaygo, Newaygo Co., Mich., Aug. 2, 1885.

Friend C., it is quite common for bees to cluster out in large numbers, after removing their surplus receptacles. We usually put on an empty upper story, or an upper story filled with combs. They will do no harm by clustering on the outside of the hive, unless some of them are killed by a cold storm. I have known this to happen several times late in the fall. They usually go in the hive, however, as soon as we have a few frosty nights, and I think you will find there will be none too many bees to winter nicely, if you give them good heavy combs full of stores, in proportion to the number. I would, however, leave the winter brood-nest larger than usual for so heavy a colony, although I have never seen the colony that required more than the space occupied by ten L. frames.—Your question about determining when a colony has winter stores enough is answered by friend Doolittle, on another page, fully as well as I could answer it myself.—So you are a neighbor, are you, of our friend George E. Hilton, whose apia-ry we have so recently had the pleasure of looking at?

BAD ODOR FROM THE HIVES; WHAT CAUSES IT?

The bees seem to find something here that gives a sour smell to their hives. Sometimes you can notice it ten or fifteen feet away. Can you tell me what it is? They seem to be doing well, though. The frost has held off. The nearest it came to one was Sept. 23. The mercury fell to 39 degrees; but now, Sept. 27, we are having hot summer weather, and the bees are improving their time.

G. SCOFIELD.

Ridgeway, Orleans Co., N. Y., 1885.

Friend S. I have noticed something like what you describe, during the fall of the year, when the bees are working on certain kinds of autumn flowers: but I can not tell you what flowers. Perhaps some of our readers can help us.

WAS IT CARELESSNESS, OR THE FAULT OF THE BEES THAT RESULTED IN THE DEATH OF THE QUEEN?

The queen you mailed me on the 23d of July was received all right; but as my bees behaved badly and killed her, I will tell you the circumstances.

I wished to put the queen in a hive where the old queen seemed to be on the decline. I removed the old queen and put the new one in the hive, according to directions. At the end of two days I released her on top of the frames. She flew, and I thought I had lost her; but on looking through the hive, in a little while I found her balled. I caged her again, and left her in the hive two days more, when I again released her. She ran down into the hive. I immediately commenced searching for her, and in a few moments I found a bunch of bees, nearly as large as a goose-egg; and when I got them out of the hive, and separated, the queen was dead. On the second day after the queen was put in the hive, I cut out about twenty queen-cells, and on the fourth day about ten; to-day, 10 days after, I removed ten more. I expect now to give them a cell form-

ed on brood taken from a queen which I purchased of you in June. I should like to know if the fault was my own, or were the bees simply determined to raise their own queen?

O. P. PHILLIPS.

Amo, Ind., Aug. 3, 1885.

Friend P., the behavior of the bees would indicate to me pretty clearly that they had some sort of a queen already, were it not for the fact that they started so many queen-cells as soon as the queen was dead. I suppose we shall have to explain it by calling it one of those exceptional cases where a colony refuses to accept any queen.

MORE ABOUT SWEET CLOVER AS A HONEY-PLANT.

In your foot notes on my article on sweet clover you say, "But 1000 lbs. from one acre during four weeks seems to me almost incredible."

It does seem like a great amount, yet I know I got over 500 lbs. of surplus, or box honey, during the sweet-clover flow, and I believe 35 to 45 colonies would store in brood-frames, and use in breeding, during 4 weeks, not less than 500 lbs. What do you think they would use? Of course, that part of it is guesswork with me.

The spider plant may drip with honey, and yet not produce one-fourth the amount of honey that sweet clover would, for two reasons. First, the clover secretes honey all day long; the bees may visit each blossom a hundred times a day, and get a small amount of honey each time, while the spider plant is open only a short time. Second, the clover would produce perhaps a thousand times as many blossoms on the same amount of ground as would the spider plant. My clover grew from 5 to 7 feet high.

As to bees getting honey from other sources than sweet clover during the time, I would say that other bees within two or three miles of me gathered no honey during the same time. I can not believe my bees gathered from any other source than sweet clover.

E. W. FITZER.

Hillsdale, Mills Co., Ia., Oct. 7, 1885.

Friend P., very likely it may be a hard thing to tell where the honey did come from; but I hope you will excuse me for still feeling quite certain that such a quantity could not have come from the area of sweet clover you mention. We have had tolerably heavy flows of honey, when we could not find *any* thing that seemed to justify the amount that came into the hives daily.

MORE IN REGARD TO RASPBERRIES AS A HONEY-PLANT.

I have just been reading the articles on raspberries, in August GLEANINGS, and will give you our experience. I consider raspberries our only reliable source for light honey. Last year the colonies which were strong enough for boxes at the beginning of raspberry-bloom commenced on every box, but the bloom ended when only a few were capped. The others remained in that unfinished condition from week to week, although the fields and roadsides were white with clover-bloom. I have now taken off all the light honey we expect to have, 214 lbs., about half comb and half extracted, from eight colonies. This is all amber colored, and I think it is mostly from raspberries, though there has been some clover honey this season.

The Turner does not do with us as described on p. 530 of GLEANINGS, but it is one of the earliest, and is good. The Philadelphia yields much better, and I

think it furnishes more honey. The Cuthbert is later, and very good, but it does not yield very well with us. One of the first and best for honey is the Purple Cane, but it is not good for market. The bees work on the black as well as on the red.

I can not agree with Mrs. Chaddock. I wish to have religion the chief business of my life. I leave my bees to swarm naturally through the week if they will. If I think any of them likely to swarm on Sunday I swarm them artificially on Saturday, or take the risk of losing them. If you do not wish to have them swarm at all, give them plenty of room.

MISS L. WILLIAMS, 9-11.

Delavan, Wis., Aug. 5, 1885.

Thank you, my friend, for your report in regard to the different kinds of raspberries. If we could get at the kind of raspberries most profitable for bee-keepers in different localities, and during average seasons, it would be quite a valuable fact.

THE NEW JOHNSTON PUMP: HOW LONG DOES IT TAKE TO EMPTY A PAIL?

October GLEANINGS, page 667, that Johnston pump. About what is its time in using up a pail of water? The continuous stream is a great improvement, I think. I should like one or two before swarming-time again. I have no report to make. I had 10 hives last spring; obtained 100 lbs. of honey—about 300 of it comb honey; increased to 46 hives. In this community we have no basswood, no white clover, no buckwheat. Honey this season from the middle of August to the 26th of Sept., mostly from smartweed and asters.

El Dorado, Kan., Oct. 12, 1885. R. W. PERKINS.

The Johnston pump, as sent out by the manufacturers, will empty an ordinary pail of water in two minutes, and will send a constant stream 50 ft. and over. If, however, the orifice is reamed out with an awl so that the opening is a little larger than $\frac{1}{4}$ in., you can empty a pail in about a minute, at the same time forcing the stream just as far as before. In this case, however, the stream will not be as constant as when the orifice is smaller. We will send out the pumps unchanged, and the purchaser can easily make the orifice to suit himself.

THAT CRYSTALLIZED HONEY-DEW.

The following should have been used some little time ago. It is in regard to the crystallized honey-dew mentioned on page 586. We sent it to Prof. Devol, with directions to forward to Prof. Cook, after he had examined it. Friend Cook's reply appeared on page 626.

I did not stop to make a microscopical examination of the "crystallized honey-dew" on those plants, but mailed them immediately to Prof. Cook. I think the amount of honey-dew present on those specimens something remarkable—much more than I had ever before seen. It hardly seems possible that it could be produced in such quantities; but it is there; and how else is its presence to be accounted for, if not from the insects?

Columbus, Ohio, Aug. 27, 1885. W. S. DEVOL.

GRAPE SUGAR FOR WINTER STORES.

A few years ago you recommended grape sugar as a good article to feed early in the spring, to stimulate bees to breeding. I tried it, and found it to be the very thing. I should be much obliged if

you would let me know if it would do well to feed now for wintering bees on. We have had such a drought that my bees have nothing to live over winter on, and I should like to feed grape sugar if it will answer the purpose. Please let me know, and also if you have the grape sugar for sale, and at what price.

My bees might have half enough honey to winter on. If I were to feed half as much as they would want of grape sugar, would they use the grape sugar first, as it was gathered last, or not? If they would use it first, it would not get hard before they would use it, and would answer their purpose. Did you ever feed it for winter stores?

G. W. ROSENBERGER.

New Market, Va., Oct. 1, 1885.

Friend R., although grape sugar has been used for wintering, and sometimes successfully, I would not advise using it at all at this season of the year. We have not sold it for several years, even for spring feeding, because the low price of cane sugar would make it no object. The bees might use the grape sugar first, although they greatly prefer good honey when they can get it, as you may have noticed. But even if they would take it first, I think I should prefer to invest the same amount of money in coffee A sugar, which can now be had by the barrel for only 7 cents per lb. Grape sugar always hardens in the cells in cold weather, which is the principal objection we have found to a good article. I am sorry to say that some of the factories that started up a few years ago turned out an article so poor that it was unfit for bees or for any other purpose. This latter reason, in connection with the recent low prices of cane sugar, is probably why it has been almost of not entirely discarded for feeding bees.

SUNFLOWERS: A REPORT OF.

I got a nice lot of sunflowers from the seed you sent me, but the bees did not work very much on them; but the seed will pay me for my trouble. As to the spider and Simpson honey-plants, I never got any of them to come up.

JOHN MOTE.

Jenkins, Ala., Sept. 18, 1885.

Friend M., it is a little remarkable that bees sometimes work on sunflowers, and again they do not. I do not know whether it is because it is only occasionally there is honey in the blossoms, or whether the bees never work on sunflowers at all, unless they are obliged to.—In regard to the seeds of the spider and Simpson plants, I think you will get the seeds to germinate every time, if you follow the directions given in our price list. For next season's use we shall have these directions very plainly printed on the wrapper. We mail you a package of each, free of charge.

WILL IT DO TO USE STORES FOR WINTER, SAVED OVER FROM BEES THAT DIED THE WINTER BEFORE?

Last fall I had 6 swarms of bees. I fed them sugar syrup till they were well filled, and then put them in the cellar. Three of them were dead in the spring, and the rest died of spring dwindling. There is a lot of the stores left. What shall I do with it? Will it do to feed bees yet when they can fly, or not? Would it be wise to melt the combs all up and make wax? The hives are in the barn, with the frames in them. I have not seen them since the fore part of

the summer. The mice will be apt to trouble them through the winter.

Mrs. F. L. Church.

Mitchell, Mich., Sept. 30, 1885.

My friend, if the stores are principally sugar syrup which you fed, I should feel quite sure it would be just as good for next winter as any you can use, providing the bees sealed up the sugar at the time it was fed to them. If there are unsealed stores in the combs, or any thing that is thin and watery, I would throw it out with the extractor. I would give the combs to the bees as soon as possible; and if I could I would put one comb at a time in the center of a strong colony, to let them sweeten and repair up before winter. I should never think of melting up good combs, especially where they contain stores.

GIVING BEES FOR WINTER STORES, HONEY THAT HAS BEEN SCORCHED.

We have several pounds of honey, obtained in rendering cappings into wax, which was scorched until it looks, tastes, and smells much like dark molasses. Would this be wholesome for winter stores, either alone, or used with syrup, as in making the Doolittle bee-feed? CORNELIA B. KILBOURNE.

Clinton, Oneida Co., N. Y., Oct. 7, 1885.

My friend, I would not give it to the bees this fall. Save it until they can fly next spring, and it will do no harm. We think you must have been a little careless in getting it scorched, for we usually get the very nicest quality of extracted honey from cappings. It might do to mix with syrup in making the Doolittle bee-feed, but I should be pretty careful about taking any slight risk in regard to the quality of the winter stores.

SAMPLES OF HONEY FOR OUR APPROVAL.

I send you to-day two 7-lb. pails of honey. The pail not candied was thrown out yesterday. There is a little basswood in it, but I do not know what the rest of it is. You can give me credit, in proportion as it compares with that of Heddon's. Honey is not as good in quality this year as we have had, but it is better than last. There may be some specks of comb in the honey, as I never use a strainer, for the reason that it will not run through the thinnest cloth unless you heat it hot. I have some five or six thousand pounds like the sample sent.

Springboro, Pa., Sept. 24, 1885. CHAS. OLIVER.

Friend O., the two pails came to hand in perfect order, and the honey is nearly if not quite equal to any we have ever had. It is remarkably thick, and nicely ripened, and should command a good price in any market. These pails make a neat and handy package indeed; and if the railroad men could be induced to handle the box without tipping it over, the honey is so thick it seems to me as if it might be shipped safely, without any sealing up.

BLACK WORKERS FROM IMPORTED QUEENS.

Why is it that imported queens' daughters sometimes produce some black workers with no perceptible yellow bands, while the improved Italian tested queens' daughters never do? at least, they never have for me. I have raised about a hundred queens this season, and a few of the daughters of my imported queen produced some workers with no bands. I commenced four years ago with six hives; have now 84 strong colonies, and 15 three-frame nuclei of

nice Italians, and \$200 ahead for my trouble and expense. How do you think that will do for Blasted Hopes? I do not count on losing one this winter. I expect to winter my nuclei where they stand now, and perhaps I shall have queens to replace any that may die in my strong hives during the winter.

W. A. SANDERS.

Oak Bower, Hart Co., Ga., Oct. 5, 1885.

Friend S., I do not know that we have ever seen bees all black, right from the daughter of any of our imported queens, although we do have bees with yellow of such a dark leather shade that the bands can hardly be recognized unless the bee were to be filled with honey, and placed on a window as per A B C. There is this about the yellow bands, however: By breeding for bands for several generations, this feature becomes so prominent that a first cross with common bees will pass very well for full bloods, so far as the marking is concerned. Imported stock from Italy has not, of course, been bred for color or for bands, as we breed them here.—I do not see how you can consistently have a place in Blasted Hopes, friend S.

BURYING BEES FOR WINTER.

How will this do? On dry sandy land we excavate, say a foot deep, lay timbers so the bottom of hives will be 4 or 6 inches from the ground; set stakes at sides of ends, and board up a space, sides and top, of 6 or 8 inches; bank up sides and ends with earth; cover over with oat straw. We have about 15 hives for wintering.

J. B. WHITAKER.

Hopkinton, Iowa, Sept. 29, 1885.

Friend W., this subject has been pretty well discussed in our back numbers. With such winters as you have in Iowa, no doubt it will sometimes answer a good purpose; but as a rule I am not much in favor of burying bees. The articles of W. Z. Hutchinson, for several years back, have discussed this matter of burying bees, in all its bearings. May be he can answer your question better than I can.

LETTING THE SNOW DRIFT OVER THE HIVES IN WINTER.

I find nothing in the A B C as to the elevation of the hive in wintering. If you allow the hive to remain on the summer stands, the first deep snow would smother them, closing up the entrance. Have you a device to admit the air, or what is your plan? I have prepared my bees according to your instructions, in a Simplicity hive I got from you last spring, leaving the hive extending over the bottom-board about 1½ inch, and it is only about 6 inches from the level of the ground.

H. R. STEINBUCK.

Eagleville, Pa., Oct. 5, 1885.

Friend S., I think you are decidedly mistaken in saying that the snow would smother the bees. I have not been able to discover that the bees ever smother by being covered up with snow; in fact, I should rather have them covered with snow than to be prepared in any other way that I know of, providing the snow falls itself, or is drifted on to the hive by the wind. Your Simplicity hive is all right as it is, if you are going to risk wintering in such a hive; but you will notice, by our price list and A B C book, we do not recommend these hives for winter purposes.

FATTENING-BOATS OR TANKS, FOR CARP.

Occasional inquiries come to hand from the readers of the A B C of Carp Culture. Lately, several of these inquiries are concerning the illustration on page 69 of that work. I can now see that further details are necessary. I find it impossible to get ready-made screen material for the bottom of the tank or boat, which is of sufficiently fine mesh, that is not at the same time of too light wire. I have persuaded one of the oldest manufacturers here to make up a small lot, of extra-heavy wire. I also find that the mesh of the wire netting on top of the boat had better not be larger than $1\frac{1}{2}$ or even $1\frac{3}{4}$ inch, because the carp dislike close confinement; and if the mesh is from 2 to 3 inches they are liable to force their noses through, even until they "gill" themselves. A mesh of $1\frac{1}{4}$ inches is sufficiently large to pass the food through. I find the ready-made netting is also of too light wire, and have also made arrangements to have some made of heavier wire. This material will be heavily galvanized. It will at present cost here, for the top, \$1.75 per square yard; and for the bottom, \$2.50 per square yard. It will be made 36 inches wide. It is just as well, if not better, to make the ends of these tanks square. I have for many years used exclusively, for fastening screens, the carpet staples illustrated on page 698 of GLEANINGS.

The fall drainings of the leading carp-cultural establishments in this region (and owned by members of the American Carp-Cultural Association elsewhere), are mostly finished, and the most satisfactory results are reported wherever the improved plans are in use, while failures are generally reported with chance-made ponds. We have had several notable carp dinners in this region, and every participant pronounces the carp a first-class food fish. Most of the carp in this region are of the parti-scale types, and a large percentage are nearly scaleless.

Every carp culturist in the country should join the American Carp-Cultural Association. It costs but one dollar. I will cheerfully send constitution and by-laws to any address. MILTON P. PEIRCE.

Philadelphia, Pa., Oct. 20, 1885.

Thanks, friend P. Our wire-cloth factory have furnished us steel wire cloth as fine as 8 meshes to the inch, and heavily galvanized, and it seems to me it is strong enough to hold a horse. Prices are given on another page. We mail you a sample, to let you see if it will not be the thing for the bottom of the fattening-boats. I also send you a dollar, that I may become a member of the American Carp-Cultural Association.

BEES AND CIDER-MILLS.

I believe those who would petition legislation in regard to cider-mills, as per your editorial, are just as ignorant of other people's industries as others are of bee culture; for the bees are just as much a nuisance to the cider-maker as the cider-mills are to the bees. When both parties have a proper understanding of the matter, it can be fixed at little expense, so the cider-maker is not bothered with bees, and the bees are not hurt by the cider. A press generally has a roof, and a little more expense will put wire cloth over a part, or mosquito-bar, if not boards, and it will pay, besides keeping bees out. The doors want good strong springs to them and they should be so fixed that they can not be propped open. We have a press only a few rods

from the apiary, and we kept the bees out by having only the main places closed; but this fall we were compelled to close every hole, for they found almost every one they could get through.

THE LINDEN FOR HIGHWAY PLANTING.

While so many varieties of trees are lauded for highway planting, the basswood receives scarcely a good word. One defect, and the only one I know of, is that it is late in emitting its foliage, which I think is counterbalanced by that sweet perfume and merry hum later on. Bee-keepers would do a grand thing by furnishing the trees free to the farmers who plant them. The old fences can be taken away, the ground planted to potatoes, and then basswood planted instead of every post. Soon the wires can be attached to the trees, if a fence is desired, and some locust can be mixed in, as they make splendid posts. There should be some trees near any apiary, for they come when most needed. Here let me speak a good word for the ground-ivy, or gill-over-the-ground. I think the honey is splendid, and I judge it is good for medical purposes.

Marshallville, O.

C. WECKESSER.

CAN A CORN-HOUSE BE CONVERTED INTO A SUITABLE WINTERING HOUSE?

Last spring I bought three colonies in chaff hives. I have now ten, all told. To winter the same I thought of covering my frame corn-house, 12x16 ft., with matched pine to make it dry and warm as any out-building. I have asked other bee-men about it, and they say a building to keep bees in must be frost-proof. What say you?

Plymouth, Mich.

O. ARCHER.

Friend A., a corn-house would not be suitable, without very much expense being laid out upon it, for a wintering-house. Houses of this kind are usually made either close to the ground or partly under the ground; or, what is better, is a cellar under a building, so as to get protection from the frost. Are you really sure that a wintering-house is needed in your locality? I certainly would not go to the expense of building one, unless extensive bee-keepers in your vicinity have found them an object. I believe that cellars are, as a general thing, cheaper and better.

HOW TO PUT THE HILL DEVICE OVER THE COMBS.

I take this method of asking which way you place the Hill device over the frames of a Langstroth hive. I looked at the device you sent me, and was not sure which way they ought to be put on the frames of comb—the back-bone (hoop iron) across the frames of comb, or lengthwise of the comb. If I put it lengthwise of the comb, the space under the burlap does not extend near the sides of the hive. When full with ten combs, the burlap fitting close might prevent the bees from getting to the outer combs. If I set the back-bone across the combs, the burlap does not fit so well at the ends of the hoop iron, or back-bone. The space under the device is only across the combs, and not as long lengthwise of the combs as it would be to set it the other way. Which way should the back-bone of the device be set—across the combs, or lengthwise of the combs?

JOHN M. LEWIS.

Crothersville, Jackson Co., Ind., Oct. 12, 1885.

Friend L., the device is placed over the combs so that the piece of strap iron runs parallel with the brood-frames; that is, when it is intended to be used with the Simplicity

hive; but with the Gallup frame, or Adair, it might be best to turn it the other way. In any case, the device should always be placed exactly over the center of the brood-nest; and the cushions or chaff should come down close all around.

HOW TO PREVENT WEEDS GROWING AT THE ENTRANCE.

Your piece in regard to weeds in the apiary reminded me that perhaps the way I manage my yard may be interesting to some of your readers. It is considerable work on the start; but as it is very lasting, I think it pays. I dig out a space $3\frac{1}{2}$ feet square, and six or eight inches deep, and fill with coal cinders, pounding them down as solid as possible. No grass or weeds ever find their way through. Making the holes $3\frac{1}{2}$ feet square, leaves room enough around the hive for the lawn-mower to work without touching it. A yard kept in this way presents a very tidy appearance. I find very few yards among our bee-keepers but are rather slovenly looking, and I think a little stirring up of this matter, with a few directions how to fix up a little, will have a tendency toward a great improvement. I believe keeping one's yard nice and tidy helps to sell its products; consequently I look at it as a paying investment, and, like yourself, I can not tolerate the stone on the hive nor the rough casing around it. If the business won't pay the expense of planing and paint, I for one will abandon it and try something that will.

M. H. HUNT.

Jell Branch, Mich., Oct. 21, 1885.

I would say to our readers, that friend Hunt is a man who is very particular about the tidy appearance of his apiary. I have visited both his bee-yards, and can speak from actual observation. We have used cinders around our hives in the way Mr. H. suggests; but in our experience, weeds and grasses will, after a while, creep over from the sides, if not through the cinders. For this reason, and the expense, we prefer using salt, and then have white sand in front of the entrance. I like to watch the yellow-banded Italians sporting on a light background. Of course, the sand can be put over the cinders, if desired.

ERNEST R. ROOT.

SALT AROUND THE ENTRANCES, ETC.

GLEANINGS for Oct. 15 is at hand on time. I was glad to see that note of Ernest's in regard to killing weeds with salt. I have used it with success for two years. It is the only thing I can find to kill coco grass. If any of the friends are bothered with that grass, one or two applications will clean it up.

I send in my first report. This is my second year in apiculture. I have invested to the tune of \$125.00. I started last spring with 6, increased to 21. I have taken only 125 lbs. of comb honey in 1-lb. sections. But every one of the 21 has ten frames of brood and honey, to carry them over the winter.

While I can not write and tell you that I have ceased to use tobacco, I can say that I have five brothers, and none of us ever used it or whisky either. I hope to send you a better report next year than this.

C. E. JENKINS.

Bryan, Texas, Oct. 19, 1885.

OBTAINING NAMES AND ADDRESSES FROM THE PAGES OF GLEANINGS.

When reading GLEANINGS I sometimes feel like sending a circular to some of the friends, but do not feel like doing so without your permission; and the fact is, I did send some before it ever occurred to

me that "I have no earthly right to use them," because you paid for getting them, and not I. I beg pardon for having done so, and am willing to pay you what you think right, in strawberry-plants next spring. As you request the reports from those who have used the reversing devices, I should say I am well pleased with them. They do not cut the fingers as the metal corners do, and are just as good in every way, and better in several ways, aside from their reversing advantages.

You advise "full frames of honey" for winter stores. I always think they winter better when only three-fourths full. When full it acts too much like a cake of ice, or a board. The cluster on each side is too much for itself.

C. WICKESSER.

Marshallville, Ohio, Oct. 12, 1885.

Why, friend W., you surprise me. Gather up the names in GLEANINGS for the addresses of persons to whom to send price lists, by all means. In fact, that is just what I want the bee-friends to do, that we may get still better acquainted. One reason why I insist on having every name with the full postoffice address is because I want you to send circulars in this way. It is true, that names thus obtained may be used for the purpose of sending swindling advertisements and circulars; but to counteract this objection to giving names in full, we are going to try to keep our readers posted in regard to all fraudulent circulars they may receive.

WINTERING IN A CAVE: QUESTIONS CONCERNING.

Will you please answer, through GLEANINGS, a few questions? On account of the winter being so very severe upon the bees, I concluded to winter them this coming winter in a cave, so I have commenced, and it is about half dug. Yesterday I took hold of your A B C, and found, under the head of "Wintering," that you "would not try indoor wintering with less than 40 or 50 stands." I have 21 stands of bees. I thought to place 12 of them in the cave. Now the question arises in my mind, Are you still of the same opinion? and if the cave is frost-proof, why won't it do with few stands, as well as with many? The cave being in the earth, of course it will be a little damp, if the hives are kept from coming in close contact with the damp, either on side or floor or ground. I will have a good drain, sufficiently large to ventilate the cave, and it will run some forty or more feet under ground. Do you think it will be sufficiently dry? I will have the bottom of it so dug that it will thoroughly drain itself. It is dug 8×10 ft., $5\frac{1}{2}$ ft. to $6\frac{1}{2}$ ft. deep. It will have two doors. It will oblige me if you will please tell me a little in regard to wintering in a cave. I will have a boxing, or a pipe like a chimney, so a current of air can pass through.

There may be quite a number who would like it if you would give us a little instruction in this direction. Again, if burying bees is a good plan, how is it that they won't do in a cave, if properly ventilated?

The honey season is good so far, and the present rains promise full honey unless we get too much. No honey-dew. Those that wintered in cellars and caves were the only ones who brought their bees out without heavy loss, and in many instances they died right out without a bee left.

Cleveland, Iowa.

EVAN B. MORGAN.

The cave as you describe it, friend M., will

answer excellently, especially if you manage to shut out every particle of light: and there is this in your favor—such caves have been successful in very many localities. If your cave is absolutely frost-proof, very likely ten or twelve colonies will do as well as a larger number. Your cave needs to be proof against warm spells that may come in winter, as well as against extremely cold spells: that is, the temperature should never go down to freezing nor up as high as 60°. Some claim, you know, that the temperature ought not to go as high as 50°.

THAT NAMELESS BEE-DISEASE! DOES REMOVING THE QUEEN EFFECT A CURE?

Your foot-notes to C. K. Decker, p. 677, Oct. 1, on "That Bee-Disease," carries the idea that the trouble is in the queen; but in one instance I find it is not so. I had, last summer, a stand dying about as Ernest and Mr. Decker and some others have described. August 13th the queen went out with a swarm. She was hived on empty combs, and no more of them died. A vigorous young laying queen was introduced in the parent hive, but bees from it kept dying for some weeks, until after I took some of the outside combs of honey out, putting empty ones in center of the hive, then all got well soon. Is it not possible that they had some bad honey, which may have caused the dying in my case?

I hope to have one or two hives affected in the same way next year, so that I may learn the cause.

R. W. PERKINS.

El Dorado, Butler Co., Kan., Oct. 12, 1885.

Friend P., I think it very likely that unwholesome stores are frequently the cause of this malady, or something quite similar to it. In that case, of course, putting in a new queen would not help the matter; but it would probably correct itself if the bees survive long enough to consume all the unwholesome stores.

ANOTHER SWARM EXTRACTOR: HOW TO CONSTRUCT.

I sent to you and got a wax extractor. It operated as well as it was represented to do, but still it did not answer the demand. Every day pieces of comb would turn up; they would be put in a barrel, until enough would accumulate to make it worth while to extract; by that time it would be full of moths. This was vexatious. I saw something in GLEANINGS that set me to work. In two hours I had a box completed that is worth more than any thing that I have seen or heard of.

I made a box 30 in. long, 14 in. wide, 14 in. deep, with a $\frac{1}{2}$ in.-square slat across each end, half the distance between bottom and top. On these I laid a $\frac{1}{2}$ in. board, 9 in. wide, $\frac{1}{2}$ in. thick; then a piece of tin 16×30 inches; I bent it up on two sides and one end. I filled this with comb, set it in the box on the middle board. All around the box, on the outside, projecting above the box $\frac{1}{2}$ in., I nail strips $\frac{3}{4}$ ×2 in.; then a lid 2 in. wider and longer than the box, hinged to the top strips, so as to shut over the box in time of rain. I put a piece of bright tin on the under side of the lid, so that when open to the right place the reflection will be on the glass. On the bottom of the box, under side, I nail a block 3×4 in., 5 in. long; bore a 2-inch hole through it, set a strong stake in the ground, perpendicularly to the summer sun; taper the tenant to one inch on top, set the box on the tenant so it will tip. On the top of the

box, in the rabbet made by the strips around the outside of the box, I laid 3 lights of 10×14 glass, and my machine is complete, and large enough for a 500-swarm apiary.

I should like to ask lots of questions, but you, may be, have answered them before. We read GLEANINGS, and now we must remain in ignorance; but still there are several things we should like to know, if you would answer; but we might not understand it, any more than we did Prof. Cook's big talk about honey-dew.

B. L. BRIER.

Jamestown, Tenn., Sept. 30, 1885.

Friend B., your sheet of tin is certainly an ingenious adjunct to a simple sheet of glass, and I should think it would answer nicely. Ask all the questions you wish, by all means, and we will try to make the answers plain. I thought Prof. Cook made the matter very plain about the honey-dew. Suppose you write directly to him in regard to what is not clear, and we will have your question and his reply given in GLEANINGS. Some of the veterans sometimes think we take an unnecessary amount of space in trying to make things plain to beginners.

FROM 33 TO 47, AND 100 LBS. OF HONEY.

I have been a close reader of GLEANINGS for several years, and as I read and ponder over the many trials, difficulties, and disappointments incident to apiculture, I oftentimes feel constrained to make mention of my ups and downs in bee-keeping. But, alas! when I attempt the task I find myself incapable of even getting together my own crude thoughts on apiculture, which I am sometimes tempted to ask space for in your journal. Soon I hope to not only see some of my views on Southern bee culture but a full description of our Wills Valley, in North Alabama, in GLEANINGS. I should say there is no other better location, naturally adapted to bee culture, in the whole State of Alabama, situated as we are between the two Lookout and Sand Mountains, in a rich fertile valley traversed by many water-courses. We have the greatest imaginable variety of honey-producing trees and flowers. From the early blooming of the maple to the late asters in the fall, we are scarcely without something from which the bee can secure nectar. Our bees now, Oct. 12, are busy on the white asters. Our yield for this season is, comb and extracted, each, 500 lbs., making 1000 lbs. in all. We had in the spring 33 colonies; increased to 47, which are now in fair condition for winter. We have Italians and hybrids. We winter on summer stands in Root Simplicities, with but little loss. This has been a very unfavorable year here for surplus.

C.—J. B. MARSH, 33, 47.

Collinsville, Ala.

CROSS BEES.

I have just commenced with bees, having purchased 29 full colonies. Before I could get the bees home they made a start with me, and for two weeks I had to go armed with a protector, gloves, and smoke; and for all the smoke, if I touched a hive they would boil out in front by hundreds, and fill my clothes full. I thought I was in for it, and that patent hives and all the Yankee inventions had failed to civilize this young heathen. There was no backing down. I had got the bees, and, worst of all, they often "got" me. I persevered gently with

these little friends, fed the weaker swarms, and soon they regarded me as a fast friend, and I often open the hives without gloves, protector, or smoker.

Rockport, O., Sept. 18, 1885. G. A. FARRAND.

ALSIKE CLOVER: ITS VALUE AS A HONEY-PLANT.

Prof. A. J. Cook, Lansing:—Will you not kindly say how many colonies and acres of alsike your brother had (see p. 697, Oct. 15)? also whether the alsike bloomed during white-clover bloom or later.

Terre Haute, Ind., Oct. 18, 1885. T. H. KLOER.

Prof. Cook replies:

I will say that my brother had about 80 colonies of bees, and nine acres of alsike clover. At the time mentioned, our white clover here at the college was in full bloom. My brother, however, cut his alsike early, to delay the time of blooming. While I much doubt if alsike clover is equal to the common red clover as a farm crop, I do think that for bees it is just admirable. It can be made to come late in the white-clover harvest, and just before the linden.

A. J. COOK.

Agricultural College, Mich., Oct. 22, 1885.

REPORTS ENCOURAGING.

FROM 71 TO 80, AND 3524 LBS. OF HONEY.

HERE is my report for the past season of 1885, in the apiary of A. M. Matthews, Pope Co., Ark. Out of 71 colonies in the middle of March, 18 were in Viallon Simplicity hives, 13 of which were queenless. The queens were lost in extracting the previous fall; 16 colonies were in box hives, with a Simplicity on top for surplus, and 37 in box hives, so I had to transfer 53 outdoors, late each evening. I increased by natural swarms to 80; and after doubling in the fall they counted 76. I took 3524 lbs. of honey—3136 extracted, and 388 lbs. comb. Our partnership has succeeded first rate, on account of both of us trying to do right, which the future will prove better.

Pittsburg, Texas, Oct. 19, 1885. C. J. DORFMAN.

I have had good success with my bees this year, and have sold a "right smart" of honey.

Jackson, Tenn., Aug. 24, 1885. G. B. CARTMELL.

I have taken, this season, from 16 hives, actual count, 748 lbs of honey, about one-third comb. I will report fully later.

Gonzales, Tex., Sept. 28, 1885. M. BROER.

FROM 15 TO 145, AND 130 LBS. PER COLONY.

Began with 75 colonies; increased to 145, and have extracted about 130 lbs. per colony so far, with the fall honey-flow yet to come. We have had a very wet season.

Hahnville, La., Sept. 8, 1885. C. M. HIGGINS.

FROM 28 TO 44, AND 2200 LBS. OF HONEY.

This is my first year in handling bees, although I have studied bee culture for three years. I started in June with 28 colonies. I have gathered 2200 lbs. of honey, and have now on hand 44 colonies, all in good wintering condition. I think I shall be able to rob at least ten of my colonies again. I have sold here about 100 lbs. of honey, and have on hand 1200 lbs. of extracted honey. Can you tell me a good market to sell?

Forsyth, Ga., Sept. 2, 1885.

R. P. BROOKS.

Honey Column tells all we know, friend B,

FROM 31 TO 50, AND 1000 LBS. OF HONEY.

Here is my report. As I am only an A B C scholar you must not expect too much of me. I bought 30 colonies last fall, and wintered in all kinds of boxes. They came out this spring with 16. I transferred all into the Triumph hive. I make my own hives now. I have increased to 50, and have taken 1000 lbs. of honey in one and two pound sections.

Dunkirk, O., Oct. 3, 1885.

W. A. MARTIN.

REPORT OF ONE SWARM OF BEES IN THE HANDS OF A BEGINNER.

My bees appear to be in excellent condition. From the colony I bought of you in May I had a swarm July 5th. This swarm made about 60 lbs. of honey in 30 days, and have been working in the second story for nearly a month. The original colony swarmed again about July 20th, a small swarm, but good workers. I also hived a swarm of black bees, which alighted near my place. I have given them away, because I did not know what the result would be to work black and Italian bees together. My experience has been very pleasant and interesting so far.

E. J. WHITEHEAD.

Southington, Conn., Sept. 3, 1885.

AN ENCOURAGING REPORT FROM TEXAS.

The basswood, our main dependence for nice honey, was so near a complete failure that I shall have but little honey to put on the market this season. My bees, however, are in excellent condition, and are working with a rush and will. I think they will gather an abundance of stores for fall and winter supplies. I have a fine lot of young queens from the last imported mother received of you, and they are turning out beautifully marked Italian bees. I am highly pleased with them.

Palestine, Tex., Sept. 8, 1885.

C. BRYANT.

FROM 9 TO 19, AND 600 LBS. OF HONEY.

As the time of year for reports has come again, I will send in mine. I opened the spring with 9 colonies, in moderate order; increased to 19 by natural swarms, except two I divided, and obtained 600 lbs. of choice comb honey, mostly in 1-lb. sections. My best yielded 100 lbs., and second best 90. I will give the record of one colony. About the tenth of May, No. 1 swarmed; and as I had old combs, the swarm had nothing to do but gather and clean up. In about three weeks I divided swarm No. 2, making No. 3; then in about two weeks No. 2 swarmed, and one week later No. 2 swarmed again, both of which have gathered plenty to winter on, and No. 2 gave 44 lbs. choice comb honey; and its mother, No. 1, 90 lbs. of surplus. Is not that good for a home-bred Italian queen, and not an acre of clover of any kind within range? All they had to work on was wild flowers, heart's-ease, and Spanish needles.

5—S. C. FREDERICK, 9—19.

Corl Vale, Kan., Oct. 4, 1885.

541 LBS. OF HONEY FROM ONE COLONY.

As I have just finished up taking honey, I will let you know, for the first time, how I am getting along with my bees. I have 30 hives of bees in good shape for winter, and have taken 1967 lbs. of honey from them, and they have plenty to winter on. My best hive has made me 541 lbs. of extracted honey. Of course, they did not all do that, or I should have to dig a pool to put it in. They have averaged 65 lbs., counting the capital hive. Now for the Clark smokers. Some are bothered with them by choking up,

and I was too; but gumming up three or four taught me how to manage it. Burn sound chips instead of rotten stuff or rags; and when it takes the quinsy, blow it until it gets very hot, then point it to the ground and blow as hard as you can. A few puffs will start its lungs to action, and the trouble is over.

A. L. LIGHT.

Pastoria, Ark., Sept. 6, 1885.

Well done, friend L. The above report not only speaks well for you, but well for your State of Arkansas. Was the large amount of honey made entirely by one colony, or from the colony and its increase?

FROM 64 TO 100, 7200 LBS. OF HONEY, AND 75 LBS. OF BEESWAX.

Commenced the swarming season with 64 colonies. Increased to 100. Comb honey, 5500 lbs.; extracted, 1700 lbs. Total, 7200. Beeswax, 75 lbs.

Silverton, Oregon, Oct. 3, 1885. E. S. BROOKS.

NOTES AND QUERIES.

A GREAT FALLING OFF IN THE PRODUCTION OF HONEY IN CALIFORNIA.

VENTURA County will not ship over one hundred tons of honey this season, as but few apiaries have more than enough for home consumption; whereas last year the estimated shipments were two thousand tons. Bees are cheap; this is a good time for eastern bee-men with poor health to start in the bee-business in one of the healthiest counties in the State.

Santa Paula, California. L. M. HADRISEN.

BEES AND RASPBERRIES.

Bees do work on black cap raspberries, but not so much as on the red.

MAHALA B. CHADDOCK.

Vermont, Ill., Aug., 1885.

A GOOD REPORT FROM ALLEY'S TRAPS.

I used $\frac{1}{2}$ doz. of Alley's queen-traps last year; no more swarms leave for the woods when I am away from home.

W. E. FLOWER.

Ashbourne, Pa.

ANOTHER SWARM GOES OFF WITHOUT ALIGHTING.

We had two swarms this year, but the first flew away without alighting.

A GOOD REPORT OF THE POULTRY NETTING.

That wire for the chicken yard is just the thing. It gives them a large space, and we have had only three or four fly over, and after we clipped them no more have tried it.

GEO. F. CLEVELAND.

Collamer, O., Aug. 26, 1885.

WILL EARLY-AMBER MOLASSES DO TO FEED?

I see by your catalogue that Early-amber sugar will do to feed bees. What do you think about Early-amber molasses? Would it do to feed for brood-rearing? Would not the sugar reduced to syrup be the same as molasses? A neighbor of ours saved a swarm last spring that was destitute, by pouring about a quart of Early-amber molasses in among the bees and combs.

MRS. H. BABSON.

Lower Salem, O., Oct. 3, 1885.

[Mrs. B., the Early-amber molasses, or, in fact, any other kind that the bees will use, will answer for spring feeding; but so far as my experience goes, all these low-priced syrups are not sufficiently free from foreign matter to be suitable for winter stores. Better save your Early-amber syrup till spring, and use only pure white sugar for winter stores.]

ANOTHER NUCLEUS THAT PERSISTS IN KILLING QUEENS.

It has not been a good summer so far. I have lots of trouble with a nucleus colony. They are determined to have no queen. They have killed four Italian queens, and two of them after the queens had commenced laying. The queens cost me \$1.00 each.

J. W. PORTER.

Ponca, Neb., July 21, 1885.

[The only remedy I know for such cases is to put a good lot of brood-combs into the hive, so that the young hatching bees may outnumber the stubborn and ill-tempered old bees.]

HOW TO PLACE FEED OVER THE CLUSTER.

I wish you would tell me how I can place the feed that you recommend on pages 13 and 14 of your catalogue—the feed which is made of powdered sugar and good honey, and is placed over the cluster—without letting the bees fly out while I am doing it.

N. LUMAN GERRISH.

Nottingham Center, N. H., Oct. 8, 1885.

[Friend G., it is a pretty hard matter to feed bees, any way you can fix it, without causing them to fly out. If the weather is warm, so they can all get back again, it does no harm to let them fly out, that I know of. During cold weather, if you remove the cushion quickly and turn back the burlap, you can usually get a ball of the candy right over the cluster, and get the hive closed up before the queen takes wing.]

HONEY-ANTS.

I got some honey-ants this morning. They build a nest in the ground, and have a room. There are three different kinds—the queens, workers, and one other kind. Their bodies are full of honey. When one of the workers wants some honey it caresses the feelers of one of these, and she feeds him in the same manner as a bee. Don't you think you could get Prof. Cook to tell us some of their habits, and let us know in GLEANINGS?

W. B. KENDALL.

Uvalde, Texas.

[Friend K., Prof. Cook has already told us about these ants. I think you will find some mention of them in his Manual, and I think he wrote an article in some of our journals, though I can not say just now where you will find it. Will friend Cook please tell us where such a paper is to be found, if he did write one?]

HOW FAR DO BEES FLY, AND WORK PROFITABLY?

How far can bees go for honey, and make it profitable? Can they make it profitable with pasturage two miles off?

C. W. HARDY.

Burnet, Burnet Co., Texas.

[Friend H., this matter has been discussed at considerable length in our back volumes. Bees ordinarily do not go more than two or three miles for stores, if I am correct; but under some circumstances they have been known to fly six or seven miles, and accumulate honey, even then. These great flights are usually across a body of water, or over a prairie, under circumstances where neither timber nor hills inconvenience them.]

THE STANLEY AUTOMATIC EXTRACTOR.

We see in Aug. 1st No. a call for reports of Stanley's automatic extractor. We have used one this season, and must say it is the best now on the market. We have extracted over 2000 lbs., and in one-half the time it takes with other makes. We would no more think of using an extractor not reversing the combs automatically, than of using a cradle in the place of a self-binding reaper.

Geddes, N. Y.

F. A. & H. O. SALISBURY.

We had a very severe drought in spring and summer, after a dry and cold winter. The white clover was an entire failure. I saw only one swarm of

bees from 43 old stands, so our honey crop is a failure. I am not able to buy any new hives this season. I endeavor to make them pay their own expenses.

L. C. MAJOR.

Brandy Station, Va., Oct. 10, 1885.

GLEANINGS IN BEE CULTURE.

MEDINA, NOV. 1, 1885.

For God sendeth his rain on the just and on the unjust
MAT. 5: 45

THE KANSAS BEE-KEEPER.

In answer to several inquiries, we are obliged to state that the above paper is no longer published. As to whether they have made arrangements with their subscribers for the unexpired time, we are unable to say; but from what we know of the proprietors, we should suppose that, of course, they have. There is nothing wrong in withdrawing from a business speculation, whenever it becomes unprofitable, providing you make good all your unfinished contracts with your fellow-men; and I believe the bee-papers that have suspended during the years that are past have always made it a rule to do this.

WIRE CLOTH MADE OF STEEL WIRE GALVANIZED,
FOR CLOSING THE OUTLETS AND INLETS
OF CARP-PONDS.

In consequence of the many inquiries in regard to this article, we have got the manufacturers to make us a special lot to order, for the above purpose. I have before explained to you the reason why we are enabled to get prices very much less than the ordinary price. The material (steel wire) makes it tremendously strong; and being thoroughly galvanized by dipping it in melted zinc after it is made, it is absolutely rust-proof. There are four meshes to the inch (8 mesh same price), and the price is 10 cts. per single square foot; 85 cts. for 10 square feet, or \$7.50 for 100 square feet. If wanted by mail, add 10 cts. per square foot extra for postage. We have only one width in stock; viz., 36 inches.

HUTCHINSON'S SHIPPING-CASE, FOR 14 SECTIONS,
FOR ONLY 6 CTS., IN THE FLAT.

W. Z. HUTCHINSON sends us a sample of his tent-case for shipping comb honey. You will notice by his advertisement that they are only 6 cts. each, in the flat. We presume this latter price does not include glass, since he does not say so. But in any case the price is very low for so good a case. We like it so well that, if friend H. has no objections, we will furnish them at his prices. The case is light and strong; and the narrow slip of glass, that gives us a glimpse of the nice comb honey, is so well protected that there is very little liability of breakage. Very likely a good many small dealers will take one of these cases where they won't care to invest to the amount of a case holding 24 sections. Although the

case is very light, it is strong enough to stand shipping, probably, without injury. It weighs only 2½ lbs., and can therefore be sent by mail to those living at remote distances, at an additional expense of 40 cents for postage.

INDUCEMENTS TO SUBSCRIBE EARLY.

ALL subscriptions received between now and the first of January, for the year 1886, will include the remainder of 1885 without charge. That is, any new subscriber who sends in his subscription before the year is out will receive the journal free for the remainder of this year, after his subscription is received. Do you ask why we are partial to new friends, to the exclusion of old ones? Well, we do not mean to be; therefore we will give every old subscriber, who remits between now and the 15th of this month, any article he may choose from our 10-cent counter, providing he specifies what article he wants, and sends the correct amount of postage, if it is to be sent by mail. Very likely you may not consider ten cents very much of an inducement; but there are little folks in almost every bee-keeper's home who will be glad enough to get it.

THE PRESENT NUMBER OF SUBSCRIBERS.

We are glad to be able to say that we have, at this date, 6618 subscribers. This is considerably higher than we have reached at any time before this year. Thank you; and while I think of it, I might mention that in our next issue we shall commence giving eight additional pages in the middle of each month. These extra pages will be occupied by an article that will probably go through all of 1886. The title of this serial will be, "What to Do, and How to Be Happy in Doing It." We expect it to be copiously illustrated with many fine engravings. The papers are especially intended for those who are thinking about something to do during the long winter months and evenings just now before us. Our older readers will probably rightly surmise that it will pertain specially to "Home Interests" and rural industries.

ANOTHER DRONE-TRAP.

MR. JOHN A. BACHELDER, of Keene, N. H., sent us a drone-trap last May that is not only a wonderful piece of mechanical ingenuity and workmanship, but it is a good deal ahead of any thing we have yet seen. The trap was given to our apiarist to test; but by the time he reported on it the letter accompanying it was mislaid. We humbly beg friend Bachelder's pardon, and will try to be more careful next time. The price is \$1.00 each, by mail. Friend B. says the trap was completed in July, 1883, and that a notice in regard to it was sent at the time. It works beautifully. We may have an illustration of it before another season opens. Friend B. says it will cage a queen, although we have never tested it in this respect. The bees, even when laden, enter almost as well as through the usual entrances, and the greater part of them come out the same way. The pollen is not scraped off.

A DROWNING BEE.

WE take the following from the *British Bee Journal*. It is worthy of the distinguished minister who wrote it:

Mr. Spurgeon writes as follows in the September number of the *Sword and Trowel*:—A poor bee had fallen into the pond, and was struggling as well as her failing strength would allow. We seized a pole, and placed the end of it just under her. She took firm hold, and we lifted the pole and the bee. A

little while was spent in drying herself and plumping her wings, and then our worker made a straight line for the hive, and doubtless was soon at her daily task rewarding us with honey. May not many a human worker be found in a sinking condition? A little sensible help might save him. Who will give it? He who does so shall receive the blessing of him that is ready to perish. Poor hearts are often in deep despondency, sinking for lack of a sympathetic word. Do not withhold it. Rescue the perishing. Be on the watch for despairing minds; if no other good comes of it, you will at least be more grateful for your own cheerfulness. But good will come of it in unexpected instances, and it will be heaven's music in your ears to hear sighs turned to songs.

KIND WORDS FROM OUR CUSTOMERS.

A KIND WORD FOR VOL. IV. OF GLEANINGS.

Please accept my thanks for being so prompt in attending to my order, and excuse my negligence in not before acknowledging the receipt of the same. Vol. IV. of GLEANINGS is more than I ever expected for 25 cts. G. SCOTFIELD.

Ridgeway, N. Y., Sept. 27, 1885.

AN ENCOURAGING WORD.

We received the last package of goods all right, and in better order than any preceding lot. I think they were packed more securely. Mail matter receives some very rough handling in coming all this distance, and needs very good packing. We were more than pleased with the goods, and wonder how you can sell so cheap. A. W. HINDE.

Anaheim, Cal., Sept. 4, 1885.

Inclosed find \$1.00 to pay for GLEANINGS. I like your talks on the practical, every-day topics that should interest us all very much; and although I do not keep bees, I am glad to read GLEANINGS for its high moral tone. May God in his providence give its editor long years of prosperity, is my prayer. A. D. HOVEY.

Chardon, O., Aug. 31, 1885.

A PLEASSED CUSTOMER.

The saw and mandrel I ordered of you came all right—just what you represented it to be. Thanks. I find I like the hum of it better since I use a 4-horse engine to drive it. I shall likely want more of your wood-working tools before long. I don't mean to flatter, but you are the best man to deal with I have found yet. N. F. HILLS.

Gilman, Ill., Sept. 8, 1885.

TWO NUCLEI PURCHASED JUNE 8 MAKE 7 GOOD COLONIES BY SEPT. 5.

As I was writing for some books this morning, I write you a few lines to let you know how the bees got along that I had of you. You shipped them on the 8th of June, and I got them on the 12th. They were at the express office on the eleventh, but I did not get your card till the 12th at noon. I had to go for them in the afternoon a distance of eight miles; got them safely home, and in the hives that night. Three of them were for Mr. McDonald, and two of them for myself. My own have done very well considering the season, which has been so cold and wet. They have increased to seven good strong colonies. Your manner of doing business suits me well. I intend to try your plan of wintering on sugar this winter. J. S. MOORHOUSE.

Dealtown, Canada, Sept. 5, 1885.

A GOOD REPORT FROM THE NUCLEI WE SEND OUT.

The goods arrived all right and in good season. I was very much pleased with them, and I can not but wonder at the promptness and good condition in which they were received, taking into consideration the distance from which they came, which speaks well for your careful mode of packing, and endeavor to please. Nothing is left for me to do but to express my heartiest thanks for all you have done for me so far, and my confidence in all future dealings. Last Monday my brother and I opened three hives, and I had invited an old friend of my father's, who has been a bee-keeper for 30 years, to come and look at them, and he pronounced

them beautiful Italians, and that we had been wise to buy them, for it was really a bargain to get such bees in good 8 hives, and such populous colonies, at \$7.00 a hive. I tell you it made me feel well to have such an old veteran at bee culture talk so encouragingly, for he is apt to be very sarcastic, and depreciate things, unless they are really good. We saw the queens of all three hives, and you can imagine how eager we were to see a queen, having never seen a live one in our hives, and how pleased and astonished we were on seeing her, at her great size and beautiful yellow color. We noticed that there was not an over-abundance of honey in the brood-combs, but we suppose that considerable was consumed while transporting and in opening the hives. We think they will soon have enough for winter, judging from the way they are working.

Newark, N. J., Sept. 10, 1885. C. H. THEBERATH.

A GOOD REPORT FROM OUR 24-LB. 83.75 SCALES.

The scales ordered from your house, a short time ago, came to me in good order. I am pleased with them. They are better than I expected. The freight charges were \$2.50, making the cost \$6.25, laid down here. The same scales (but Fairbanks') cost \$12.00 to \$14.00 here. A word for the regular-sized section, $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{1}{2}$. I have taken out 5300 lbs. of comb honey this season. Out of the lot there was not to exceed 300 bulged, so they would not crate. There were more imperfectly filled sections, but not bulged. They are good enough for me, and I expect to let well enough alone. No separators. E. S. BROOKS.

Silverton, Oregon.

HONEY IN ENGLAND: HOW WE SUCCEEDED IN SHIPPING THE LAST LOT.

The last lot of honey that you sent was first class—nothing could be better—and the packing was superb—not a drop of honey lost. There has, however, been an immense increase in the production of honey in England during the last two years, and a vast improvement in the methods used; the result is, that there is now a very large supply of first-class clover honey raised in England. It can be got wholesale at 5 ds. and 6 ds. per lb. here, just half what it was two years ago. This is cheaper than first-class American honey, with cost of transport added. The stores with which I am connected find that at present they can get first-class honey cheaper from English producers; and while this continues, we shall not require honey from America. It is said that there is a vast importation of first-class California honey. I can not see how it can pay a man, who can get 5 cts. or 6 cts. a lb. for honey in America, to transport it to England where it will fetch about the same price. But I have since been told that high-class California honey is sold in Liverpool and London at 35 s. per cwt., or 37 ds. per lb., or 7½ cents per lb. I got a specimen, but it was not first-class clover honey. But although not first-class, I am surprised that it should pay any one to import and sell it at that price.

Oxford, England, Sept. 26, 1885. A. C. HAMILTON.

[Perhaps we ought to explain, that the above shipment consisted of 3000 lbs. It was all put up in iron-jacket cans, and two of them were crated together, so as to make a good strong package. Good sound corks were selected, of such size that they would go in only when mashed. They were then fastened with a strip of tin, soldered over the top, and we succeeded, as you notice in the above.]

THE CANADIAN BEE JOURNAL.

WEEKLY, \$1.00 PER YEAR.

D. A. Jones & Co., Publishers, Beeton, Ont., Can.

The only bee journal printed in Canada, and containing much valuable and interesting matter each week from the pens of leading Canadian and United States bee-keepers. Sample copy sent free on receipt of address. Printed on nice toned paper, and in a nice shape for binding, making in one year a volume of 832 pages. 97th

Farm for Sale. 60 ACRES—75 improved. Two barns—good house and cellar. Living water, abundance of fruit of all kinds. One-half mile to R. R. Two miles to station. For particulars address N. L. HIGBIE, M. D., 214 E. 10th St., Elsie, Clinton Co., Mich.

CONVENTION NOTICES.

The Central Michigan Bee-Keepers' Association will meet in the Pioneers' Room, in the State Capitol, at Lansing, Mich., at 9 A. M., Nov. 12, 1885. Every one who has bees, or is interested in bee culture, is invited to attend. E. N. WOOD, Sec'y.

The Southeastern Michigan Bee-Keepers' Association will not hold any meeting here this fall, as the North American, the Michigan State, and the North-Western, all meet together within the territory covered by this Association (at Detroit), and it comes so close to the time of ours that we have concluded to attend there. A. M. GANDER, Sec'y.

Adrian, Mich., Oct. 20, 1885.

NOTICE TO BEE-KEEPERS.

I propose making an effort with the Canadian railways for reduced rates to Detroit N. A. B. A. (Dec. 8, 9, and 10). Will all bee-keepers who can or will use said railways to attend said convention, kindly drop me a card, stating the road they prefer to use, or the roads they could use in case arrangements can be effected with one line only? When we approach railroad men we must have some data to talk from.

S. T. PETTIT, Vice-Pres't
for Ont. Branch of N. A. B. A.

Belmont, Ont., Can., Oct. 15, 1885.

NORTH AMERICAN BEE-KEEPERS' ASSOCIATION:
HOW TO FIND THE HALL; HOTEL RATES, ETC.

Free and complete arrangements have been made for the next meeting of the North American Bee-Keepers' Association, to be held at Detroit, Dec. 8-10. Hotel rates were obtained at \$1.25 per day. (Their regular rates were \$2.00.) We secured the use of what is known as the "Red Men's Wigwam," a nice hall, directly opposite the hotel. It is well furnished and carpeted. It is located at 63 Michigan Ave., about 20 rods from the City Hall, so you will see that it is very centrally located. The Antisdel House, where the above rates were secured, is a splendid place to stop at. Mr. Antisdel has the reputation of keeping the best temperance hotel in Michigan, and, taking all in all, we were very fortunate in securing so good a place, and in getting a hall so near. The committee are at work on reduced rates on railroads, and, so far, have succeeded in securing rates on all roads in Michigan and on all tickets sold as far east as Buffalo and west to Chicago. We are in hopes to get rates from New York, as far west as possible. The matter is in correspondence, and you will receive due and timely notice. Now that all arrangements have been made for a successful meeting, let every one come and make it a success. H. D. CUTTING.

Clinton, Mich., Oct. 19, 1885.

Plymouth Rocks. Fine, pure-bred Cockerles of this popular breed at \$1.00 each, if taken before Nov. 15. Satisfaction guaranteed. Ref. *Ed. Gleanings*. Address
20-21d YODER & METZLER, E. Lewistown, Mahoning Co., O.

DADANT'S FOUNDATION FACTORY, WHOLESALE AND RETAIL. See advertisement in another column.

FOR SALE,

A SECOND-HAND TWO-HORSE-POWER
EUREKA ENGINE AND BOILER.

The above engine has been in use about five years; but Mr. A. F. Stauffer, of Sterling, Ill., of whom we purchased it, writes in regard to it as follows:

I guarantee the engine to be in good working shape, as good as it ever was. I had boiler examined last spring by a steam-fitter, and he pronounced it as good as new. I always used soft water. I am furnishing my shop with new machinery and am anxious to sell or exchange it. I have to get more machinery, and my two-horse power is too light.

Sterling, Ill. A. F. STAUFFER.

We will sell the above engine, to be taken at Sterling, Ill., for an even \$100, and we will put our guarantee on top of that of friend S. We obtained it of him in exchange for some new machinery, he, of course, putting in a larger engine and boiler.

A. I. ROOT, Medina, Ohio.

LET YOUR LIGHT SHINE.

I feel, when I read GLEANINGS, and find so much kindness expressed all through its pages, that I can only exclaim, "God bless brother Root!" Let your light so shine, that others may see; and seeing, may learn to walk in the ways the Master has pointed out.

F. L. SMITH.

Chittenango, N. Y., Sept. 1, 1885.

Here it is again—be careful! I did not expect you to serve me so. I thought you would send the two Carniolan queens in four or five days, but here they are in 48 hours. The matter needs no explanation. Fast trains and prompt attention put us near each other.

J. F. MICHAEL.
German, Darke Co., O., Oct. 22, 1885.

The untested queen purchased of you a few weeks since came to hand all right, and her worker progeny are beautiful three-banded Italians. Many thanks for the despatch with which the order was filled, as I needed her badly, having at that time only one colony and suitable brood for queen-rearing.

NASH.

Monroe, Ia., Sept. 21, 1885.

The Waterbury watch arrived by last mail in good order, and has been running two days, keeping good time—giving complete satisfaction. Please accept thanks. I hope to be able to send you yet other names of subscribers to your excellent paper, as there are other bee-keepers in this vicinity who should read GLEANINGS.

J. L. HOSKINS.

Newburg, Oregon, Oct. 26, 1885.

WHAT HE THINKS OF OUR SECTIONS.

The goods came yesterday; thanks for promptness. The sections are lovely. Why, Mr. R., I didn't know there were such sections as these. You never sent me any thing like them before. If I had only had them for my white honey!

Templeton, Pa.

E. H. MCCLYMOND.

HOW THE NEW SHOWCASE IS APPRECIATED.

The show-case has just arrived safely. It is very neat indeed. Your lawn-mower is also pronounced a perfect success, by all who try it. I fear I may have been very dull in recognizing what a public benefactor you are, in providing for us all these conveniences.

MRS. H. HILLS.

Sheboygan Falls, Wis., Sept. 3, 1885.

PRaise WHERE IT IS DUE.

With sincere gratitude I acknowledge the receipt of your statement, and—to balance account, I believe that, "such as you measure to others shall be measured to you again," etc. I have dealt mostly with you for supplies, and have been satisfied. You dealt fairly with me; of course, distance and freight sometimes interfere, then we have to struggle economy. Flattery is not my intention, only praise where it is due.

WILLIAM BROWNING.

Garden Grove, Iowa, Aug. 29, 1885.

GLEANINGS—HOW IT SUITS.

That GLEANINGS does dish up to us a "mixture" is one of the strong reasons why I can't do without it. Bro. Root, believe me, I would eat but one meal of victuals per day until I had saved enough to pay for GLEANINGS before I would do without it. May God bless you for your words. May you gain an abundant entrance for being faithful over a few things, is the prayer of your brother in Christ. Go on in the good work. I, with thousands of others, am praying for you.

CHARLES I. SEELEY.

Greenville, Mich.

KIND WORDS, AND NO MISTAKE.

I have received and read the GLEANINGS sent me, and, like Mr. Higgins, of Louisiana, it brings me to my feet to say I admire your course in "mixing up" a little good that will make people better, as well as good bee-keepers. It causes me to send for GLEANINGS, and I hope thousands of others to do likewise. My bees are doing well. The only enemy to bees in this part of Texas is the moth. I never saw in print any thing about our best source for fall honey—the live-oak balls. I think it accounts for bees wintering so well in Texas. I have 106 hives, mostly Simplicity.

M. SIMPSON.

Gatesville, Coryell Co., Texas, Oct. 26, 1885.

KIND WORDS FROM OUR CUSTOMERS.

It is a pleasure to deal with one who is as prompt and reliable as I have found you.
Southington, Conn. E. J. WHITEHEAD.

The extractor arrived in good condition this morning. We have tried it, and are well pleased with it. Many thanks for your promptness.
Pickering, Md., Sept. 16, 1885. G. B. MCARTHUR.

REPORT FROM THE NEW JOHNSTON FORCE-PUMP.

The pumps work like a charm. They are the best cheap pumps that were ever introduced here.
Quincy, Mich., Oct. 30, 1885. FRANK D. CALVER.

I have raised some of the finest queens I ever saw, from that select queen I got of you. Their bees are the most gentle and finely marked I ever saw. The old queen is doing well yet.
Cassville, Mo., July 24, 1885. A. N. TWILLIGEAR.

DOES IT PAY TO ADVERTISE IN GLEANINGS?

Judging from the correspondence that I have already had, I think you had better not insert my ad't again. Many thanks for your extensive advertising medium.
J. W. HART.

Eureka Springs, Ark., Sept. 22, 1885.

OUR EXTRACTORS AT FAIRS.

I have been very busy, and have been at several fairs. I got a silver medal at the New England and first prize at the State Fair on your extractors.

W. H. NORTON.

North Madison, Me., Sept. 28, 1885.

The goods ordered of you have arrived and been unpacked. They all came in splendid order, and give general satisfaction. We think that the pumps will be all right, although they are of a different pattern from what we have been selling.

Portland, Or., Sept. 26, 1885.

MILLER BROS.

OUR HONEY-TUMBLERS AND LABELS.

My labels have been received, also the 100 honey-tumblers. I am especially pleased with your mode of packing. The freight charges were very reasonable, only 75 cents for the tumblers.

WATSON ALLEN.

Bernardsville, N. J., Sept. 22, 1885.

OUR COMB FOUNDATION.

I received the one pound of foundation in due time. It being my first to handle, I was surprised to see the neatness in the work, also the manner in which it was packed. It was all right—not marred in the least.

S. TURNER.

Erie, Kansas, Sept. 17, 1885.

The queens shipped to me Aug. 25th arrived yesterday, and were introduced; but I left in the tin slides until this morning. After finding the bees friendly I withdrew them, and feel sure all will end well. Thank you for promptness and kindness. These keep your customers. I try to keep a small sum with you against which to draw orders; but sometimes I can not do it; but my requests are always honored by you, for which I thank you.

MRS. W. W. WILSON.

San Bernardino, Cal., Sept. 3, 1885.

DOES IT PAY TO ADVERTISE IN GLEANINGS?

Last winter I got a carload of hives. In the lot I got 100 of the A. I. Root Simplicity hives. I sent an advertisement to GLEANINGS, and to two other papers, but I do not know that I got a single return from any but GLEANINGS. Parties sent for price lists as far south as Texas, west as far as Nebraska, east as far as Pennsylvania, and north as far as Michigan. Not a single one wanted the 17% frame—all wanted the Simplicity hive, or that frame at least, so you see my 100 hives were soon exchanged for bees, in other sorts of hives. J. R. LINDLEY.
Georgetown, Vermilion Co., Ill., Oct. 17, 1885.

HOW OUR SUPPLIES GIVE SATISFACTION.

The goods which you shipped to me Aug. 12th came to hand in good condition, and very promptly too. They were at the station within a week after I mailed my order, which is quick work, as they came by freight. I took the extractor, hive, comb-basket, swarming-box, and honey-knife to the Crawford Agricultural Society at Conneautville. All took first premium but the honey-knife, which took second. There were two other hives to compete with yours. The extractor attracted much attention. Very few ever saw an extractor in this part of the country. GEO. SPITLER.
Mosiertown, Pa.

HONEY COLUMN.

CITY MARKETS.

NEW YORK.—*Honey*.—The market for comb honey is quite active, and demand good, although prices are gradually shading, owing to the fact of many producers selling their entire crop in this city at very low prices, thereby enabling purchasers to sell below the market. We know of large crops having been sold here at 9@10c. for fancy goods. In consequence of no honey coming from the west, we can see no reason why good prices should not be obtained, except above stated. Present quotations are as follows:

Fancy white comb honey, 1-lb. sections	- -	14@15c
" " " " " 2-lb. "	- -	11½@12½c
" buckwheat " 1-lb. "	- -	11@12c
" " " " " 2-lb. "	- -	9@10c

Off grades, 1@2c per pound less.

Oct. 28, 1885. McCauley & HILDRETH BROS.,
34 Hudson Street, cor. Duane St., New York.

CINCINNATI.—*Honey*.—There is a very slow demand from manufacturers for extracted honey, with a large supply on the market, while the demand is very good for clover honey in square glass jars. Prices for all qualities are low, and range from 4@8c per lb. on arrival. Supply and demand are fair for choice comb honey in small sections—which brings 12@15c. per lb. on arrival.

Beeswax.—Good yellow is in good demand, and arrivals are fair. It brings 20@22c per lb. on arrival.

CHAS. F. MUTH,
S. E. Cor. Freeman and Central Avenues,
Nov. 10, 1885. Cincinnati, O.

CLEVELAND.—*Honey*.—There is quite a demand now for choice white 1-lb. sections at 14@15 cts., and all lots of new closed out. Of old, we still have a good supply, which sells very slowly at 10@13. Extracted seems to be in some request, and choice white would sell at 6@8c. *Beeswax*, very scarce at 22@25.

A. C. KENDEL,
Nov. 10, 1885. 115 Ontario St., Cleveland, O.

ST. LOUIS.—*Honey*.—Market rules as follows: Extracted Southern, in bbls., 4@5c. Half-bbls., 5@5½c. Northern, in cans, 8¼@10c. Retail—comb honey, white clover, 17@20c. in 1-lb. sections. Not much demand for dark. *Beeswax*, steady at 24@25c.

W. T. ANDERSON & CO.,
Nov. 10, 1885. 104 N. Third St., St. Louis, Mo.

BOSTON.—*Honey*.—We think we notice a little better feeling in the honey trade; but prices remain the same. White clover, 1-lb. comb, 14@16; 2 lbs., 12@14. Extracted, 6@8. BLAKE & RIPLEY,
Nov. 11, 1885. 57 Chatham St., Boston, Mass.

CHICAGO.—*Honey*.—We are having a very good trade in honey at present, which will likely continue until about the 10th of December. White comb honey in good order is firmly held at 15@16c; extracted is bringing 6@8c, according to body, flavor, and package. *Beeswax*, yellow, 25@26c.

R. A. BURNETT,
Nov. 10, 1885. 161 So. Water St., Chicago, Ill.

MILWAUKEE.—*Honey*.—This market continues very nearly in the same condition on honey as when we last advised you. Demand fair, and stock not very large—room for more choice comb in 1-lb. sections. White, 15@16. Extracted, in bbls. and kegs, 7@8c.

A. V. BISHOP,
Nov. 11, 1885. 142 W. Water St., Milwaukee, Wis.

WANTED.—1000 or 2000 lbs. of nice white comb honey in 1-lb. boxes; must be cheap—Ohio honey preferred. Address, stating price,

B. T. BLEASDALE, 596 Woodland Ave., Cleveland, O.

WANTED.—200 lbs. of fall honey. Must be well ripened. Who will furnish the cheapest, in vessels holding not more than 100 lbs.? Send sample, and state price. W. H. LAWS, Ft. Smith, Ark.

Wanted. Situation with some bee-keeper. Have had three years' experience.
22tfdb W. C. WRIGHT, Reagan, Falls Co., Tex.

DADANT'S FOUNDATION FACTORY, WHOLESALE AND RETAIL. See advertisement in another column.

EXCHANGE DEPARTMENT.

Notices will be inserted under this head at one-half our usual rates. All ads intended for this department must not exceed 5 lines, and you must say you want your ad in this department, or we will not be responsible for any error.

WANTED.—In exchange for new varieties of strawberries and raspberries, Plymouth Rocks, Light Brahmas, Pekin Ducks, new varieties of potatoes, and small-fruit plants, cherry and quince trees. P. SUTTON, Exeter, Luz. Co., Pa. 16-23db

WANTED.—To exchange one-half bushel of extra fine white clover seed for alsike clover seed. 19tfdb M. A. GILL, Viola, Rich'd Co., Wis.

WANTED.—To exchange money or honey for a Normandy male hog, 8 to 12 months old, or improved Chester White. Must be a fine hog. Address J. B. MURRAY, Ada, Hardin Co., O. 22tfdb

WANTED.—To exchange bees and queens for a good printing-press, with furniture and type. Give description and price. Address Box 2, Benton, Bossier Parish, La. 22tfdb

WANTED.—In exchange for Italian bees, 40 acres of good hammock land on Manatee River, Florida, suitable for all tropical fruits, sugarcane, vegetables, etc.; good bee country, no apiary within miles. Address F. SCHINDEL,
22tfdb Fort Ogden, Man. Co., Fla.

DADANT'S FOUNDATION FACTORY, WHOLESALE AND RETAIL. See advertisement in another column. 3btfdb

TILLINGHAST'S FAMOUS PUGET-SOUND CABBAGE SEEDS are being introduced in every section of the country in a novel way. Instead of depending upon seedsmen to catalogue them, Mr. Tillinghast is appointing some person (usually a cabbage-grower, who knows what good cabbage seeds are), in each town throughout the Union, to act as agent and sell to his neighbors. Parties interested in selling or planting cabbage seeds may learn something to their advantage by addressing Isaac F. Tillinghast, La Plume, Pa. 22d

DADANT'S FOUNDATION FACTORY, Wholesale and retail. See advertisement in another column. 3btfdb

Vol. XIII.

NOV. 15, 1885.

No. 22.

TERMS: \$1.00 PER ANNUM, IN ADVANCE; 2 Copies for \$1.90; 3 for \$2.75; 5 for \$4.00, 10 or more, 75 cts. each. Single Number, 10 cts. Additions to clubs may be made at club rates. Above are all to be sent to ONE POSTOFFICE.

Established in 1873.

PUBLISHED SEMI-MONTHLY BY

A. I. ROOT, MEDINA, OHIO.

Clubs to different postoffices, NOT LESS than 50 cts. each. Sent postpaid, in the U. S. and Canada. To all other countries of the Universal Postal Union, 15c per year extra. To all countries NOT of the U. P. U., 42c per year extra.

OUR OWN APIARY.

SIX HIVES KNOCKED OVER BY A RUNAWAY HORSE:
LATEST SPECIAL FROM THE SCENE OF ACTION.

NOV. 6.—This afternoon, about 1:30 P. M., the new horse, "Meggy" (the one that fills Nancy's place), while on the outskirts of the apiary took flight and started to run. Wheeling abruptly about, she upset the wagon, precipitating Messrs. Weed and Somers violently to the ground. Neither, however, were hurt. Kicking furiously, she dragged the wagon half through one of the apiaries, knocking over grapevines and hives with a vengeance that was calculated to clear the track of obstructions of any kind whatever. The wagon becoming wedged among the hives and grapevine trellises, she commenced kicking again, until she had freed herself; but the thills still clung to her as she dashed on. At this juncture I leisurely made my way to the hives, for I am notoriously slow sometimes. The horse was rapidly escaping up the road, while her pursuer, having picked himself up, was laboriously plodding after. Meantime the apiarist, who evidently did not relish this situation, was doing his best to set things right side up, screwing his face, as he did so, in a manner that betokened pain, while with quick jerks he rubbed from his hands the stings which

THE INFURIATED BEES

were inflicting. I soon was there with veil and smoker; and not long after, the hives were at least right side up. One was turned completely upside down, and the other five were either thrown upon the sides or pretty badly jammed, to say nothing of broken frames. The colonies had already been

packed for winter. After the mishap there was a mixture of combs, chaff, and bees—the latter, of course, boiling out like mad hornets.

Nov. 10.—The hives are all put to rights now; the wagon is repaired, and Meggy, apparently uninjured, draws the market wagon as before.

Moral.—Be careful with high-spirited horses near the apiary.

LOOK OUT FOR SMALL BOYS.

Once or twice we have been annoyed by having the slates displaced, upon which the record of the hives was kept. A little investigation showed that a

SMALL BOY

bearing the name of "Huber" had been there. Even at this early age he manifests quite a fondness for busying himself among the hives. Whenever he is missing, and the accustomed racket has become lulled, we invariably suspect mischief; so in this case. He thought it rare fun to pull those slates off the hives, and then pile them up in little heaps, or scatter them in every direction. Taking into consideration the number of imported queens in the apiary, this might have been pretty expensive business, had, not, fortunately, the apiarist already marked these hives independently of the slates. Otherwise we should have been in a "peck of trouble."

PUTTING THE BEES INTO WINTER QUARTERS.

In my remarks here I shall particularize how our bees are put into winter quarters, for the benefit of those who may wish to know just how *we* do it. I therefore hope the veterans will excuse me if I seem to indulge in a little repetition.

As stated in a previous number, every colony we have is packed in chaff hives—each having five or

six frames of sealed honey. Every comb is held up to the light; and if its contents are not clear of dark honey, or last year's honey-dew, it is rejected, and saved for spring feeding. The Hill device is placed over the center of the brood-nest, with its backbone parallel to the frames. Over this is next placed a sheet of burlap, a trifle larger than the inside dimensions of the chaff hive. A layer of loose chaff, two or three inches deep, is then strewn over—dished in the center, and deeper around the sides, to allow for the convexity of the chaff cushion which is placed on top. This arrangement, while it permits the escape of moisture, renders it impossible for a cold current of air to blow around the cushion into the swarm.

We have now just 186 colonies packed in this manner, after doubling up. It was in just this way that we wintered our bees last year, with, however, the exception that they now have honey instead of sugar stores.

WHICH IS BETTER, WHEAT OR OAT CHAFF?

We very much prefer wheat chaff to oat chaff, as the former seems to be a better absorbent, while the latter, though possibly equally good an absorbent, does not dry out. Colonies last year that had the oat chaff did not winter nearly as well; the chaff was wet and moldy, and had become matted down. On the contrary, the wheat chaff was nice and dry. So this year we have nothing but wheat chaff on all the hives.

ERNEST R. ROOT.

TWO QUEENS IN A HIVE.

ALSO SOME KIND WORDS.

THE goods shipped as per my last order (by mail) were duly received. Thanks for your prompt attention. All goods came to hand in first-class order. The hammers, No. 3, I consider the prettiest I have ever seen, both in size and finish; and the little planes, price 15 cts., are regular "daisies." In fact, I would not take a dollar for mine, and do without it. You can say to all carpenters, that these planes are just the handiest siding plane they can get, as one can be carried anywhere in the apron pocket, and no matter if you are at work on a scaffold, you have your plane with you. I am a practical mechanic, and know whereof I speak.

I have something to report which I never heard of before; that is, two young queens, Italians, remaining in the same hive for one season, laying peaceably side by side. The facts in the case are as follows: Last April a fine swarm of Italians came out of the hive and were duly hived. The seventh day, being on the lookout, I heard a piping in the hive (the parent stock), and of course I kept a lookout for a second swarm, which came about the 12th day. I noticed, in hiving the swarm, that there were two fine-looking young queens with it, both of which went in with the swarm. I kept a close watch, expecting, as a matter of course, that one of the queens would be killed; and as I never found a dead queen in front of the hive, I supposed that energetic workers had carried the extra queen clear off, so I gave the matter no further thought.

A few days, in looking over my hives I lifted out a center frame from the above-mentioned colony, and there I found two fine-looking Italian queens on the same comb, not two inches apart. How do you account for it? I can not find a similar

case mentioned in any of the bee-books, and I have "Langstroth on the Hive and Honey-bee," and have read the A B C, also a good many bee-journals. I can find cases mentioned of two queens in one hive—an old one and young one, but never two from the same lot of queen-cells. The queens are both good, as I have taken one of them and introduced her to a colony of hybrids, and she was well received, and both colonies are doing well.

Gonzales, Tex., Nov. 2, 1885.

M. BROERS.

Thanks for your kind words in regard to our little plane and other things, friend B.—Although cases are rare, where two queens of the same age remain peaceably in one hive, yet they have been mentioned in our past volumes; and it has been suggested, that, by selection, we could secure a race of queens not hostile to each other; and I confess that I can not see why the task is much more difficult than securing a strain of poultry that never sit.

LOSS OF QUEENS ON THEIR WEDDING-TRIP.

ALSO CAUSING THEM TO TAKE THEIR FLIGHT BY FEEDING THE COLONY.

WHILE attending the Kentucky State Bee-Keepers' Convention I heard the subject discussed in regard to the loss of queens on their wedding-tour. It was decided that it was owing to the disposition of the bees, which I think is true, as I have twice observed the bees balling their queen at the entrance, immediately on their arrival from their wedding-trip. Nothing was said in regard to a remedy for this. A few years ago I thought I had made quite a discovery, when I could induce my virgin queens to take their wedding-flight, even when the weather was not favorable, by tilting the hive back and pouring in half a wine-glass of syrup on the sixth day from the time of hatching. But when I read friend Alley's book I saw that he had made the discovery, instead of me, although he uses a feeder, to which I object. I do think, if you are careful in feeding so as not to attract robbers, that the feeding temporarily changes the disposition of the bees, and thus the life of many a queen is saved. This is according to my own observation, as I have very few losses since I adopted the above plan.

My nucleus hives consist of an extra box, such as is used in the upper story of the L. hive, with three permanent division-boards, permanent bottom, and a cover, two L. frames to each compartment, and one entrance at each side, and one at each end, two pieces of enameled cloth to cover the frames; thus any part can be examined without disturbing the others, and twenty-five such boxes are sufficient to run one hundred queens.

WINTERING.

I use the L. hive as friend Muth gets them out, with the extra box and ten frames in the upper story. I have had the best results when I leave this extra box on all winter with abundance of good honey, and the entrance-blocks away. A burst of sunshine does not make them rush out, and a cold wind can not reach the cluster. My objection to the above plan is, that so few have adopted it. I should like to hear from others who have tried it. Those that are not prepared as above are packed

with chopped oats straw. Our honey-board is in three sections. Take out the center one, move the other two toward the center, so as to leave one inch open over the ends of the frames, and about four inches open at the center; now lay the other board across the center, at right angles, and spread over all a piece of burlap. Pour in four inches of straw. I consider this an improvement on the Hill device, as it ventilates all around, yet holds the warm air directly over the cluster.

—WALT. S. POWDER, 50.

Groesbeck, O., Nov. 6, 1885.

Friend P., this plan of inducing the queen and drones to take their flight when the queen is of a proper age, by giving the colony or nucleus a feed of warm honey, is a very old idea. It was first given us by the Germans, and with some other features for getting Italian queens and Italian drones to take their flight while common drones were not on the wing, was called the Hobler method. It was a good deal discussed, and seemed to be finally dropped by universal consent. I do not remember, however, that the point was brought forward, that queens induced to fly this way were sure to regain their hives safely.—In regard to your plan of wintering, friend P., I agree with you, that plenty of ventilation, both at the entrance and over the bees, seems to be one great factor in succeeding.

THE WIDTH OF AN ENTRANCE.

THE COST OF STOPPING HEAVY MACHINERY.

A LETTER from Mrs. L. Harrison says that I did not tell all about Mr. Rufus Porter's winter management of bees, in Lewistown, Ill.; that I did not tell how much lower ventilation he gave them. Mr. Porter contracts the entrance to $\frac{3}{4}$ x 3 inches, and pays no attention to the snow at the entrance, unless there should be a sudden thaw, and the snow should get in the way of the bees flying out. He says, that when the entrance faces to the south there is not much danger of snow or ice clogging the entrance. The way he packs his bees, they would have plenty of air with the entrance entirely closed.

Yesterday, Mollyony and I started out to find apples and cider to make our supply of apple butter. Apples are very scarce and high-priced now, good hand-picked apples selling for \$1.00 per bushel; but we found some very nice snow-apples that had fallen from the tree, which we bought for 25 cts. a bushel. Then we went to the cider-mill. Now, the cider is made at the drain-tile factory; and to reach it we have to drive down a long narrow lane, past the graveyard on one side, and the slaughter-yard on the other; up a hill and past the factory, before we can turn around. Well, when we got just to the top of the hill our horses got frightened at some blankets that they use to cover the tile when it is drying, that were hung to dry near the road, and they pranced and reared and backed out, and lunged forward, and all the while the machinery in the factory that was grinding clay was uttering the most heart-rending groans and shrieks. It would go on groaning and clamping for a minute, and then, as if it had gathered strength for a grander effort, it would send forth one of those blood-curdling "scrouches" that seemed as if they would tear the

building all to pieces. Well, there we were, with a barb-wire fence on one side, and the hollow square on the other, where the machinery was, partly beneath the ground, and we were debating in our minds whether it would be better to be thrown on the barbs or down among the machinery, when they straightened out and went on all right. I drove as far away from the building as possible, and then left Mollyony at the horses' heads, while I went in to see about the cider.

The proprietor is very much of a gentleman. While measuring the cider (it was boiled down, three gallons into one, and I took home twelve gallons of cider in two two-gallon jugs), he told me all about his cider jelly. He has machinery on purpose, boils it with steam-pipes, and makes a very nice and cheap jelly. He runs it, while hot, into wooden buckets holding half a gallon, and covers them with a wooden lid put on with a twist so that it will not come off unless untwisted; he sells the bucket and the half-gallon of jelly for fifty cents. The jelly contains nothing but cider. He turned the buckets upside down, and the jelly never moved.

Pretty soon after we got there the machinery stopped; but before we were ready to go away it started up again with all its horrid noise. I asked him how long runs they made, and he said they would not stop again till dinner time, unless something got wrong with the machinery. I told him that I was in hopes they would stop about the time I started home, as the horses were afraid of their noise.

"Oh!" said he, "we will stop till you get by. Almost all the horses that come here are afraid, and we have to stop till they get away."

Then he spoke to the engineer, and before I had got in and turned around the dreadful noise had ceased, and I drove by the building all right. He went and took down the blankets (I had told him about them), and I had no more trouble.

Here is the point that I want to make: He stopped his machinery to let me get away, and he said he did it often. I suppose the stopping and starting-up took him five or eight minutes; and while it was stopped, all the men and boys stopped too. There seemed to be ten or fifteen of them, and he pays the men, I suppose, about \$2.00 a day. If they stop half a dozen times in a day his loss must be considerable. Now, if I were that man I would have the road clear on the other side of the lot, as far away from the noise as possible, and I would have a road twice as wide, so that horses might prance around a little without having to climb a wire fence or fall into a hole. I think it would be money in his pocket, besides being so much safer, as they never see the incoming teams in time to stop for them, but only the outgoing ones.

I had no idea, when I ordered those division-boards sent "in the flat," that they would be all in little strips. I expected a board and a top strip to hang them up by; but I ought to have known that no man could sell a solid board of that size for six cents. I had some fun nailing them together. I suppose that your men in the factory, with their work-benches, and clamps to hold them level, and the right-sized nails, and a good hammer, could make twenty-five of them in an hour; while I, with my best licks, could make only four in 40 minutes. In the first place, I could not get any nails that were just right. Nails large enough to stand the strokes

of the hammer would split the wood; the slim nails bent over, split open, and went crooked, so that about half the length came through on one side or the other. The old hammer was too heavy, and the new one too light, and I am fully persuaded that I do not know how to drive a nail. I succeeded, however, in making twenty of them hang together, and I then stopped to let my blue finger-nails and blood-blisters get well before I make the rest.

MAHALA B. CHADDOCK.

Vermont, Ill., Oct. 15, 1885.

Mrs. C., you are mistaken about the things that our men make. The division-boards are made by girls, and they have no tools except an ordinary heavy solid table, hammers of the proper weight, and nails exactly the right size. They have, however, had experience in driving these nails into the thin boards, so they will go right along with it as fast as they can drive, and they rarely have a nail come out at all. I would refer you to the remarks in regard to hammers and nails, on page 16 of our price list. One of our three-cent hammers answers very well for this work, but we must have nails of the proper size. Your experience illustrates what we have so often talked about—every one to his trade. But it seems to me that every bee-keeper ought to practice nailing until he or she is tolerably expert, and then you must have a good assortment of nails so you can choose just the proper one for the proper place. I would have at least three hammers for like reasons. We can furnish whole boards as cheaply, but they would warp and twist; whereas the narrow strips, when properly nailed, will stand dampness and sun, without checking or splitting or warping.

GALVANIZED WIRE CLOTH FOR OUT-LETS TO FISH-PONDS.

FRIEND PEIRCE GIVES US SOMETHING FROM PRACTICAL EXPERIENCE IN THE MATTER.

STEEL wire cloth, like sample, is kept in stock by dealers here for miscellaneous uses. I tried it for screens on sluices of hatching-ponds. At the first drainage of ponds it clogged very quickly; and upon cleaning with an ordinary scrubbing-brush it broke like straw paper; and but for a dip-net at hand, which we placed over the break, we should have lost our few small carp at a time when they were very valuable. Two months, when connected in this way, especially if one is zinc, will, when kept immersed in water, produce galvanic action, which will disintegrate one or both metals with greater or less rapidity according to the chemical ingredients held in solution in all water. In most of the waters of this region, galvanized iron "rots" rapidly. The sample which you send would become worthless within from four to six months. For fattening-boats or vats, the mesh is as near right as can be gauged; but the size of wire, which seems to be 25 plate-gauge, is many sizes too small. It should be not less than 18 gauge for a stiff and durable bottom. Screen, woven of that size of wire, can not be reduced to quite so fine a mesh as I could desire; but when heavily galvanized, the mesh will be sufficiently close to hold most kinds of food necessary for carp, and certainly the finest kernels of corn, when

expanded by boiling, and it is not probable that any cheaper food for fattening purposes can be found. Philadelphia, Pa. Nov. 9, 1885. M. P. PEIRCE.

Thanks, friend Peirce, for your very kind suggestions; but I feel quite certain that the waters of our vicinity would not affect this galvanized steel wire so as to cause it to rot in so short a time. I have been acquainted with the use of galvanized wire cloth for such purposes for a good many years, and I can not remember that I ever saw any that seemed to be wasting by age, even when kept under water. If I understand you, the heavier wire cloth is no better, only that it contains so much more metal that it would take a much longer time to dissolve away the zinc, and expose the iron or steel to the action of the water. We should be very glad indeed of reports from those who have used galvanized wire cloth for such purposes. The friends will please bear in mind, that *tinned* wire cloth and *galvanized* wire cloth are quite different articles. We have always objected to the use of galvanized wire cloth, or galvanized iron in any shape, for honey-extractors, or any thing of that kind, because the acid in the honey attacks zinc so quickly, making the honey unwholesome if not poisonous.

BOILED CORN FOR FATTENING CARP.

I am glad to know that you decide that boiled corn is the cheapest food for fattening carp. Ours take corn with avidity, after it has been soaked in water a day or two. A correspondent of the *Ohio Farmer* suggests placing the soaked corn on a little platform about six inches below the surface of the water. I can readily imagine the antics the larger fish would make in coming for their feed. We boil corn for culinary purposes very rapidly and cheaply by means of steam. The corn is put into a large deep stone jar, and a rubber hose connected with the steam-pipe goes down through the corn to the bottom of the jar. A large quantity can be boiled soft in a short time by this means.

HUNTING BEES ON THE ISLAND CALLED "BEES' NEST."

ALSO SOMETHING ABOUT FALSE STATEMENTS IN REGARD TO THE ADULTERATION OF HONEY.

IHAVE just received a visit from Antone Sweetser. He lives near the island on the Muskegon River called the "Bees' Nest," of which I have written before. It is interesting to hear him relate the almost incredible finds of honey there. Last summer, he says, he was hunting bees, and found the tree and a large cluster hanging on the outside. Thinking a new swarm had tried to enter a cavity too small to hold them, he thought them worthless, and so informed the family; but in about two weeks the boys insisted on cutting the tree, which they did; fortunately it fell on another small tree, and fell easily. Mr. Sweetser chopped in through the thin shell directly into the honey, and soon there was half a bushel of bees on the outside. They then got the crosscut saw and cut out a log eight feet long, mostly below the hole, and he says it is solid honey; in fact, he said there was a little honey above and below where they cut. They set it on end, and a few days later

they took the team, and now have it at home in good shape. He said they were flying nicely when he left home. I tried to buy them, but I could not. He finally said he would sell them after they swarmed next year.

Last fall, he says, they cut a tree and took with them a wash-boiler and two 14-quart pails, which they filled. Not getting it all, they returned next morning, and further up the tree they took out 60 lbs. more of nice white honey, by actual weight.

There is a number of Indians living near them, and he says that Indian John found in a large sycamore-tree, three swarms—one in the body and two in the large limbs. He declares, that from the body of the tree alone they took 300 lbs. of honey.

Mr. Sweeter is one of those whole-souled Germans whose veracity none can doubt. He makes me think of friend Muth. He has been keeping bees in box hives in the past, but has now ordered an outfit of chaff hives, and says he shall adopt the modern appliances. He had never seen foundation or a smoker until to-day. He carried home with him a Clark cold blast—the best extant for the money.

And now just a word in regard to "false statements in regard to the honey business of the country." I want to add \$500 to your \$1000, and let other bee-keepers fall in until we make it a million, and then let some of those disgruntled liars show us where they make and sell comb honey, where neither wax nor honey is used, and become a millionaire. I have had some annoyance and am mad. At some other time I will tell you about it, and how it came out.

Fremont, Mich., Nov. 9, 1885. GEO. E. HILTON.

Friend H., will it not be a good idea for somebody to start an apiary on this Bees' Nest island?—About false statements in regard to our honey, Neighbor H. says when they get their machinery perfected for manufacturing eggs, they will probably succeed in making comb honey.—Thanks for your additional \$500. I think the idea is a good one, and the investment is certainly safe.

MORE ABOUT 541 LBS. OF HONEY FROM ONE COLONY.

A GOOD SHOWING FOR ARKANSAS; SEE PAGE 754.

THE hive that made me 541 lbs. of honey is 41 inches long, 31 inches wide, outside measure; 40 frames in the lower story, and 40 above. The lower story is divided by two division-boards, which the queens can not pass; then four zinc honey-boards over them, making a perfect fit, and there are four separate queens. The bees are all together in the upper chamber. Each corner of the hive has an entrance. This hive is worth six single ones. A. L. LIGHT.

Grove Land, Arkansas.

Well, well, friend L., and so it transpires that it is *four* queens instead of *one*. Now, we might call it *four colonies* instead of *one*, were it not for the fact that the bees all work together. Although they do work all together, yet I am inclined to think they carry on business as four distinct colonies of bees. But if they continue to do so without any quarreling, or loss of queens, it is certainly something very strange and unheard of. I have known such arrangements

to prosper while the yield of honey was good; but when bees begin to rob, my experience has been that the queens will all have to go, but one.

THE WESTERN BEE-KEEPERS' ASSOCIATION.

QUESTIONS AND ANSWERS.

THE fourth annual meeting of the W. B. K. A. was held in the court house at Independence, Mo., at ten o'clock A. M., Oct. 15, 1885.

President A. A. Baldwin, of Independence, Mo., occupied the chair. The morning was taken up with the order of business. Report of secretary was read and adopted. The committee appointed by the North American Bee-Keepers' Society said that the following railroads gave first-class freight rates on honey in glass, and third class on extracted honey: A. T. & S. F.; M. P.; U. P.; and H. & St. Joe. The committee also suggested, that inasmuch as the transportation companies hold monthly meetings, a committee be appointed that has more time than the present committee, to prosecute the business further, by visiting these meetings; and, if possible, obtain a better schedule for bee-keepers.

The association next proceeded to elect officers for the coming year. E. M. Hayhurst, Kansas City, Mo., President; R. B. Leahy, Higginsville, Mo., Vice-President; James H. Jones, Buckner, Mo., Treasurer; and P. Baldwin, Independence, Mo., Secretary. The remainder of the morning session passed pleasantly in discussing several interesting topics relative to bee culture. There being no further business, the president appointed a committee to prepare subjects for the afternoon's discussion, and the association adjourned to 1:30 P. M.

AFTERNOON SESSION.

The association was called to order by Pres. Hayhurst, at the appointed time. Several ladies took seats with the bee-keepers; and although they took no part, they were very encouraging listeners.

The committee to prepare questions brought out the following, which were taken up in order:

Does it pay to feed extracted honey, in order to produce comb honey, and what way is best?

Mr. Conser.—"I think it takes about 3 lbs. of extracted honey to get one of comb, and I do not think it pays. I feed by tipping the hive back and pouring the honey in at the entrance. I do this at night."

L. W. Baldwin.—"I feed only to get unfinished sections completed, which can be done just as the honey harvest is closing, and not allow the bees to stop comb-building. There is money in it if carried out in this manner."

A. A. Baldwin.—"I have fed extracted honey for this purpose, and think it pays, but I have not tested it by actual weighing and experiments."

Which race of bees is best to keep, for the purpose of getting comb honey?

R. B. Leahy came forward with a plea for the blacks as far as getting white capped and finished-up comb honey for market. "I think they enter sections more readily before swarming, and are less disposed to swarm. All things considered, I prefer the Italians."

James H. Jones.—"I would not keep bees if I had to keep the blacks." Here the discussion was quite animated, in bringing out the different traits of the two races, but the association came down solid for the Italians. Other races of bees were spoken of, but no one had handled them sufficiently to be very enthusiastic over them.

What is best to winter bees?

L. W. Baldwin.—"I winter my bees in the cellar, and have found by the scales that, on an average, bees consume from ten to twelve pounds more honey per colony when wintered on the summer stand than when wintered in the cellar. This is quite an item in wintering a large apiary."

A. A. Baldwin.—"I think that outdoor wintering brings the bees through with more vigor, and they usually swarm earlier. I feel confident, that bees packed with chaff will consume at least 5 lbs. less honey than if not."

Pres. Hayhurst.—"I think chaff packing saves stores."

The general opinion was, that bees wintered on the summer stand could be crowded on to as few

combs as they can occupy, with 20 to 25 lbs. stores, and well packed.

Does it pay to use reversible frames and section boxes?

No one present had made any use of them, except Mr. Conser, who had used them, and was well pleased with them.

How far from each other should large apiaries be located, in a good honey country?

This question brought out, from several of the members, statements of long flights of bees in search of honey; but the opinion most generally accepted was that, if placed not less than four miles apart, there would be no conflict.

Association closed till 9 o'clock next morning.

The association met at 9 o'clock. The president not having arrived, Vice-president R. B. Leahy took the chair. L. W. Baldwin was selected to prepare the table of statistics. There being no other business to be transacted, the list of questions was taken up.

Does it pay the trouble to use wired frames?

A. A. Baldwin.—"I have had but very little experience with them, but all I have examined showed the wire."

John Conser.—"I have used them. Where a man is shipping bees, I think they are a great benefit. In handling combs at home they are not of so much use."

L. W. Baldwin.—"I have had, probably, as much experience as any one present in handling and moving bees for several years, and in all that time I have not had half a dozen combs injured, even if transported without springs; and as far as I have observed, I can not see any use for them."

R. B. Leahy.—"If I were going to run for comb honey, using a frame with a short top-bar, I would not use them. In handling, I would rather have them wired, especially for the lower story."

How can we remedy the turning-out of the starters in the sections, as the bees work them?

This question called out the experience of this season of several leading bee-keepers, and it was generally thought that the cause was the slow flow of honey, cool weather, and colonies light for bees. Some advocated using smaller starters, others turning the sections around, while others thought, that to crowd the bees would remedy it.

What direction is best to have the hives face in winter time?

R. B. Thorn.—"I would have them face the same way, summer and winter."

S. W. Salisbury.—"I have loose bottom-boards, and raise the hive in summer, and prevent the bees from lying out, and let them down on the bottom-board in winter. I think the hives should face the south."

How should young swarms be handled, to secure the largest amount of honey?

L. W. Baldwin.—"I make a nucleus from the swarm, and put the rest in the parent colony."

A. A. Baldwin.—"A good way is to shut the swarm on five or six frames, and compel them to go into the sections at once."

Is there any successful way of introducing queens?

E. M. Hayhurst, having made the statement that he could introduce five hundred without the loss of one, was called on to give his method, which is as follows:

"After making the colony queenless I have a young queen caged in a Peet cage, and I place the cage directly over the cluster of bees, and leave it there till I see the bees are perfectly reconciled to the queen. This will take some two or three, and, sometimes, several days. I then remove the queen-cells and place the cage on an outside comb over some honey; remove the slide, and rim out a plug through the comb, letting the plug remain in place, and leave it undisturbed for a week. If the bees are disturbed before the queen begins to lay she will become frightened, running and piping, and the bees will chase and kill her. The important point is to have the bees reconciled, every cell out, and no robbing."

L. W. Baldwin.—"I have found that colonies long queenless are very difficult colonies to introduce queens to—almost impossible with me."

Adjourned to 1:30 P. M.

Closing session, President Hayhurst presiding. A member handed in the question, "What is the most simple, cheap, expeditious way for the practical bee-keeper to change his stock by requeening?"

L. W. Baldwin.—"I put in cells after the colony

has swarmed, and again immediately after the honey harvest, by taking the queen from the colony, and the next day give it a queen-cell."

A. A. Baldwin.—"I would just as soon as not have my colonies queenless for twenty days after the honey harvest, and would take this time to give them a queen."

S. W. Salisbury.—"I requeen with swarming-cells."

The question, "Is it advisable to clip the queen's wings?" brought out a lively discussion.

J. H. Jones.—"I prefer to have my queens clipped."

S. W. Salisbury.—"I have tried clipping the queen's wings, and I think it induces the bees to supersede the queen immediately. I also have a great deal of trouble in finding a clipped queen when swarming."

L. W. Baldwin.—"The ease and facility in handling swarming is much in favor of clipped queens. I like the practice."

A. A. Baldwin.—"I do not think that clipping the queen's wings causes the bees to supersede her. The past season with an apiary of 135 colonies, only two were superseded, and they naturally."

A great majority of the members practice it.

James D. Mendor was appointed to endeavor to get a better schedule on apianian products, of the railroad companies.

Adjourned, to meet in Kansas City, at the call of the executive committee.

W. B. Thorn, of Glenn, Kan., had on exhibition a colony of Holy-Land bees.

Mr. John Conser, of Glenn, Kan., made a display of extracted honey. There was no general display.

The following is the number of colonies of bees, pounds of honey and wax, represented:

No. of colonies last fall,	1,528
" " this spring,	1,138
" lbs. comb honey,	33,557
" " ext'd,	10,285
" " WAX,	196

P. BALDWIN, Sec.

BEE BOTANY,

OR, HONEY-PLANTS TO BE NAMED.

PLEASE tell the name of flower inclosed, as it is good for bees. I have a single stalk of it that the bees cover and fill up very quick.

Dennison, O.

CHAS. L. HILL.

PRIVET.

Here are four honey-plants. Can you tell me their names? The first is called by some, privet. Whether it is the same as that described by J. L. Gregg, of Arizona, or not, I can't tell. It blooms afresh after every rain in summer.

BEE-BUSH.

This grows among the rocks on the mountain-sides; grows from three to five feet high; is blooming now. The bush has a peculiar odor, but not unpleasant.

CATCLAW.

The next is what we call catclaw, but I am told it is not the same as that found in Southern Texas.

WILD SAGE.

The last is what seems to be a kind of wild sage. It has been blooming for some time, and the bees are gathering pollen from it. It grows in abundance here, and looks more like sage than any thing else.

Burnet, Texas.

C. W. HARDY.

IMPORTANCE OF SENDING COMPLETE SPECIMENS.

I can not find time to determine accurately the names from such poor specimens. The one from Chas. L. Hill is an aster (*A. prenanthoides* [?]). Of those from C. W. Hardy, one is of the order *Labiata*, probably *Mentha*; two are leguminous plants—the one with prickles, probably *Schrankia*. The other I do not know.

W. S. DEVOL, Botanist.

Agricultural Station, Columbus, O.

A REVERSIBLE HIVE AND HONEY-BOARD.

REVERSING THE HIVES INSTEAD OF REVERSING THE FRAMES.

HAVING read with interest the article in Sept. 15th number of GLEANINGS, entitled "Friend Shuck's Reversible Honey-Board," and because it is very similar to ours, we write to describe our reversible honey-board devised last January, and which we have been using this season with good results.

It is made entirely of wood, composed of alternate slats of pine and basswood, $\frac{1}{4}$ in. thick—see cut. The pine slats are $\frac{3}{4}$ inches wide, and are straight; the basswood are $1\frac{1}{2}$ inches wide, and have 5 insets cut in each edge (scant 3.16 in. deep), like those in section boxes, by means of a cutter-head, so that, when each alternate slat is placed together, first the straight, then the notched, as shown in cut, to form the honey-board, it makes the proper openings through which the bees may pass to the sections, or frames above, but excludes the queens and drones.

These insets in the basswood slats do away with the necessity of spacing and nailing each slat separately. You will notice, by examining the above cut, that the slats are held together by end-pieces, having a $\frac{1}{4}$ -inch groove cut in the center of each, and the honey-board is put together as follows: Put in first a straight slat, and nail to each end-piece, then drop in the groove each alternate one, until full, nailing the last one, and you have it. The honey-board is reversible, therefore it makes no difference which side is placed up, when putting it on the hive.

THE IDEAL REVERSIBLE HIVE.

The cut illustrates our modification of the Simplicity; we call it the "Ideal" reversible bee-hive, because the body is made of pieces, so rabbeted on the inside as to be, when nailed together, just alike at top and bottom. Now, by fastening down the frames, by means of a strip, $\frac{3}{4} \times 1 \times 15$ inches, laid across them near their ends, and screwed fast to the effect in the sides of hive, 10 suspended frames may be reversed at once by simply turning the body bottom side up. When so reversed, the honey-board and case, or the honey-board and another body, will go on just the same as if it had not been turned over. This makes it possible and practical to reverse our suspended frames already in use, without the trouble and expense of adding reversible attachments to them. Of course, reversible

frames can be used in this hive as well. The case illustrated above holds three rows of ten each, $1\frac{1}{2}$ -inch sections (making 30), with nine wooden separators, or 23 $1\frac{1}{4}$ -inch, without separators, and is made on the same principle as the body, and therefore reversible. The two strips running lengthwise at the bottom have a projection of tin to support the sections, while two similar strips at top are movable, being held in by a loose wire nail put through the ends of the case. The bodies, with a honey-board between, can be tiered one above another, as also the cases; or a case can go next to the bottom; and a hive with a honey-board between can be placed on top, just as one sees fit. This, we think, makes a practical working reversible hive, meeting the most of the advancing modern requirements; viz., reversible body and frames, reversible honey-board; reversible case and sections; reversible top. Are these points of any value? We have others in the above hive not mentioned. If you wish to examine a complete hive, we will send you one.

HEMPHILL & GOODMAN.

Elsberry, Mo., Sept. 21, 1885.

P. S.—The cut is not accurate in all its details, but fairly represents matters; for instance, the entrance is shown as if notched in the body of the hive, when in reality it is made just like the Simplicity, by pushing the body back and forth, the alighting-board being offset $\frac{3}{8}$ inch lower than the bottom-board. The honey-board, as shown in position between the hive and case, is not well represented, besides showing a notch in the end piece (projecting upward), as if it were in two pieces, when it is not.

Since writing the article we have improved upon the method of holding down the frames while the hive is reversed, so as to obviate the necessity of nailing or screwing the strips down, as spoken of in said article. The improvement consists in having a wobble saw cut made in each side-piece of hive on the inside. The wobble cut is made on the same plan as the handholes in the body and case, only not so wide, being but $\frac{1}{4}$ inch. This permits the strips used to hold the frames down, to be $\frac{1}{4}$ or $\frac{3}{8}$ inch longer, and they are simply pushed into these slots, which securely holds them, without the necessity of nailing or screwing—a very great improvement.

H. & G.

Friends H. & G., it seems to me there are some very important features in the hive you mention; but if I were you I would go a little further and have frames made without any projections at all to the top-bar. May be, however, you are doing that, but you don't say so. Then you can lift the frames out when the hive is one side up as well as when it is the other side up. There are grave difficulties in the way, however. The frames must be at fixed distances, for all I can see, unless we have a good many complications, and they must also be held in place the right distance from the end-board, and at the same time we want them easily removable. I do believe, that reversing the hive is going to be the readiest method of reversing the frames; but to do this we want to dispense with the projecting-end top-bar, as I have

mentioned. May be we shall never succeed in making it practicable; still it seems to me as if we ought to. The cover to your hive is substantially the same as Heddon's. Your method of making a slatted honey-board, I think, is more expensive than to cut suitable perforations in the board—at least so far as expense is concerned. Even if we don't adopt these various devices, I think it is an excellent plan to take a look at them, and consider well what is being done.

THE SHEEP-BEES LAWSUIT.

ALL'S WELL THAT ENDS WELL.

WE extract the following from the *A. B. J.* of Nov. 4:

The sheep-bees lawsuit was "called" at the Circuit Court in Richland Centre, Wis., on Wednesday, Oct. 28, 1885. It was dismissed by Judge Clementson, who decided that there "was no cause of action," and the jury was discharged. It may be argued before the Supreme Court, and should that Court determine that there is a "case," then it may come to trial on the ruling of the Supreme Court. The Bee-keepers' Union made such a stir, and showed such fighting enthusiasm in the matter, that the Judge made a thorough examination of the laws of the State and concluded that there existed no laws or rulings upon which he could instruct the jury.

We think that the bee-keepers of America have cause for pride in the success that has, so far, attended their efforts in this matter.

We shall watch the matter closely, and checkmate any move that may be made by the complainant, and now, at the close of the first combat, let us all jubilate.

Since this matter is so happily disposed of, we presume the bee-friends of the world at large may now take a long breath, and settle down easy—at least so far as any trouble on this score is concerned. Instead of lying awake nights, deciding as to whether or not they shall give up the business, we presume they will get all ready for next season's operations, with a broad smile on their countenances, not unlike the friend below.

"G-O-O-D M-O-R-N-I-N-G."

Below is an extract taken from a proof-sheet kindly sent us by the editor of the *A. B. J.*:

Opinion of the Court—Judge Clementson.

The Plaintiff, by attorneys, claimed that bees may trespass as well as other animals; that the bees of defendant came upon the premises of plaintiff and drove the sheep from the pasture; that it became a nuisance that should be abated, as other nuisances are, etc.

The Court—Is your claim for literal trespass or for nuisance?

Plaintiff—It is a trespass that becomes a nuisance because of the vast number of bees kept.

The Court—Have you any authority on this matter?

Plaintiff—We have none.

The Court—If you proceed upon the theory of nuisance, will you please tell where the nuisance exists—will you locate it?

Plaintiff—The bees were kept upon defendant's premises, and by him upon a farm joining plaintiff's premises, and they became a nuisance by coming upon the plaintiff's premises in vast numbers. This nuisance should be abated, as a bad stench should.

The Court—The stench is essentially bad, and may become a nuisance by being blown by the wind—it depends where it is located. Bees are recognized as useful. If you proceed upon this theory it will establish a new line of liability, and it is advisable at the outset to find its exact course.

Plaintiff—It is the maxim of law, that one person shall keep his own property so it shall not injure others. We claim that the defendant kept bees that injured the plaintiff's sheep—drove them from the pasture so they became weak and feeble, many of them dying during the following winter.

The Court—You do not allege that the bees stung the sheep, nor do you allege that they took any thing from the clover of value to the sheep—you simply assert that the sheep were driven from the pasture by the bees. We must understand whether you proceed upon the theory of trespass or of nuisance, so the nature of the damages may be determined.

Plaintiff—The theory of the prosecution is that of trespass. The presence of the bees upon the plaintiff's premises was voluntary. The nuisance lay in their vast numbers. By the new methods of bee culture the multitude kept in one place vastly exceeds those formerly kept. The bees are moved from place to place in quest of pasturage.

The Court—A man may pass over his neighbor's farm a dozen times, and he does not bring suit for trespass. Now if a man has a hive of bees, and it is trespass for them to go upon others' property, he would be liable to suit for trespass wherever a bee went. *It would fill the courts!* Every bee-keeper would have a "peck of trouble!" It would seem that if the sheep were driven from the pasture in the summer they might have been fed up in the fall to recruit them for the winter. I can see that, upon your theory, even flies would in certain cases become a nuisance for which a man might be prosecuted. Suppose the owner of a cane or sugar mill should locate it near a neighbor's property, and vast swarms of flies came to feed on the sweets, they might be a nuisance to stock in an adjoining field. If we proceed, it would be difficult to determine the extent of damages.

This case involves new points in law upon which there are no rulings of the Supreme Court. We have no law upon which to instruct a jury. I have made some inquiries to satisfy myself. As we must look to the Supreme Court for rules of law, it is better that this case be sent there at once. If the defense objects to any evidence under this complaint, the objection must be sustained, and the plaintiff may appeal on the ruling thereon.

The defendant objected as suggested, and the objection was sustained by the Court, and the plaintiff accepted.

HOW FAR WILL A QUEEN FLY TO MEET THE DRONE?

ANOTHER EXCEEDINGLY VALUABLE CONTRIBUTION TO OUR BEE-LITERATURE, FROM FRIEND MARCH.

I DON'T think that fact has been established yet; if it has, I have never seen it in print. I believe I established the fact, without the shadow of a doubt, that worker-bees would, in a scarcity of honey, fly 6 or 7 miles, or even more, for forage. See my articles in *GLEANINGS* for 1882, April No., page 181; again, Dec. No., page 589. I now have discovered how far a queen can fly, or, rather, how far one has flown; or, I should say, how far apart two hives can stand, and one furnish queen and the other drones, and the queen become fertile. Perhaps it would be interesting to some of the readers of *GLEANINGS* to hear my experience in queen-rearing.

In the spring of 1882 I sent to A. I. Root for Italian queens, and Italianized my apiary. Now, one and a half miles west of me a neighbor had three swarms of black bees. To keep my bees pure, of course I must Italianize his swarms. There comes in the first strange freak. I took out the black queens and gave each, 48 hours after, a cell from my best Italian swarm. At the same time I made four nuclei and safely introduced a cell to each. It being September, and no honey coming in, most of the drones, except in the hive where the cells were raised, were destroyed. We took pains to open the black swarm, and to kill every drone found, so as to make a sure thing of purity in mating. Now, mind you, his queens were $1\frac{1}{2}$ miles distant, while mine were in the same apiary with the drones. One would naturally suppose that the chances were two or three to one in favor of my queens becoming fertile. The fact is, that only one of mine became fertile, while all three of friend Crandall's, $1\frac{1}{2}$ miles distant, met the drones and commenced laying inside of 13 days after hatching, and proved to be purely mated. It seems that three of mine preferred to remain maidens rather than meet a drone belonging to the same family. I kept the three for 24 days, fed half a teaspoonful of syrup each day, but had to destroy them and double up the nuclei.

From the above it would seem that it is the queen that flies a distance to find the drone, rather than the drone flying in search of the queen. Perhaps nature has so ordered it, that there shall be no in, or close breeding. There was no difficulty about their flying, for the 14th or 15th day I threw them all in the air, in front of their hives (in the middle of a warm day), and they took wing and flew finely, and all three found their way back to the hives. One was gone 35 minutes, and was seen to return to the hive. Neither met the drone, and, in my opinion, because there were no drones at a distance to meet.

That winter, Mr. S. B. Best received a swarm of black bees in a box hive, as a present. They were set in his garden, just 27 paces from the corner stake of the section line of his claim, which is 7 miles in a direct line from section 28, where my apiary stands, and $5\frac{1}{2}$ miles from neighbor Crandall's three hives that I Italianized. The next summer, one of neighbor Crandall's young queens mated, and produced workers with one and two bands, and terrible to handle. That fall, friend C. disposed of his bees and they were taken from the island.

The next summer one of my queens mated. There was a study. Could one of my queens have flown 7 miles to meet the drone, or even half that distance? She had surely met a black drone somewhere, and there were no bees but Mr. Best's on the island, except my Italians. I finally settled it in my mind, that the black hive had cast a swarm, and they had come my way and settled in the woods within two or three miles of me.

This fall, 1885, I was out at friend Best's place for a few days' visit. While there he told me he had had the bees several years, and had not received a swarm of bees or a pound of honey from them yet, and asked me to open the hive and see if they could spare a few pounds of honey. Now you can judge what was my astonishment, when I came to examine them, to find as fine a swarm of hybrids as I ever saw. They had the peculiar characteristics of the bees where the black queen meets the Italian

drone. Part of the bees were perfect three-banded Italians, while part were black, like the queen. Here was no mistake. My drones must have met this queen, and she or they together must have flown 7 miles to meet, for neither myself nor friend Crandall ever lost a swarm of Italians, always keeping our queens clipped. Whether the queen flies to meet the drone or the drone to meet the queen, I can't tell; but between them they managed to make 7 miles, that I can prove; and more, every statement in this article I can prove by affidavit, if necessary.

H. A. MARCH.

Fidalgo, Wash. Ter.

Friend M., we are surely greatly obliged to you for the trouble you have taken to give us positive data on these unsettled points. Are we to understand that you are on an island, all of you? If so, you are situated in an unusually favorable position for such an experiment. My opinion is, that the queens will fly about as far as the drones, but that it may happen that the drone might go the greater part of the distance, or the queen the greater part; and it is not improbable that either queen or drone may fly as far as the worker-bees, say six or seven miles; but I feel quite certain they will all of them go a much greater distance over the water, or over a prairie, than they will over hilly or mountainous country interspersed with tall forest-trees. Many facts have come to light during years past, to indicate that drones and queens do go quite a long distance—I should have said from two to three miles in all directions. This, you know, would make a meeting possible from four to six miles; and with such a locality as yours, I should say seven miles might not be the *extreme* limit.

SOME ITEMS.

HOW AND WHY I CLIP QUEENS' WINGS.

I AM asked by several to tell in GLEANINGS how I clip queens' wings. The first thing necessary is a sharp knife. I use one, off A. I. Root's 75-cent counter, keeping the little blade sharp for this and other purposes. By the way, I find splendid stuff in these knives; for with one of them I have shaved myself, it doing the work equal to any razor. For clipping queens' wings I prefer a knife to scissors, for the reason that, with scissors, one is quite liable to cut off the legs of the queen, as she is apt to get a leg between the blades just as they are being shut. In clipping I catch the queen by taking the wings between the thumb and fore-finger of my left hand, when with my right hand I get out and open the knife. I now gently place the sharp blade of the knife on the wings of the queen, both hands being lowered to within an inch of the tops of the frames in the hive, when I carefully draw the knife a little, thus cutting the wings and letting the queen fall and run down into the hive. In this way the queen is not touched by the operation, and is never liable to be killed by assuming any strange scent from off the hands. The wings are also cut off, so but mere stubs remain, just as I desire to have them. There is no danger of cutting the fingers if you stop drawing the knife as soon as the queen drops.

WHY I CLIP.

The first reason is, to prevent the swarm abscond-

ing in swarming time, as I allow natural swarming. The second reason, and one perhaps equal to the first, is, that with queens clipped as above they are so readily found; for a bee with no wings among thousands with wings is quite readily seen. I verily believe I can find three queens which are thus clipped, to where I can find one not clipped. Third, swarming is conducted with more loss and less labor than is possible with queens having wings. Fourth, in case of the uniting of two or more swarms together I have absolute control of them so they can be separated at will.

CYPRIAN AND SYRIAN BEES.

After three years' trial of these bees I wish to say a few words regarding them. First, I find that in their purity they are so cross that it is out of the question for me to tolerate them. Smoke is only an irritant to them, unless used for five minutes before opening the hive, in large quantities at the entrance, in which case they will fill themselves with honey, and act like other bees. The hive can also be opened on hot days without the use of smoke, and all will go well if no jarring of the hive or any kind of a mishap occurs. If any thing of the kind occurs, woe betide the operator; as, for instance, I had been getting along nicely with my colony of Cyprians in the above manner, the past season, when one day a heavy gust of wind tipped over a frame I had stood outside the hive for a few minutes. In less than five seconds I was beset by a host of infuriated bees; and in spite of smoke or any thing else, before I could get the hive arranged and closed I received more stings than all I received during the season besides. Second, as soon as a colony of these bees became queenless the workers go to laying eggs, so that the combs are filled with drone brood, thus causing thousands of worthless dwarf drones to be reared, which is a positive nuisance, and a great drawback to them. Third, in this locality they do not begin brood-rearing in earnest until the main honey-flow arrives, when they breed to such an excess that much of what should be surplus honey is used up in brood-rearing. Especially is this true of the Syrians. For the above three reasons I have this fall banished all of this kind of stock from my apiary. From my experience with these bees crossed with Italians, I am led to believe that most, if not all, who recommend them have only Syrio-Italians, or Cyprio-Italians. Two or three years ago A. W. Osburn (now of Cuba) called on me, and was very strong in his praise of the Syrian bees, when, after some discussion, I showed him two colonies of pure Syrian bees. At this he exclaimed, "If those are Syrian bees, then I never had any." That crosses between the Syrian or Cyprian bees and Italians produce good bees, I am free to admit; but I can not see wherein they are any better than our ordinary hybrids, while I have reason for preferring our hybrids to them. Accordingly, another season will find my apiary entirely free from any trace of this blood in it.

G. M. DOOLITTLE.

Borodino, N. Y., Nov. 2, 1885.

Friend D., I believe your plan of cutting a queen's wing is a good suggestion; and I now remember, that in the absence of scissors I have sometimes done it with a knife in much the way you mention. The knife should have a very sharp edge, and the blade should be slender and tapering. I would suggest that this blade be used for no other purpose. Your reasons for clipping

are good; yet we dare not clip the queens we send out, for there are so many that might take exception, and we don't like to clip a queen just before caging her for shipment.—I believe your decision in regard to the Cyprian and Syrian bees accords mainly with the general feeling; although the trait they possess, of giving us unlimited brood on short notice, can often be utilized so as to make it very valuable, all things considered we may as well drop them.

AN ADVERSE REPORT FROM CALIFORNIA.

THE "BEE-LUNATIC" IN 1885.

HERE comes the "bee-lunatic" again—not with waving banners and beating drums, as he did in 1884. His drums are all muffled now, and his banners—inscribed with "Blasted Hopes"—are trailing in the dust. At the close of last season we had 115 colonies (GLEANINGS for Nov. 1, 1884, p. 738), of which 40 were below here, one mile. When we brought them home and opened them up there was a general fight. Do all we could, we lost 20 hives, so we had just 95 stands to begin on this season.

You remember I reported one ton of honey held over because it was not completely sealed up on the ends (we use eight section boxes fastened together, which we call a "box of sections"). Six of these boxes of sections go in the top story of our hives, and, when full, will weigh 84 to 85 lbs. I put this honey (fully a ton) on 25 hives. This was about 80 lbs. of honey to the hive. Now let it be understood, that each hive was booming full of brood, bees, and honey. If these bees had gathered five pounds of honey, and stored it, they would each have had their hive crammed full. They would have had no place to put any more. Each and every box of sections would have been completely sealed up.

Did they seal it? Well, you would naturally suppose they did—that they sealed it up in a few days, and then cried for more, wouldn't you? Well, I should; but they didn't—nary a cry. Right here is some promiscuous arithmetic. These bees worked hard for four months. I have lain down beside them, and watched them by the hour. They never even took time for dinner, but kept tumbling in and out of the hives the livelong day. Now the question is (and it puzzles all the arithmetic and algebra that I ever had any thing to do with), What did they do with the honey they gathered? It won't do to say they used it for brood-rearing, for they did not. There were but five swarms in the whole season, from the 95 hives. And by all means, don't tell me that these 25 hives of bees banded together to hoodwink and deceive me.

But here, you see, in the midst of all my pride and vanity they have knocked the stilts from under me, and left me groping in the darkness of night. What became of the honey they gathered? The other 70 hives—that had only foundation starters, made an average of 63 lbs. to the hive; that is, they gave us 420 lbs. in sections, and this is all we got. With comb honey at six cents, and it costing 14 cents per pound for sections, case, and hauling to town, if our hopes are not blasted, please state what will satisfy you in that line. Have we got to lose our whole apiary, nearly, like friends Heddon and W. Z. H.: to get our house burned down, to

furnish our horses with the epizootic, and be found ourselves, some morning, in the last gasp of expiring hunger, to get into "Blasted Hopes"?

This little insect that I have loved so well and praised so abundantly is a deceiver—a swindler and a cheat. He, she, or it, is a "fraud, a delusion, and a snare"—a robber, a thief, and a murderer. Now, you don't often read such plain talk in a bee-paper; but I just want the "little beast" to know exactly what I think of him.

THE HONEY SEASON IN CALIFORNIA.

The honey season here has been a very poor one. So far as I can learn, it is the same all over the State. You will have no great shipments of California honey to glut the markets *this* year. There was plenty of bloom, but there was no honey in the flowers. That was caused by an insufficient rainfall. We hope to do better next year.

A CLEAN WAY TO GET GOOD WAX.

I was always in the habit of boiling my wax in a bag, placed in a 2-gallon kettle made of galvanized iron; but one fine morning last spring my "biller busted" at the side. The more I tried to mend it, the more it leaked. I had to pour in cold water, and draw the fire. I did not want to pay six or seven dollars for another kettle. I let the matter lie until it could lie no longer. Then I wrote to you, to see if you could mail me one of your wax-extractors. The answer came, that it was not mailable. I lay awake at night, studying what I should do. Am I to be flanked—surrounded and beaten by a pusillanimous beeswax? Never! I jumped out of bed, into my clothes. An idea had struck me—hard! Mrs. Chaddock's plan was inadmissible. Mr. Porter's plan was destructive; Mrs. Harrison's plan was dirty and bothersome; Dr. Miller *just* missed the mark. We had a small sun extractor; but I went to work and made one 4 feet long by 24 wide on top. I lined it with bright tin, and put in a spout long enough to run through the wall of the honey-house. You see, I was preparing to extract honey as well as melt beeswax. That sun extractor, set on the south side of the honey-house, with pipe running inside of the house, was all that could be desired for melting small cakes of honey like mine. But, for wax it beats the world. Take Dr. Miller's large dripping-pan, with a hole "busted" in one end of it (I put a half-round spout in mine); grease the pan well, and lay a piece of old sacking in the bottom, just the size of the pan, except behind; let it come up far enough to catch hold of. Now raise your dripping-pan a little in the rear, and fill it up with wax. It doesn't make any difference how dirty it is. Now grease a big dishpan, and set under the spout of the dripping-pan. Put on your sash, and go about your business. In the evening all the nice yellow wax will be in your dishpan. In the morning fill up again, and so on until your dishpan is full. It will all be in one solid cake, for the wax melts alike, you see, in both pans. When you are done, the rag will readily pull out of the dripping-pan. Roll these rags up, tie them with a string, and put them in an old hive until you get for or five of them. You can then boil them. You will get a little cake of wax from them, which you can run through the dripping-pan process with the next lot. Now, here is no dirt, no watching, no boiling over; no bother or fussing, and *always* a clean, clear, yellow wax. I never could get two cakes of wax of one color before. All the wax is now nice and yellow. The dirt *does* not melt and run, consequently it

stays in the dripping-pan. There is nothing to clean up. Your dripping-pan is ready for the next lot, and is kept for that purpose alone. As for the rags, you would need to boil *them* out only once a year. If you are lazy, you can throw them away without losing much.

I see by Oct. 1st GLEANINGS, that friend Hart, of Florida, has got hold of the sun extractor for wax; but he, too, melts only the wax. The idea is, to get it in just the shape you want it for market, and the above plan does it all at one operation. Any plan to render wax that is thorough, complete, clean, and that will give a uniform bright color, must of necessity be very valuable to the average bee-keeper, and I am he.

Our loss of 20 stands, I should have said, was partly caused by moth. As we pay no attention to bees in this country, from the close of the honey until about the next February, any loss or death of a queen is sure to be followed by a loss of the colony. You folks think you know something about moth; but you don't. With you they are a nuisance; here, they are a besom of destruction.

We commenced on 95 hives; had 5 natural swarms, making an even hundred. After the season closed we made 52 three-frame nuclei. Here we can winter three frames, with a good queen, as well as nine. We now number 152 stands. None of these nuclei were made on the Doolittle plan. We did make one on that plan, but—well, you know its fate. J. P. ISRAEL.

San Dieguito, San Diego Co., Cal.

Friend I., I have for years been aware that a feeder, or some chunks of honey, or, if you choose, a dish of cappings, put into the upper story, at a time when honey is coming in from the fields, will have the effect of making the colony useless. I will repeat what I have given before, perhaps once or twice. When we first commenced extracting we thought to save the honey sticking to the cappings, by putting them on a honey board over a strong colony. The whole colony turned all its energies to fussing with those cappings, licking off the honey, and working the wax out into fantastic shapes. But while doing this they didn't increase an ounce in weight, while colonies right side by side were gathering 10 lbs. of clover honey a day. It would have been money in our pockets, a good many times over, to have dug a hole in the garden, and dumped the cappings into it, instead of putting them over the hive. New hands at the business often defeat themselves in just this way. They keep their bees fussing with feeders, or some trash that they want to save, when the bees might gather quite a crop of honey by going out into the fields. It may surprise some to know that bees will bring in more honey from the fields than they will take out of any kind of feeder you can fix. This fact upsets some of the talk about feeding bees sugar and glucose, to get comb honey.—In regard to the sun wax-extractor, I do not quite understand what you say about extracting honey as well as beeswax. And you speak of melting "small cakes of honey." What do you melt small cakes of honey for? Isn't it a fact, that the heat of the sun in your climate is much greater than it is here in the States, even in the summer? It seems to me astonishing, that the heat of

the sun alone, unaided, should melt beeswax. An arrangement of mirrors, or even some sheets of bright tin, would do it, of course; but in our experiments with cold frames in greenhouses we never yet have had any heat up to the melting-point of wax, that I remember. We see by the A B C book that wax melts at 145°. If the sun's rays are all utilized, and the space receiving them closely confined, no doubt we should get this degree, or more, during our warmest summer days. How many of the friends have used the sun wax-extractor in our latitude?

A REPORT FROM MRS. AXTELL.

HER VISIT TO MRS. HARRISON.

WE have gained much valuable information from GLEANINGS. The only trouble is, I can not keep them, as I find them too good to keep. I send them here and there, and then we find ourselves entirely without a bee-journal for reference, although we take three. Mr. Axtell and I are so glad that Ernest can take the place he is doing by way of help, both on notes on the apiary and children's corner. I think he will succeed in interesting the young folks, and I shall want to be young long enough to read them myself.

From about the 12th of Sept. to the 23d we had a wonderful honey-flow. We began to inquire where we could get sugar to feed up for winter, as many of our colonies were almost destitute; but in those few days many colonies that had not more than 10 lbs., increased to 40 or 50 lbs. of honey. We hope the bees will winter all right upon it, because it is so well sealed up. We have reduced the size of the hive to 4 and 5 combs spread apart, as some of our best bee-keepers have advised, and set the combs up one inch or more from bottom-board, and the hives to be wintered out of doors are packed on all 4 sides with dry chaff and on top, and we hope to escape the great loss in bees we sustained last winter. The combs are so solid with honey as to weigh from 6 to 13 lbs. I never saw so much brood and so much honey crowded into a brood-nest before.

We had several small colonies in August, too small to store comb honey, so we set upper stories over them and filled all with brood-combs, 48 combs, to be protected from the moth, combs left by dead colonies. First we partly covered the brood-nest, and then set in the combs. There was considerable honey in those combs, which caused brood-rearing, and I never saw such enormous colonies about Sept. 10, but scarcely any honey. We thought of dividing them into smaller colonies, but did not; but, how they *did* bring in the honey was astonishing. They had but little inclination to work in boxes; some of the stronger ones did, as we took away all those extra combs to get them to store in brood-nest for winter.

Last week Mr. Axtell and I made a visit to the home of Mrs. Lucinda Harrison. She is a lady of means, and I should think had no need of caring for bees; but she has a great heart, and does not live for self alone, but to do good, especially in caring for motherless children. Her husband was away from home upon one of their farms a few miles from Peoria. They have a young girl with them 9 years old, they have taken to bring up. She

is a very sweet, affectionate child. When asked to sing, she sang,—

"What makes the lamb love Mary so?"

The eager children cry;

"Oh! Mary loves the lamb, you know,"

The teacher did reply.

I thought that was the secret why Mrs. Harrison's lamb loved her so much—because Mrs. H. loved her lamb, for I never saw a more affectionate mother. I think she said she had 70 colonies of bees now. She lost quite a number last winter, and sold some in the spring. She is very determined to try to winter without so great a loss again. In her cellar she has been having a sub-earth ventilator put in. We were so pleased with it that Mr. Axtell, immediately on our return, began to arrange for one in our cellar, which begins in the bottom of the middle of the north part, and runs to the north of the house some 70 feet, and will take an 8 or 12 inch tile.

As Mrs. H. is acquainted with a good many of our prominent bee-keepers, and had visited some of them at their homes, it made a very enjoyable visit to talk with her. She mentioned a visit with Mrs. Mahala Chaddock, who lives in the middle of a beautiful large farm, surrounded with all the necessities of life; a visit with father Langstroth, for whom, when in his presence, she felt such a reverence; Mr. A. I. Root, such a meek man, whom all felt constrained to honor; Mr. Heddon, whose cases for box honey she had been trying this summer, were so neatly and well finished.

CLEANING WAX FROM TINWARE.

Noticing your suggestions in GLEANINGS, to heat tinware before rubbing off the beeswax, I would add, then pour on lye, and rinse around and wash off, and it will take off all that yellow tint, leaving them looking bright and new. If a box of what we should think was mostly propolis be poured into a boiler of hot water, the propolis will melt and sink, but considerable nice yellow beeswax will arise to the top, so that I always save all my scrapings, and much wax may be saved by boiling old bee-sheets covered with propolis, if one wants to be very saving, and has time.

In taking off our racks of honey it seemed almost impossible to get the bees all out; but the racks with the few remaining bees were put into the honey-house where many crawled out through a place made for them at the top of the window, and ran up the wire cloth; but others found the same way in again, but there were a good many formed into a cluster in the cone of the building. I told my husband I felt almost sure they had a queen, because they were building worker comb, which you know bees seldom do when they have no queen; so Mr. Axtell took a nail-keg and held it up close under the cluster, which would fill a two-quart measure, and quickly brushed them in, comb and all; there were but 3 small bits of comb, the size of the palm of my hand; but it had eggs in, showing that they had a queen. We put two combs of honey into the hive that I am certain had no eggs in, and poured the bees on to a white cloth, a small distance from the entrance to the hive, and let the bees crowd in. I caught and caged the queen, and gave to a queenless colony. I took the three bits of comb, with the eggs and a little honey in, and laid on top of the two combs that had no brood; the bees removed all the honey and eggs in a few days. I wished to unite them with a weak colony, and they had a nice cell built, and an egg in it; one oth-

er cell, but no egg. I think the bees carried that egg from that bit of comb, because it was but a few days after, that the bit of comb was laid on top, just about the same length of time that a weak colony would have built a queen-cell if eggs had been in the brood-combs. The bees were on the two combs I set in the side of the weak colony, with the least small place for the two colonies to crawl together. I think they did not all get together for three days, and I gave each colony a section of scrap honey. I can not see that they killed each other at all.

Mr. Axtell and I enjoy reading *Our Homes*, and *Myself and Neighbors*, very much, and we feel that we are always benefited by them. Ernest speaks of one of your colonies as appearing to have the "bee disease." I noticed two of ours troubled a little in that way this fall, spotting the alighting-board, and even on my hand, so I had some little fears about the consequences in the winter; but if we put them up to the best of our ability, we can only leave the result with God; and I am sure whatever the result may be, it will be all right.

Roseville, Ill.

MRS. L. C. AXTELL.

Mrs. A., just let your journals go as fast as people want them, and we will replace every one you give away; in fact, we will send you as many copies of each number as you think proper to distribute among your bee-friends and acquaintances. Of course, you would not want to give the same person a number each month, for then there would be no need of his subscribing. But we are always willing to furnish as many sample copies as our subscribers can make use of; and we will furnish any of our subscribers with any number of any particular issue, for that purpose.—We are very glad indeed to know of your yield of honey, even though it did come late in the season.—Now, Mrs. A., I want your husband to be sure to report how his sub-earth ventilator works. Let us know what size of tile he uses; and when it is below zero outside, please tell us the temperature of the air where it comes into the cellar. You do not say how deep the tile is to be put. Please mention that also.

G. S. BROWN'S BEE-FEEDER.

SOMETHING NOT EXACTLY NEW, BUT GOOD FOR ALL THAT.

IN regard to feeders, I have been bothered more or less with robbing. I have a feeder that you can put inside of the hive, and no robbing. Take a 2-inch plank and fit it in a frame; take a $1\frac{1}{4}$ -inch auger; bore the holes as close together as you can. Leave one in at each end, and bore within one-half inch of the bottom. Cut out about half way down, and you have a feeder that will not leak. I use sapling-pine plank. I do not plane the plank. Nail in the frame when made. I can make four in one hour by hand. Bees will not get drowned in them. I use a tunnel to pour the feed in. Pour in at one end until full. The bees will lie as snug up to the plank as they will with comb, and you can put the feeder in the center or outside the frames. I have made a good many for my neighbors, and they say that they are the thing to do

feeding. I have two swarms that I am going to feed all winter, as they need it. I winter in cellar.

Salisbury, Vermont.

G. S. BROWN.

I may explain to our readers, that the above is simply a piece of plank, as mentioned, cut so as to fit inside of an ordinary brood-frame. The auger-holes are bored from the top edge of the plank. After being bored and cut out as described, the plank is slipped into the frame, and nailed fast. Such a feeder will hold a quart or more; and as it occupies just the space of a good thick comb, it makes a compact way of giving the feed. The wood is as warm for the bees to cluster against as a comb of honey itself. Such or similar feeders have been in use before, and I really don't know why they have been dropped. We can furnish them for 25 cts. each, if wanted.

REPORT FROM I. R. GOOD.

FROM 7 TO 85 COLONIES.

THIS has been a good season here for bees. I left Tennessee June 18th, leaving my brother and his son, who is an experienced bee-keeper and queen-breeder, to take charge of my bees there. I arrived here June 20th, and found that I had but 7 colonies of bees left out of 65 last fall. I determined to run these for increase only, consequently I commenced dividing at once and kept it up all summer, dividing as fast as the bees would bear it. The result is, I have just finished packing for winter, 85 colonies of bees, all good and strong but about 8 or 10 rather weak ones. This was done without any feeding.

In preparing them for winter I have taken out several hundred pounds of honey that I have set away for spring feeding. The bees had but little comb to build, as I had nearly enough empty combs for the 85 colonies. There appeared to be a continual flow of honey all through the season—enough to keep the bees breeding, and keep them out of mischief. There was no time through the summer when robbers would bother while working with the bees.

The bees at no time this fall have killed off their drones as they generally do. We have had very nice and warm weather the last few days, and there were hundreds of drones flying. Is not this unusual for bees?

QUEEN-CELLS GOOD EATING.

This summer one of my near neighbors caught a runaway swarm of hybrid bees. He hived them, and they went to work with a will, and soon filled the hive with comb, and one case of sections. After the sections were nicely filled, the man took them off and gave them a case of empty sections; but a day or two after this he came to my house, requesting me to come and hive his bees, saying they had swarmed without saying any thing to him about it. I went to one of my colonies that had queen-cells about ready to hatch, and cut out two cells that were built close together, intending to put them in his hive in order to Italianize his bees. Before reaching his house his son met us to tell me that I need not come any further, because their bees had left; but I told the man I would go and look at the colony they came out of. When we got to the place I laid the queen-cells on the stand the hive stood

on, and proceeded to open the hive. In opening it I found the bees had absconded, leaving neither queen-cells nor bees behind, and the young bees would run out of the hive and drop on the ground in front of the hive as fast as they would hatch. After looking the hive through I looked for my queen-cells; but not seeing them I asked the man if he had picked them up.

"What," says he, "were those queen-cells? I picked them up and ate them, thinking it was honey."

His little son, who stood by, said, "Father, was it good meat?"

He said it was sweet. This was in the midst of basswood bloom.

My nearest neighbor, George Stuckman, who is one of your subscribers, purchased, on the 13th day of August, a swarm of bees that was the largest swarm I ever saw, and I think the largest I ever heard of. They weighed $13\frac{1}{2}$ lbs. I helped weigh them; and the funniest part of it was, this was the sixth swarm out of the colony they came out of.

Nappanee, Ind., Oct. 26, 1885.

I. R. GOOD.

Friend G., you know I told you some time ago that I didn't believe you would find as good a locality for honey in Tennessee as you have in Nappanee, Ind. The above corroborates my opinion. A swarm weighing $13\frac{1}{2}$ lbs. is a tremendous one, to say nothing about the six swarms from that colony, and as late as the 13th of August at that.—I have sometimes got brood in my mouth, when eating honey carelessly, and although I found it somewhat "sweet," as your neighbor did, it was almost too rich for my taste. If the cells you mention had queens nearly ready to hatch, I should have supposed he would have found the honey a little peculiar.—You know our good friend Langstroth says, in his book, he could increase from 10 to 100, by judicious feeding when it is needed; but you have done considerably better than that.

FROM 135 TO 210 COLONIES, AND 11,000 LBS. OF HONEY.

HOW SOON BASSWOOD, CLOVER, AND BUCKWHEAT, YIELD HONEY AFTER A RAIN; RED CLOVER AS A HONEY-PLANT.

ENCLOSED you will find my record of the daily yield of honey for 1885. In your remarks following my report for 1884, p. 692, you ask, "Did you keep a record so you can tell us if the temperature and moisture of the atmosphere alone produced these results, or is there a large flood of honey one day and but little the next, without any one being able to give satisfactory reasons why it is so?"

I was unable to answer your question then; but as I have this season kept a record of the weather in connection with the honey-record, I observe that white clover and buckwheat yield but little honey for several days after a hard rain, while basswood and red clover yield honey as soon as the rain ceases. In fact, some of the largest yields from the above were obtained the day following a hard rain-storm. They also gather honey very fast for a few hours preceding a very hard thunder-storm, when it is very hot and still.

As the record shows such a large amount from red clover, some may think that I am mistaken;

but I can say that I saw the bees *very thick* on red clover for two weeks, while I could find scarcely a bee on hundreds of acres of buckwheat in full bloom near my apiaries.

I commenced the season with about 135 colonies in three apiaries; obtained 11,000 lbs. of honey—5000 lbs. extracted, and 6000 lbs. in one-pound sections; increased to 210 colonies, in good condition to winter.

Summary: Total gain, white clover, $62\frac{1}{2}$ lbs.; basswood, 111 lbs.; red clover, 115 lbs. Total, $288\frac{1}{2}$ lbs.

There was also a small daily gain from buckwheat later, and also from white clover previous to June 24th; but I kept no record of it.

Mauston, Wis., Nov. 1, 1885.

FRANK McNAY.

Many thanks, friend M., for your very valuable report, and the facts you give us. Our older readers will remember that E. E. Hasty, some years ago, gave us figures showing pretty conclusively that the increased flow of honey was almost always an indication of coming rain, and that a rain could be foretold by the sudden increased yield of nectar, indicated by the scales holding a suspended hive.—We have long been aware, that a hard rain stops, for the time being, the yield of white-clover honey; but I have never noticed that this same rule didn't apply to red clover. We presume your great yield from red clover was made from the common, ordinary kind, although you did not say so. It seems to me to be a fact, that red clover may yield large quantities of honey occasionally, but that only occasionally,

What to Do,

—AND—

How to be Happy While Doing It.

CHAPTER I.

Whoso findeth me findeth life.—PROV. 8: 35.

DEAR FRIENDS, I am very well aware of the magnitude of the task before me; namely, to tell every one who is out of employment, what to do. But even this would not be so difficult if it were not for the latter part of the caption to my book. I might possibly tell every one of you who is wanting something to do, something that you might do. For instance, I might tell you to go and dig a ditch, and drain off that puddle of water that has stood before your door. Very likely you would agree with me, that it ought to be done, and that it would probably pay in the long run to do it. Still, only a few if any of you would be happy in such a task. You would say, "I beg pardon, Mr. Root; but I have not got down to digging ditches for a living just yet," and so you would drop my book, and cut my acquaintance.

Well, when I propose not only to find something for you to do, but something you will be *happy* in doing, I certainly have undertaken a tremendous task. I suppose you know we can sometimes get children to do disagreeable work, and enjoy it too, by creating an interest in the work—sometimes by indirect methods. When a boy, my task was to saw and split the wood for the kitchen stove; and, as with the average boy, my good mother was almost always out of wood, especially when baking-day came. The work was so disagreeable to me, and I had so little heart in it, that I always got just enough for present needs. Sometimes, after she gave me a motherly reproof, I would start out with great energy and big resolutions; but in a very little while I would say to myself, "I declare, I must go and see to my chickens. What I have, will last fifteen minutes any way, and I am sure I will come

back before she can have time to want it." Well, reader, how do you suppose it turned out? No different from what it did almost every day. The wood was all gone; my mother scraped up the chips, and tried crowding great chunks into the stove-door, to get along, while somebody went after "that good-for-nothing boy." I was reminded of my remissness, perhaps, by hearing some of my brothers or sisters shout over the gate of my poultry-yard, "Amos, mother's clear out of wood again, and you are to come this very minute and get her a good lot of it." I had become so interested in studying my chickens, that I entirely forgot mother and the wood, and I fairly jumped in my shoes when reminded in this peremptory way. I went back, guilty and ashamed, and almost afraid to look my good mother in the eye; but, bless your heart! *she* knew how it was, and she did not look cross, nor did she scold. She understood her boy better than anybody else, and had no lack of charity and love for him, even though he didn't keep all his promises very well.

Well, shall I tell you what it was that all of a sudden made me love to saw and split wood, and even made me petition my father to draw another load, that I might cut it up? Yes, that something stayed by me until I worked with such energy that the sweat fairly ran down my boyish face; and I so loved to saw and split wood that I really disliked to stop long enough to go and get my dinner with father and mother and the other six children. What was it? Why, it was a new-formed purpose; and that new-formed purpose came to me one hot, sultry, summer afternoon. It was simply this: I got to thinking that I should like to build

a monument, and I wanted the monument away up high—higher than the one I made of snow and ice the winter before. The problem was, to get the building material. I couldn't buy lumber; stone was plentiful, but they were too heavy for me to lift, and I couldn't cut and put them together with mortar. Nothing presented itself better than stovewood. I well knew, without asking, that father and mother hadn't a bit of objection to my cutting up lots of stovewood ahead, and piling it up so the sun and wind would dry it nicely for the kitchen stove. At it I went, and up went the monument. Of course, the six children were anxious to know what new hobby that brother had got into his head now—one that even made him neglect his chickens somewhat. Of course, the only way to preserve my monument intact was to keep wood enough in a pile by the gate; and I was greatly tried sometimes, because some of my older sisters pulled wood out of my monument, instead of taking from this little pile. When I remonstrated, with tears in my eyes, they couldn't see that it made much difference where they got the wood. Mother saw the difference, though, and I presume she would have scraped up chips, and burned old chunks as before, rather than to have laid a finger on the structure that I had builded with so much boyish pride and enthusiasm. I wonder if the mothers who read these lines realize what a hold they may have on these boyish minds—a hold that they may keep through life, even when those boys are great strong men. Had it not been for the kind Christian counsel of this good mother, who knew me through and through, as no other human being did, I might not have been writing here to-day, with this beautiful little text at the head of my chapter.

The above little sketch illustrates what a difference it makes with the one who has work before him, whether he has a purpose and an end in view, or is simply working mechanically, without any purpose or end. Now, before I start out to tell you what to do, I want to try to awaken a purpose and an object in your hearts. Having a family on your hands to support, or being in need of the wherewith to purchase your daily bread, is an inspiring motive, or, at least, it ought to be such, I very well know; but, dear friends, I think there is a higher and a better one still, and I want you to start out with a plan for building a monument that shall not only go on through this life, but through the life to come; and I

want you to take into partnership with you in your undertaking, the great God of the universe. Whatever we do, we want to do it out of love to him. I want you to love his sunshine as I have been loving it for several months past, because it is *his* sunshine. I want you to love the gentle rain and the dews, because they are gifts he sends us daily. I want you to learn to love old Mother Earth, because it is his gift to man; and I want you to love the dumb animals about you, because they are his creatures. Furthermore, I want to show you how to appreciate these things so that you will love to make use of them for his sake. We want to learn to love the sunshine so much that we shall feel guilty if we lose even a little bit of it. We want to get up early in the morning, to enjoy the first glimpse of it. Then we want to be ready to go to bed about as soon as the last glimpse of it disappears. Even in the longest summer days, we want to be able to economize all the sunshine there is; and in the same way we would economize, as far as we can, all the rain and dew. We want to use these gifts as a faithful steward would use the money and property put into his hands. Do you begin to suspect that I mean to have you all become gardeners? Well, in one sense that is exactly what I have had in mind—at least, this far. No matter what your calling in life may be; no matter how you are situated, I feel sure it will add to your happiness to learn how to make things grow, with these aids God has given us. And even should it transpire that you may not have an opportunity at present of seeing things grow at all, I expect to give you general rules that will be great aids in making any business in life a success. One who can grow plants, and make them do his bidding, is prepared, to a certain extent, to make any other kind of business do his bidding.

I do not know how you are situated, of course; but my talk is principally directed to those who have leisure time on their hands; who have their evenings unemployed, or who have leisure during the winter months of the year. If you have unoccupied time during the usual growing season for plants, all the better. Neither do I know whether you are situated where frost and snow is the rule for nearly half of the year, or whether you are like the friends I met in New Orleans last March, who know nothing of any frost, sufficient to make it needful to have any kind of a cellar. Now, although my talks will be principally directed to those

who live as I do, where we have, on an average, from three to four months of winter, I expect these talks to be applicable, also, to those where winter is almost unknown. When I was a small boy, and was helping father raise a crop of potatoes, he remarked, that, if the weather were favorable, we should probably get a hundred bushels.

"Well, pa," said I, "suppose the weather is *not* favorable, how many bushels shall we probably get then?"

He replied, that we might not get over 25 bushels; but he added, in an encouraging way, "If the weather is favorable, it will be so for other people also, and the crop of potatoes raised will be so large they will likely bring only about 25 cents a bushel, giving us \$25.00 for the crop. If the weather is not favorable, other people will have a small crop as well as we, and the price may be a dollar a bushel; and in *that* case we should get \$25.00 for our crop. So you see it would not make any difference, after all. Our business is to do the best we can."

Now, I am going to add what father did not add then: That the expert farmer or gardener nowadays succeeds in getting a large crop, even if the season is unfavorable; and he may, if he is up to the highest recent attainments, get the 100 bushels of potatoes, and get the \$1.00 per bushel also; and that is what we are going to work for. In fact, that is what this book is intended to help you to do; and the principle is to be carried out all the same, whether you raise bees, chickens, strawberries, or potatoes. Take whatever God sends you in the shape of weather or opportunities, and make the best of them. Endeavor to see his loving hand through it all. If you are away down south, you can get bountiful crops with comparatively little exertion; while if you are up

north you will have to fight frosts and winter; but you will get higher prices on this very account. Sometimes farmers and gardeners get blue and discouraged because it rains all the while; at other times they get blue and discouraged because it does not rain at all. Now, let us shape our work so we shall have something to be thankful for. Let us make these forces of nature our friends, instead of our enemies. To illustrate what I mean: Several years ago I was greatly annoyed by the high winds blowing the bees down while the fruit-trees were in bloom, and I kept wishing we could have a day when the wind didn't blow. I finally told my wife that I was going to buy a wind-mill to make bee-hives, that I might be enabled to use this annoying and troublesome wind as a *servant*, instead of having it an *enemy*. At the same time I built a high fence around the apiary, and battened all the cracks, so that I had a small spot of ground that was tolerably tranquil, no matter how windy it was in other situations. Such wind-breaks pay all they cost, without any question, not only in bee culture, but in gardening and fruit-raising. Well, after I got my wind-mill all up, I wanted the wind; and I was so anxious to have it blow that I several times got up in the night to do my grinding and sawing. Thus you see I was fixed all right when the wind *didn't* blow, but I was fixed better still if it *did* blow. Brother Terry brings out the same idea in his potato-book. If a shower came up, and interfered with curing his clover, he consoled himself by thinking that his potatoes received more benefit than the clover received damage, and at the same time he did all in his power to protect his clover.

CHAPTER II.

Prepare thy work without, and make it fit for thyself in the field; and afterwards build thy house.—PROV. 24:27.

Our good old friend Horace Greeley used to advise the young men to "go west," as you may remember. I presume his idea was, that by going west they would find broad fields of fertile soil, where the results of their energies would bring good pay, and furnish comfortable homes for all. If you want to be a large farmer, no doubt the above advice still holds good. But my field of labor would be to commence at home, where you are. I have known a good many

young married people to go west, and after awhile come back to the very spot they left, poorer in purse, even if they were richer in experience. Now, if that money and time had been expended on a little piece of ground at home, it would have been far better. Horace Greeley had in mind broad fields. I would advise developing a few acres, or even one acre or less. From Peter Henderson's "Gardening for Profit," we extract the following in regard to the cultivation of

small patches of ground. It forcibly illustrates the point under consideration :

The passenger in the horse-cars going from Sixtieth street to Harlem, on New-York Island, any day from June to October, may see little patches of vegetation of different shades of green, ranged in uniform and regular lines. These are the "salad patches," cultivated mainly by German market-gardeners; they range from two acres down to a quarter of an acre in area. It seems a wonder that the cultivation of such a small plot of earth should give an able-bodied man a living; but a living it does give, in nearly all cases, and some have quite a respectable surplus for a "rainy day."

And now read the following :

Four crops of lettuce are usually taken from June to October, or nearly a crop each month. The plants are set about a foot apart each way, and will average one cent per head, so that the four crops give a return of nearly \$2,000 per acre. This seems like an immense return for an acre; but though the net profits are respectable, there are some serious disadvantages attending the cultivation. Few or none of these men are owners of the land, nor in hardly any instance have they a lease. They are tenants at will, and pay a yearly rental of, in some instances, \$250 per acre. Many of your country readers may think that an extra cipher has been added to the amount, but they must recollect that the value of some of these "salad patches," as they are called, is \$8000 per city lot, or over \$100,000 per acre, so that the paltry rental of \$250 per acre hardly pays the *interest* of the amount of taxes.

But, you may urge that these enormous figures were obtained in consequence of the proximity to the great market of the city of New York. Well, there is something in this; but there is something on the other side too. Last winter a good many barrels of lettuce were sent to our town by express, from one of our large cities. It retailed to our Medina people (and we are a town of less than 2000 inhabitants) at 25 cents or more a pound. When the trade commenced I started some lettuce in our greenhouse, and succeeded in getting heads that weighed a pound apiece, on an average. Now, in place of putting the plants at one cent per head as Peter Henderson has done, say 25 cents per head. What sort of figures per acre have you then? or what sort of figures would you get for the product of a little greenhouse, or even a few boxes of plants started in the window, and planted outdoors as soon as the weather would permit? The heads we raised were nicer and finer than any that I ever saw in the cities, or that came from the cities. But I hadn't the heart to ask over five cents apiece for them.

Now, I do not mean to advise everybody in the country, town, or city, to go to raising lettuce for a living. I have chosen lettuce only for an illustration, and I have, during the past year, demonstrated to my complete satisfaction that fine products of this kind will be quickly taken in almost any community, if the goods are properly brought before the people. The question may arise, "Is it well to encourage people in paying out their money for things of this kind that they would be just as well off without?" If you are going to seek first the kingdom of God and his righteousness, we do not want to go into any kind of business unless we can consistently and with a whole heart, ask his blessing upon it. I was at one time tempted to think that five or ten cents for a head of lettuce, or the same money for a stalk of celery, was an extravagance that perhaps ought not to be encouraged. Chemists tell us that a watermelon is 90 or 95 per cent water, or something of that sort. In that case, is it not sheer folly to pay 25 or 50 cents for a watermelon? A head of lettuce is, quite likely, 90 per cent water, or at least a large part of it, and nothing more. And so we might say of almost all kinds of garden products. They will do well enough for rich folks, where they have more money than they know what to do with. But, is it a kind of traffic that a Christian ought to engage in? My friends, I believe it is just exactly the kind of traffic that a Christian ought to engage in. Physicians have united, almost to a man, in pronouncing strawberries worth all they cost, on account of their health-giving qualities. A good many say the same in regard to garden-sauce of various kinds. Celery, for instance, has been recommended for years past; and after having made a careful test of the virtues of the plant, I think I am not mistaken.

During the fore part of this present season, my friends as well as myself were somewhat alarmed by a nervous attack that rendered it quite difficult for me to work in the office, reading letters, directing business, etc. A physician of considerable standing advised me to give up fruits and vegetables, and subsist principally on lean meat. He specially directed that I was to eat no vegetables during the latter part of the day. I began making careful experiments with many articles of diet. He was right in condemning certain fruits and vegetables; but I have proved, over and over again, that I could eat celery, right fresh from the garden, in great quantities, without any bad result.

I would go out after supper, and, after working among the plants, dig the crisp roots, and eat them down with as much relish, and with as little fear of consequences, as our Jersey cow would eat cabbage-leaves. I steadily improved, and, by working out-doors at the same time, I am now feeling so well that I read letters and dictate this book, hour after hour, without even any slight symptoms of the old dizzy feeling. My digestive apparatus is about perfect. I have tried crisp fresh lettuce, and it seems to answer much the same purpose; but I find I must have open-air exercise.

Now, dear friend, if you are ailing in *any* way, I feel strongly convinced that some open-air exercise, with fresh fruit and vegetables to eat, will help you.

Let me make another extract right here from Henderson's new book, "Gardening for Pleasure:"

About a dozen years ago I had the pleasure of making the acquaintance of a gentleman whose duties compelled him to be at his desk in a close office in the city of New York, from 9 o'clock A. M. to 4 P. M. Being naturally of a weak constitution, his sedentary life soon made him the victim of dyspepsia to such a degree that he felt that he must soon resign his situation. He was then a man of forty, entirely ignorant of any thing pertaining to country life, and it was with great misgivings and reluctance that, by the advice of his physician, he changed his home from a closely built part of New York to a cottage in the then country-like suburb of Bergen Heights, N. J. His means enabled him to purchase a modest cottage built on a lot 50 by 150 feet; he did not want the land, he said, but the cottage was such as he fancied, and the ground had to go with it. It was about this time that I formed his acquaintance, through some business transaction, and he asked my professional advice as to what he could do with his land, which he had already begun to consider somewhat of an incumbrance. I replied to him that, if I was not greatly mistaken, in his little plot of ground lay a cure for all his bodily ills, and that besides it could add to the comforts if not the luxuries of his table if he would only work it. "I work it!" he exclaimed. "You don't suppose that these hands could dig or delve," holding up his thin bloodless fingers; "and if they could, I know nothing about gardening." I told him I thought neither objection insurmountable if he should once begin.

The result of our conversation was, that he resolved to try, and try he did to a purpose. Our interview was in March, and before the end of April he had his lot all nicely dug over, the labor being done by his own hands during an hour and a half each morning. His custom was to get up at six o'clock and work at his garden until half-past seven.

This gave him ample time to dress, get breakfast, and be at his desk in the city by nine. The labor of merely digging was (to him) heavy and rather monotonous, but he stuck to it bravely, and when he again presented himself before me for plants and seeds and information as to what to do with them, it was with some pride that I saw my prescription had worked so well, for my friend then looked more like a farmer than a pallid clerk.

During his first season, of course, he made some blunders and some failures, but his interest in the work increased year by year. His family was supplied with an abundance of all the fresh vegetables and fruits his limited space could admit of being grown—a supply that it would have taken at least \$150 to purchase at retail, and stale at that. But the benefit derived from the cultivation of this cottage garden was health—strong, rugged health—that for the six years he was my neighbor, never once failed him.

I know this case is an extremely exceptional one, for I never knew another man who so resolutely worked himself into health. There are hundreds of business men, book-keepers, salesmen, clerks, and the like who live in the suburbs of all great cities, many of whom can ill afford to pay for the keeping of the plots surrounding their cottages, but who think they can far less afford to do the work themselves. As a consequence, in nine cases out of ten, the rear, at least, of their suburban plots is a wilderness of weeds. But this is not the least of the evils; the owner has a certain amount of muscular force, and this, be it more or less, being unused, its possessor pays the penalty of his laziness in dyspepsia, and a host of other ills. The proofs are apparent everywhere, that garden operations are conducive to health and longevity. The work is not unduly laborious, and when fairly entered into has a never-failing interest. The growing and the watching of the great variety of plants gives a healthy tone to the mind, while the physical labor demanded by cultivation takes care of the body.

Now, then, as we have disposed of all objections that might arise from a moral view of the matter, let us consider it in a pecuniary point of view. Will you be likely to get your money back? Well, I want to say right squarely, here, I do not want to take the responsibility in regard to this part of the business. If you have a natural liking for plants, dirt, sunshine, and rain, and selling things to your neighbors after you have raised them, I do not believe there will be any probability of failure. If you go at the business as I went at the wood to make a monument, you will succeed; and if you go at it because you love God and your fellow-man, you will *surely* succeed; for God himself has promised you success. Seek first the kingdom of God, and his righteousness, and he will add all things needful.

CHAPTER III.

And God said, Let there be light; and there was light.—GEN. 1:3.

If you are going to grow plants for winter, when they will bring high prices, they must be protected against the weather. Heat must be secured. It is true, that heat and light come closely together; and where we get them from the sun, we get them both at once; but for all that, we will take up the subject of heat first. Let us put it in large letters—

HEAT.

There are several means of securing heat for our operations. First, we have heat from the sun; then we have heat from old Mother Earth, and artificial heat by burning coal and wood. Artificial heat may be still further subdivided into heat from hot-air flues, heat from hot-water pipes, and heat from steam. Then there is another kind of artificial heat from the decomposition of certain substances without combustion, such as heat from fermenting manure, although the last is now seldom used, I believe. Let us take up first,—

HEAT FROM THE SUN.

There has always been something wonderfully fascinating to me about the heat of the sun. I hardly need tell you that scientists decide that the heat from the sun is the source of all force. The health-giving properties of the sun's rays have been for ages mentioned and made use of. In visiting the great sanitarium at Battle Creek, Mich., I was very much interested in visiting some rooms clear up in the attic, where they put diseased patients, close up to the glass sash placed in the roof, much like the roof of a greenhouse. They lie here on their beds, partially uncovered, where they can receive the benefit of the sun's rays. Neither plants nor animals can amount to very much without the direct benefit of the sun. In our operations we want all the sun we can get. If we can not do any better, let us use our windows, instead of having the warmth of the sun shut out by curtains and other artificial devices. The windows of any room where people live will do to commence plant-raising on a small scale. When you get all the windows occupied, and have succeeded in utilizing every available inch of sunshine, you will find a way to get more, I am sure. "Where there is a will, there is a way."

Probably your next step will be a few frames of sash, such as are used for green-houses. We shall have more to say in regard to these further on. These frames of sash that are so useful in raising early vegetables are just what we need for raising early chickens, and for getting eggs in the winter time. Of course, it does not do to keep poultry too warm, any more than it answers to keep plants too warm; but we propose to start out intelligently, and avoid *baking* or *roasting* any thing, plant or animal. *Too much* heat can be utilized, just as well as you can make use of a surplus of any thing else. When we have secured all the sunshine we can, by the way of some sash, or a little greenhouse, then we want to husband it by cutting off the cold winds, which will quickly rob us of our acquisition, if we do not take proper precautions. A fence for a wind-break, such as I spoke of a little while back, is what we want. A great many times you can make use of natural wind-breaks. In a town or city you can often choose a location where the prevailing winds are cut off from the north and west. We want to cut off the wind, but let in the sun, so that our wind-break on the east and west must not be too high, or we shall lose as well as gain. Where you have ample wind-breaks, lettuce and a good many other hardy vegetables may be raised by proper precautions, without any sash at all. A shed, closed on three sides and open at the south, such as farmers often use for their stock, is an excellent thing, only we must look out about the covering overhead, or it will take off the light so as to make the plants grow spindling.

One cold wintry day I happened to go off into a piece of dense woods, where a neighbor was chopping wood. The trees were so high, and the woods were so dense, that in the little spot of clearing where he was at work there was no wind at all. The sap was running, and the bees were buzzing about. I thought the weather had changed, and wondered that it had so suddenly become so much warmer. After I got out of the woods again, however, I found that the weather was not warmer at all. It was simply the effect of those great forest-trees in breaking the force of the wind. Ever since

that I have been wishing I could have an apiary located in just such a spot. In hilly and mountainous countries they frequently choose such sheltered spots for early gardens. May be you know of such a place. If so, accept it as a gift from God, and go to work and be happy.

Some years ago I had a little greenhouse built partly under ground, for some experiments for making bees rear brood in the winter time. The east, west, and north walls, and the north half of the roof, were protected by layers of dry earth, nearly a foot in thickness. Over this dry earth a shingle roof was placed, to keep the building from getting damp. The whole south side, and the south slope of the roof, was of glass. The sun alone warmed up this structure so that I could work there in comfort with my coat off, while it was freezing weather outside. Ever since that experiment I have wondered why people do not have rooms in their dwellings, warmed by the heat of the sun, thus saving quite a bill for fuel, and dispensing with the care of stoves, during at least a great part of every winter. What a grand place such a room would make for a playroom for the children!

HEAT FROM THE EARTH.

Greenhouses are usually built partly under ground, in order to secure the benefit of the heat from the earth. In Mammoth Cave we have an even temperature of about 55°. This temperature will answer very well for raising lettuce and radishes, providing you can get light, without frost. The difficulty, however, comes in here; you must have light on all sides of the plants, and they must be tolerably near to the glass, or they will grow spindling and one-sided. If we were sure the sun would shine every day all winter, we could make a greenhouse (or cold frame, rather) that would answer nicely, by simply utilizing the heat from the earth and the heat from the sun. It happens, however, that the sun does not shine more than perhaps one day in four, on an average, during the winter months; and although we have the walls never so well protected, if we happen to have zero weather during cloudy days, the frost will come through the glass sash prepared to let in the sun's rays, however tight the joints may be. We then should have our garden all frozen up—at least, that portion of it that lies very near to the glass, without some kind of heat to reinforce the heat from the earth. Two thicknesses of glass have been suggested and tried, with an air-space between the two sashes; but as

quite a portion of the heat of the sun is lost in passing through even *one* thickness of window glass, we lose considerably more where it passes through *two* thicknesses. A still further objection is, that the outer glass would be covered with frost, which might remain days or weeks, thus cutting off light as well as heat; whereas, with only one thickness of glass, the heat of the interior of the house quickly melts off the icy covering, with the assistance of the sun from the outside. There is another way of managing without any artificial heat, so that hardy plants will not be killed; and this is, to have a good-sized cellar adjoining the greenhouse, so that a free communication of air can be easily opened between the cellar and the greenhouse. The large body of air in the cellar will be considerably cooled off during a cold night; but in its turn it will warm up the body of air in the greenhouse, so that the whole will keep above a freezing temperature. As soon as the sun comes up in the morning, however, this communication with the cellar must be cut off, or the sun will have but little effect on so large a body of air.* All things considered, however, a little artificial heat during the severest portion of winter is thought to be the simplest and easiest; but as it is a very easy matter to injure the plants by too much heat by a little carelessness, an arrangement of pipes for carrying hot water seems to be by far the most practicable method. Steam has recently been made to answer very well; but, like the heat of the stove, or a flue, since it is so liable to get things too hot, the hot water seems to be safer.

We would make the greenhouse as much under ground as we possibly could, and still get light enough so that the plants should not grow "long-legged" nor one-sided. The sun's rays coming through the glass would warm up the walls and floor during the day, and these same walls and floor would hold heat enough to keep the plants from suffering until the sun's rays could cause a reinforcement the next day; and many plants would grow better this way than with the aid of artificial heat. Such structures can be used in places far enough south so that the temperature is never quite down to zero; and they are also used in our own latitude after the severer portion of winter is past, say during March and April. They are called "cold frames." They are also used for wintering over such hardy plants as lettuce,

* An open tank or cistern of water will answer the same purpose as a body of air, to a certain extent.

cabbage, etc., by lifting the sash so as to give air when the weather permits, and covering the plants when the weather is severely cold; for it is well known, that the class of plants mentioned will stand even 15 or 20° below zero (covered with sash) if they are properly cared for, or gradually accustomed to the cold. Such structures are also quite valuable for poultry. I believe, however, the best authorities on poultry rather discourage the use of artificial heat.

In connection with heat from the earth, it may be well to speak of what has been called "sub-earth ventilation." Of course, our greenhouses, poultry-houses, or buildings for any other purpose, kept warm during the winter time, must have constant accessions of fresh air. Well, *outdoor* air is often at a low temperature, sometimes below zero; and this air must be warmed up by some means, else it will lower the temperature of our inclosure. If we warm it up by means of hot-water pipes or steam-pipes, it takes quite an amount of fuel, besides the labor of keeping fires. Well, instead of having a large cellar to warm our body of surplus air to the proper temperature, we may have a pipe, or series of pipes, running some distance under ground, below the point where the frost reaches; and the cold air, taken, say, from out in the fields, at a *zero* temperature, becomes warmed up to 55°, the natural temperature of the earth, in its passage through these pipes, providing the pipes are not too large in diameter, and are sufficiently long. Usually some arrangement has to be made to make the air travel in the right direction; and sometimes a sort of chimney a few feet high is put up at the inlet, and this chimney is surmounted by a sort of funnel, or hood, which is kept facing the wind by means of a vane. This starts a current in the pipe; and the cellar or greenhouse where this stream of air at 55° empties has an outlet near the roof, to let the warm air escape. I may say, however, that, in practice, during *zero* weather the air usually escapes fast enough, without any provision for an outlet. The size and length of these sub-earth pipes depend a good deal on circumstances. Some authorities recommend that they be laid at least eight feet under ground, and run a distance of 200 feet; but as such an arrangement would be quite expensive, many of our bee-

friends have had very good results by laying a line of common underdraining tile, say three feet deep, and only fifty or sixty feet in length, the tile to be three or four inches in diameter. While this might not raise the temperature of the air during zero weather to fully 55°, it would probably raise it considerably above the freezing-point. Some experiments are needed in this matter.

In passing out and in Mammoth Cave during a frosty, wintry night, we began to find that the stream of incoming air felt chilly when we were perhaps an eighth of a mile from the mouth of the cave. In this case, however, the stream of air was very large, and at the door of the cave it blew almost a gale. Sending a stream of cold air down into a well by means of a pipe, and then collecting it at the mouth by another pipe, would also answer to remove the frost. But if the stream of air passing down is very large, it might have the effect of freezing the water in the well.

Now, where there are large natural springs coming out of the hillside, we may, by a very simple arrangement, bring large quantities of heat from the earth, and utilize it by conducting the spring water back and forth in open pipes until it has parted with the heat it contains, until its temperature of 55° is reduced nearly to the freezing-point. By having these channels protected by a sash we can combine the heat of the earth and the heat of the sun so as to make an excellent cold frame for hardy plants, without the use of artificial heat. The spring water may be passed back and forth under the beds. The heat it gives off will operate in the same way as the heat from hot-water pipes; only we shall never be able to get above 55° without the aid of the sun. This spring water would be just the thing for watering the plants, and such an arrangement can be made very pleasing to the eye, as well as profitable to the pocket. A little fountain, or several of them, if made so as to throw a small spray, would induce the water to part with its heat still more rapidly than the open channels. One of our most successful bee-men in the State of Michigan has a spring in the cellar, or cave, where he winters his bees. The water from this spring, flowing through this room, is found a check to keep the temperature from running too low.

To be continued Dec. 15.

He that is faithful in that which is least, is faithful also in much.—LUKE 16: 10.

MYSELF AND MY NEIGHBORS.

For where two or three are gathered together in my name, there am I in the midst of them.—MATT. 18: 20.

I SUPPOSE, friends, that even the juveniles have heard this little text just above what I am writing, over and over again, especially if they ever went to a prayer-meeting where only a few were present. The above text, or the substance of it, would come somewhere in the first prayer. Well, now, it is a grand little text; but it is the five verses that go before it that I shall have to do with now. The first of these five verses reads like this:

Moreover if thy brother shall trespass against thee, go and tell him his fault between thee and him alone; if he shall hear thee thou hast gained thy brother.

Perhaps you would like to know what brought this to mind. Well, it was like this: One of my neighbors, whom I will call Mr. A, came to me, saying he could not get along with neighbor B, any way possible; that it was no use trying any more.

"My dear friend," said I, "you know you had trouble with neighbor C, not very long ago, and thought you could not get along with him possibly. Now, whenever I get to feeling that way (and I often do, I own up). I always begin to feel a little uneasy for fear the trouble is with *myself* and not with my neighbors."

"Mr. Root, I have thought of that, and I suppose I am ugly enough myself; but I have got all over my trouble with neighbor C, and I can get along with almost anybody now, except neighbor B."

"But, my dear friend, do you remember that you and neighbor B are both members of the same church—both followers of Christ—or, at least, profess to be?"

"Yes, I know all that; but I have tried and tried, and I don't believe it is of any use to try any more."

"Well, if *that* is the case, there is a plain remedy in the Bible. Have you tried that plan?"

"No, I have not tried that plan. The fact is, I am too ugly myself. I know what is the best way, and the right way; but it is not in me. I have not the gift of saying what ought to be said, in the way in which I know a Christian ought to do these things."

"I thought a minute, and finally said, 'Would you like that I should speak to neighbor B about these matters?'"

"Yes, Mr. Root, I really wish you would. There is not any use for me to talk any more."

"Come to think of it," said I, "I rather think the better way would be for me to talk with you both together."

This plan did not suit him so well, but he finally assented, and conscience commenced her work, as I knew pretty well she would; for I knew that this neighbor, whom I have called A, for illustration, was trying, and trying pretty hard, for one of his temperament, to follow Christ. He has his own notions, and very strong likes and dislikes, and quite a temper to keep the upper hand of, with all the rest. In the course of an hour or two I was not surprised to see him come around with a pleasanter look upon his face; and

with eyes somewhat downcast, he said, in a kindly tone of voice:

"Mr. Root, if you will be so kind, I guess you need not do anything about what we were talking of. May be I can do a little better, and I am going to try hard."

I wonder how many there are whose hearts will be touched by this little story of everyday life. How many are there of you, my friends, who know what you ought to do, and who have felt in your inmost heart that you hadn't the right spirit to do it? Those who are older in the Christian work would perhaps have said, "I have not grace enough." What, then, is grace? Is it not the influences of God's Holy Spirit—meekness, love, charity, long suffering, and all these other things—the fruits of the Spirit, if you choose? Oh how often I have been compelled to pray, almost in real anguish of heart, "Help me, dear Savior, and give me that spirit of gentleness, kindness, meekness, and love!"

I told you there were five verses that I had in mind; but I have as yet said nothing of more than one of them. The second verse says, that if this spirit of meekness and love does not answer the purpose, we shall take some other brother, or a couple of them, with us; and here is this wonderful plan of arbitration mapped out—the plan that has of late been used to prevent fierce wars between great nations. What a grand and what a wonderful truth is there in these simple little words of Christ the Savior! My experience has been, however, that among neighbors (and it is of neighbors we are talking) there is seldom any need of any third party at all. If you do your part, your neighbor will be almost sure to do his part. It takes two to make a quarrel; and where even one of the two shows a Christian-like spirit (and this does not mean that you are by any means to allow yourself to be run over, for a Christian must be brave as well as kind), my experience has been that the quarrel ends. I suspect that the trouble between these two neighbors, A and B, was, that Satan's spirit, instead of Christ's, had got between them. They were both at fault, no doubt, and I fear both had forgotten the teachings of the Bible, especially the five verses I have been speaking of.

The third of my five verses directs that the complaint shall be brought before the church, and that the church shall deal with both parties, if need be. If either one refuses to submit to the church, of course he must reject Christ and Christ's teachings; and in that case there would be little hope for him. He must be treated as a heathen, or one who rejects Christ, and one who rejects Christianity.

The fourth verse tells us that these things that are settled here on earth are settled for all time to come; that these little acts and quarrels go on to eternity, and even reach as far as heaven and hell.

The last of the verses considers the attitude of, and what may be accomplished by, two Christians working in harmony and brotherly love. If even two of us agree in any petition to our heavenly Father, Christ says that our Father in heaven will grant it.

Of course, we are to understand that this verse refers to two brothers in Christ. So greatly is God pleased to see us doing our work in brotherly love, and with Christ's spirit uniting us, that he has promised what we ask in his name. And then follows the little text that I started out with. Where even two or three of us are gathered together in the name of Christ, there will he be in the midst of us. And, dear friends, is not this little verse at the root and foundation of the church of God? Is it not the germ and seed from which any church must spring up, with Christ as a center? Let us read this little text together again; and as we read it, let us see if it will apply to *ourselves* and our *neighbors*.

For where two or three are gathered together in my name, there am I in the midst of them.

HOW A BEE CLINGS TO GLASS.

A TALK TO THE JUVENILES; ALSO SOMETHING FROM MR. LANGSTROTH.

AS I promised, I will now give the juveniles a talk on a bee's foot, and what it can do. If you will give me your attention for a little while I will try to make it clear to you how a bee clings to a piece of glass, and doesn't fall. Did you ever think how a fly can walk up a window-pane, and not slip?

Below is a drawing of a bee's foot, exactly as it appeared in my microscope. It is 40 times as long and 40 times as wide as the natural foot. D, D, are the two notched claws which the bee uses in clinging to wood and other substances which the bee can stick his foot into. Did you ever have a bee plant his little feet right into your flesh when he was getting a good hold so as to sting? These little claws are what hurt, and are almost as hard as your jack-knife. They do not always hold this position as seen in the picture, but they can close up like your thumb and finger, or can turn themselves clear around like the letter Y.

"How does the bee cling to a piece of glass?" I suspect you are beginning to ask. Just listen. There is a little film as at C, that looks a little like the head of a hatchet, or, perhaps, more like a fan. B is a pair of arms that keep this little disk, or fan, spread out on the piece of glass. A is a little muscle that looks like a potato-masher. The little end is fastened to the little fan-like film, and the other connects the end of the foot between the claws.

A BEE'S FOOT.

Perhaps this is a little hard for you to understand. If you will wait a moment I will tell you how to make something just like this little arrangement upon a bee's foot. Did you ever notice, when you were washing your hands in soap and water, how your hands will cling together by the force of suc-

tion? You must rub your hands closely together, and then, drawing them gently apart, you will notice how they adhere. If your little baby-brother were to wet his little fat chubby hand and press it flatly upon a pane of glass, then by drawing up his knuckles his hand would probably cling to the glass, providing you could get him to do it rightly.

An older person's hand would not do, as it is not flexible enough. One more illustration, and I will return to the bee's foot.

Procure a circular piece of leather, about two inches across (get your papa to help you), and through the center pass a string, tying the end in a knot. Now draw the knot close to the leather, and be sure that the hole in the center of the string will just admit the string. Next, thoroughly soak the piece of leather, then upon some smooth surface, as a flat stone, stamp the leather flat upon its surface, being sure that there is no chance for air to get under the leather. Now gently draw the string with your hand. This will raise the central portion of the leather, and cause suction under its surface. You will now find that you can lift a stone of several pounds' weight, if all has been done rightly.

This is precisely the way that a bee clings to glass and other smooth surfaces. Returning once more to the engraving, the little fan-like arrangement, C, answers the purpose of the leather. B is a pair of arms that spread out the little disk flat upon the glass. The little muscle, A, answers the purpose of the cord. Now, when the bee wishes to cling to glass he secretes a liquid (which has the same purpose as the soap upon the hands) under this little fan-like surface; he next spreads out this little fan with the muscles at B; then pulling the little muscle, A, he lifts up the center of this little disk. There! don't you see we have something about like the boy's stone-lifter? This produces what is sometimes called *suction*; and the whole apparatus is termed a *sucker*.

To illustrate to the "wee" folks what suction is, take an empty bottle, and draw out a part of the air with your mouth. You will find, after having done so, that your tongue will be drawn into the bottle. This is what draws a bee's foot to a pane of glass.

There, now, boys and girls, have I made it plain? I purposely dwelt upon details, so that our little friends might understand.

Perhaps I should add, for the benefit of the older ones, that there is something at E, which might answer for a valve, and that, when it opens, it allows the air to enter C, and thus free the bee. Or, it may be a gland for the secretion of the fluid that I referred to in the above. But these are only conjectures, and I have not been able to prove either.

ERNEST R. ROOT.

P. S.—I have just received a little note from father Langstroth, by way of encouragement in my microscopical work. Among other things we are glad to learn that he is feeling better. His letter is below:

E. R. R.

Dear Ernest:—I am very much pleased with your admirable drawing of the joint of the bee's leg, and the remarks accompanying it. I should judge that you have a very decided aptitude for such nice work, and there is a wide field open to you.

I hope to meet your father at the Detroit convention. I have been threatened with another attack of my old head trouble, but am better now than for

some weeks, and I hope to send the conclusion of "Observations on Drones" in season for the 15th. Oxford, O., Nov. 6, 1885. L. L. LANGSTROTH.

KIND WORDS FOR ERNEST.

BEING "EARNEST" FOR THE SAVIOR.

MR. ROOT:—I mean Mr. E. R., not Mr. A. I., this time, although I have addressed my envelope to the latter. Well, Mr. E. R., I have just finished reading your hints to the juveniles, on letter-writing, so I will not offend your royal highness by commencing my letter thus: "My pa keeps bees, and has a cow and a calf," and so on, to the end of the list; though my "pa" has the good fortune of possessing the "busy little workers," and also said "cow." Well, now, my real motive in writing this letter is this: When we received GLEANINGS for the 15th of Sept., my little blue-eyed baby-sister was eager to have the juvenile department read to her. When she found that you were to have control of that department, instead of your father, she exclaimed, "Oh dear me! I just know Ernest" (for I am forced to say, that when we speak of you in our family circle we use your name, without the prefix Mr.), "will be more exacting than Mr. Root." She continued to talk of it until we received GLEANINGS for Oct. 15. After hearing your kind words to the juveniles read, she laughed heartily, and said, "Well, I declare! Ernest is a real funny boy. I think I shall like him hugely. I am going to try his plan, in regard to that bee." She was so enthusiastic that she went right out in the apiary, and secured a bee; but, there—I must not tell the result, for she is going to write and tell you all about it, and it would not be fair for me to take advantage of her, and tell it.

Friend Ernest, I trust that God will bless you in your efforts to aid your kind father. God bless him. His name is always mentioned with love in this household. I am sure you will win the hearts of the dear little ones. As I am a little over 15, I shall not expect a book; besides, I do not think my letter contains much information; but if you think my little note worthy of publication, put it in the juvenile department. Don't fail to give us that talk on a bee's leg.

ETTIE.

Church Hill, Miss., Oct. 24, 1885.

Ernest's reply:

When the paternal "A. I." handed the above to "E. R." the younger, with a half playful, half serious remark, "Now see what you have got to take," and still further, when the aspiring sonship read the fore part of the letter, the title of "Royal Highness" began to wax sore heavy, and he repented that he had not kept out of the said corner, where he was likely to be cornered up—that corner where his "pa" was wont to stand. On reading further the youth's spirits began to revive, and he seemed like his former self.

Yes, friend Ettie, to be truly "Ernest" for the Savior is the highest title I care to attain; and may God help me to be a constant aid to that father who has been too long overburdened with cares.—Thanks for your kind words. We shall be most happy to receive the results of the blue-eyed sister's experiments. The talk on a bee's leg will appear in another column.

Every boy or girl, under 15 years of age, who writes letter for this department, CONTAINING SOME VALUABLE FACT, NOT GENERALLY KNOWN, ON BEES OR OTHER MATTERS, will receive one of David Cook's excellent five-cent Sunday-school books. Many of these books contain the same matter that you find in Sunday-school books costing from \$1.00 to \$1.50. If you have had one or more books, give us the names that we may not send the same twice. We have now in stock six different books, as follows: viz.: *Sheer Off, The Giant-Killer, The Roby Family, Rescued from Egypt, and Ten Nights in a Bar-Room.* We have also our *Homes, Part I and Part II.* Besides the above books, you may have a photograph of our old house apia, taken a great many years ago. In it is a picture of myself, Blue Eyes, and Caddy, and a glimpse of Ernest. We have also some pretty little colored pictures of birds, fruits, flowers, etc., suitable for framing. You can have your choice of any one of these pictures or books for every letter that gives us some valuable piece of information.

"A chiel's amang ye takin' notes;
An' faith, he'll prent it."

I AM glad to say that you little folks are going to help me out in the problems which I presented last month. However, it is a little late in the year for very many of you to report; but perhaps you can remember something in your experience that will give us a little light. I don't want you to give it up, as you are just the ones to tell us about it. Some of the big folks haven't the time or patience to work these things out.

I propose to give you another problem which you can answer for yourselves the present month. It is nothing of very great importance, but it will help you to be observing. Suppose you find out how a bee walks over the combs; that is, what portion of his leg does he use? Does he walk on the extreme end of his foot, or what part does he use? It probably will not be convenient, at this time of the year, to see just how they walk over the comb itself; but I will tell you a way that will answer just as well. Cage a few bees in a queen-cage, then with a magnifying-glass, or even with your eyes alone, notice how they walk over the meshes of the wire cloth. The meshes will answer for the comb. It is real funny to watch their little feet trip lightly over the wire. Sometimes you surely think they will make a mistake and fall off, so rapid are their movements. You must look sharp, or you will not see how they do it. While a bee is standing still, see what a funny little foot he has. Next, cage a few bees in a small box with a glass top. Then you can see how their little suckers cling to the glass as they walk on it. In another column I am going to tell you more about this tiny little foot, and I want you to see if I am right, because may be I might make a mistake.

We also want reports of how your papas' bees did this season. How much honey did

they bring in, and how many swarms go into winter quarters? Are they outdoors, or are they in winter hives on the summer stands? Some of your papas are big beemen, but they are one of those kind of quiet sort of men who don't write much. You are just the ones to tell us. How many of you shall we hear from next month?

Perhaps you would like to know about our baby-rabbits. Little sister Caddie has kindly consented to tell you, and her letter is below.

HUBER'S BROTHER.

THE FRADENBURG RABBITS; A REPORT OF, BY
CADDIE—ANOTHER BLUE EYES.

We had thirteen or fourteen little rabbits, but an old cat killed all but three, and Blue Eyes and Ernie have to shut them up every night, or the cat would get them too. We know it is a cat, because pa saw a cat in there one morning. These rabbits are about a month old now, and we have some more only two or three days old. Blue Eyes saw those before they had any fur on, and she said that they looked like baby-robins. Those that are a month old are the prettiest, because they have their eyes open, and can run around. Two of the month-old ones are a creamy yellow, and the other is gray. It is hard to tell what color the youngest ones are, because they haven't much fur yet.

Medina, Ohio, Nov. 7, 1885. CADDIE ROOT, age 7.

A LITTLE VILLAGE.

We have two swarms of bees. My papa sent and got one of your smokers, and he thinks it is real nice. Uncle Andrew has lots of bees; and when you look at the hives it seems like a little village. The bees like to suck the honey out of the flowers in my little garden.

MARY EDNO JENSEN.

Saxeville, Waushara Co., Wis., Oct. 13, 1885.

AN INCUBATOR FOR HATCHING QUEEN-CELLS.

I am a little boy 12 years old. My father has a hot-water incubator for hatching eggs. The temperature for hatching is 102° to 104°. Can I hatch queen-cells at that heat?

J. BAKER SMYLIE.

Caseyville, Miss.

A temperature of over 100° is rather too hot for hatching queen-cells. Between 90 and 100° is about right. See A B C.

BUCKWHEAT INJURED BY FROST.

My brother has four colonies of bees. They did well for this year. They are doing pretty well on the buckwheat. The frost has killed the buckwheat considerably. We have about 200 Simpson honey-plants, and about 150 spider plants. I like to work with bees real well. Pa made two artificial swarms this year; he did well with them, only they did not want to accept the queen at first.

Woodstock, O.

PERL Z. CRANSTON, age 13.

GETTING STUNG IN THE DARK.

My pa has no bees, but we live close to grandpa, and one of my uncles has got 40 stands of bees. Sometimes I go to help him fill up honey-bottles. One night I was down in the cellar with him. He went to get something to put honey in, and left me in the dark. While he was out, a bee stung me on my neck. Uncle Henry told me to be still; but when the bee stung me I ran up the steps crying. Uncle laughed at me.

VIRGIL PATTERSON, age 9.

Humboldt, Neb., Oct. 19, 1885.

NOT MUCH BUCKWHEAT HONEY, BUT "A GOOD BIT OF BASSWOOD."

My pa has ten swarms of bees. I claim one of them. They swarmed twice this summer. It was bad weather in August, and we didn't get much buckwheat honey, but we got a good bit of basswood.

EMMA DATERRER.

Newtown Mills, Pa, October 5, 1885.

50 GALLONS OF HONEY FROM 22 BOX "GUMS."

I am a little girl 8 years old, and I live on Red River. My pa is a farmer, and he is a beginner with bees. He has 22 hives, and they are old box gums. He got 50 gallons of honey last year. My sister lives about 200 yards from me. She has some bees too, and her bees came down here to rob pa's bees, and pa's killed them just as fast as they went into the gum.

LIZZIE DUDNEY.

Collinsburg, Bossier Parish, La.

FROM 41 TO 70, AND 3000 LBS. OF HONEY; REPORTED BY A JUVENILE.

My papa has kept bees about six years. He commenced this season with 41 stands; increased to 70, and got 3000 lbs. of comb honey in 1-lb. boxes. He sold some at home for 15 cts. per lb., but sent the most of it to New York. I have one brother. His name is Royal Jasper. We go to school. I have left off at the head of my spelling-class every day for two weeks.

EVA GREGG, age 6.

Galilee, Wayne Co., Pa., Oct. 22, 1885.

HOW A LITTLE GIRL MAKES HERSELF USEFUL.

My papa has 25 colonies now. They didn't swarm any this year, but made a good deal of honey. Papa generally takes from 100 to 200 lbs. of honey per year. I help him with his bees. I could climb a ladder, saw off the limb, take down the bees, and hive them before I was 10 years old. Pa buys all his hives of you. He and I are coming out to see you and your bees and little Blue Eyes.

MARY C. MILLER.

Millersburgh, Ky., Oct. 14, 1885.

We are very glad to know, Mary, that you are going to pay us a visit. When you come, be sure to tell us that you are the little girl who said in the Juvenile journal she was coming with her father to pay us a visit.

"A BIG FLY BIT HIM."

Papa has 15 swarms of bees; he commenced with 9 swarms. He would have had 21 swarms, but 6 went away. I had a wart on my hand, and I put coal oil on it twice, and it took it off. I have a little brother 3 years old. One day he went out to play. Pretty soon he came in crying, and said that a big fly bit him. A bee had stung him.

Jefferson, O.

JESSIE HERRICK, age 10.

Very good, Jessie; but how could you prove it was the coal oil that made the wart go off from your hand? Warts come and go, quite frequently when nothing is put on, do they not? You may be right; but I am anxious that you children shall learn to use reason, especially in this matter of remedies for various ailments.

REPORT DISCOURAGING.

The bees have not done much this season, and have not made much honey; but next year I hope they will do better. Papa has taken the honey from our bees, and now they are full of honey for the winter, so papa will not have to feed them. The

other morning George and I went out and got 43 fish, and they were just as fat as they could be, and we smoked them.

EVA S. GLAWSON.

Hawk's Park, Fla., Sept. 28, 1885.

Glad to hear about the fish, Eva. But, what do you mean by "smoking" them? That is something we don't quite understand here. May be you can tell us about it.

A LESSON TO BE LEARNED FROM THE BUSY BEE.

Our neighbor keeps bees, and I have been over there to see the bees swarm in a hot summer's day. It is a good lesson for little children to go into a beeyard and see the busy bees work in a sunshiny day. It is a perfect buzz all the day long, by the busy bees going forth to find honey-flowers, and bringing back to their hives particles of nectar which is made into honey in the comb; and when the cell is filled by the bees they cap the cell over with a piece of honey-comb, then it is finished.

Tracy Creek, N. Y.

BERT S. WHITTAKER.

50 SWARMS AND 2000 LBS. OF HONEY; SOMETHING ABOUT CARP.

My papa has about 50 swarms of bees this year. They are getting along all right. This summer my papa took off about 2000 pounds of honey. He keeps carp. One day he went to his carp-pond and caught a carp and brought it to the house and showed it to my little brother Irving, and he thought it was nice, and he laughed. He is $2\frac{1}{2}$ years old.

EMMA JENSEN, age 11.

Valparaiso, Nebraska, Oct. 17, 1885.

Why didn't your papa weigh the fish, and tell how much it weighed, Emma, and how old it was? We all want to know what can be done in this matter of carp. We should also be very glad of a report from those who are using the carp for food. Are they really good?

FOOT-POWER SAWS NOT PRACTICABLE.

Papa and I have been keeping bees for about four years, and have been following your advice. We did not have much success with the old-fashioned way, but are doing better now. Last winter we made a foot-power saw for making hives, but it was such hard work sawing that we attached a horse-power and made 12 nice hives. I would not advise any one to attempt making many hives by foot-power. Two years ago we had only three colonies, and now but 16. My colonies were very weak last spring, but papa gave me some combs containing eggs and young bees, with which I made it a strong colony.

CHARLIE GREER, age 11.

Paris, Tenn.

A JUVENILE TELLS HOW LONG A BEE LIVED AFTER IT STUNG HER.

I am a constant reader of your journal. My pa takes it. He has five hives of bees. It was said in GLEANINGS that some one should try to find out how long a bee would live after it lost its sting. I tried it. It stung me in my dress, and it left the sting in the cloth. I gave it all the honey that it wanted, and it lived just seven hours.

HULDA M. MYERS, age 13.

Mt. Cory, Hancock Co., O.

Well done, little friend. You have indeed given us something valuable. You may now, in addition to the book we sent, take your pick of any thing on the ten-cent counter. Let us hear from other juveniles upon

this point; and if they do as well, we shall be glad to grant them the same privilege.

HOW WILLIE STARTS INTO THE BEE BUSINESS AGAIN.

My pa has 68 colonies. I had a swarm, but the other bees robbed them this summer, and they died. Mr. Dukes found a bee-tree this summer. Pa helped chop the tree and fit the bees up for him, but it was too late for them to gather enough honey for them to live through the winter without feeding, so he told pa if he would come and get them he might have them. So we went and got them, and then pa gave them to my brother and me. You see, Mr. Root, by this letter we are going to try the bee business again.

WILLIE BOLTON, age 10.

Stanley, Ohio.

DOWN IN SUNNY FLORIDA, WHERE ORANGES GROW.

We have no bees. I should like to get one or two hives of bees, so we should not have to buy honey. The orange-trees are white with blossoms. The bees get plenty of honey from the blossoms. I am going to school now. I like it very well. I have learned a great deal. I wish it were about four months longer. It is about the only chance I shall have to go. We have plenty of fish and oysters. A few weeks ago I saw Mr. Muth pass our house. I was very glad to see him.

Hawk's Park, Fla.

GEORGE F. GLAWSON.

Do you really mean, George, that it was our friend C. F. Muth, of Cincinnati, whom you saw? I didn't know before that he was visiting in Florida. We wish he would write to us some letters, and tell us about his trip.

A JUVENILE TELLS HOW TO MAKE A HOME-MADE EXTRACTOR; HOW TO HATCH A QUEEN-CELL IN A HEN'S-EGG SHELL.

My brother has 21 swarms of bees; they have done well this summer. I do not know how much honey they made. My brother made an extractor. He took a bucket and put a stick across it. Then he took a piece of sieve and put it on a square wooden frame, and fastened two of these frames to a round iron running up through the center of the bucket, and through the stick on top. He then put a wheel on the end of it, and a crank to turn it round with. One day I had a queen-cell in my hand, and the queen came out of it. We hatched a queen under a hen, in an egg-shell.

KATIE BRIGGS.

Deposit, N. Y.

I think, Katie, your brother must have had a pretty large bucket; that is, if his extractor will take frames of the ordinary size.

A LITTLE GIRL WHO LIVES NEIGHBOR TO FRIEND W. S. HART.

I thought I would write you a few lines. I got the books that you sent me. They are nice books to read. The little book has some pretty stories in it. Mr. Hart is our friend. He has a nice lot of bees. He gets a good price, but he has nice honey, I think. Papa used to keep a few hives of bees, but he does not keep any now. I will send you some orange-blossoms.

MINNIE MENDEL.

New Smyrna, Fla.

Thank you for your promise of orange-blossoms, Minnie. We should be real glad if you would give us a good long letter, telling us more about Mr. Hart's apiary, and what he is doing. We would willingly pay

you for such a letter. And, by the way, the little boys and girls who live near bee-keepers could do us quite a service by visiting them and making reports of what they see.

WHAT IS IT?

My grandfather had some potatoes under some straw, with just the least bit of dirt over them, and they do real well; but what I want to tell you is, that in under the straw was something curious. I do not know what to call them. They are about the shape of an egg, a little smaller than a common hen's egg. He found one about two weeks ago, and in three or four days he found three more. They were all rooted together with little fine roots, and he buried them in the ground. He kept one of them to show to folks. In about one week he poured some warm water over them. The next morning both of them were up. He buried the other one then, and poured warm water over it. It came up in a little while. They were about five inches tall, and about half an inch through the bottom, and about a quarter of an inch through the tops. They look like the stem of a toadstool.

My grandfather was 87 years old in September. My brother got an Italian queen, and in 21 days there were young bees in the hive.

Woodstock, O.

PERL Z. CRANSTON, age 13.

From your description, Perl, I should suppose it was a sort of mushroom that your father found. May be it is the mushroom we use for food; but I didn't know before that they could be transplanted as you mention.

A CASE OF ROBBING; A SWARM THAT SMOTHERED FROM BEING CLOSED UP.

We had 8 swarms this summer, but we have only 7 now. Our neighbor has 14 swarms, and we are bothered with them all the while. Pa says they carry the honey out of our hives as fast as our bees can gather it, and he has to feed them for the winter. It was a very warm day on the 28th of September, and the robbers were so strong that pa had to shut our hives, and it was so hot that one of the swarms smothered, and he took the hive and carried it down cellar, for he thought that he could save the bees; but on opening the hive he found almost all the bees were dead, and their combs were all melted down.

KATIE ZEHR, age 10.

Indian River, Lewis Co., N. Y.

Friend Katie, your papa learned a lesson in regard to the danger of shutting bees up when the weather is very warm. It is never safe to fasten bees in, especially when they are excited by robbing, or something of that kind, as yours were, unless they are very closely watched.

A SWARM THAT HUNG ON A LIMB 6 DAYS.

I was up to my Uncle John Noftisier's, and we went out. I saw a swarm of bees hanging on a limb. I asked why they didn't hive them, and they said they hived it twice already and it didn't stay in the hive, and then they looked and saw that it was a swarm that he got in the spring, and had no more honey, and had left the hive. It had been hanging there three days when I was up there, and he said that it stayed there three days more, and then they starved and fell off.

LENA ZEHR, age 12.

Indian River, Lewis Co., N. Y., Oct. 23, 1885.

Why, Lena, wasn't that cruel, to let that

great bunch of bees starve? I am sure I could have hived them so they would stay, especially when they were starving to death where they were. Suppose you had fixed the hive right where they clustered, and then given them some syrup in a feeder; they certainly would have gone to work, and fixed themselves for winter, had you given them such a chance.

HOW CONRAD MADE A HIVE FOR HIMSELF.

My brother Christian had 34 colonies last fall, and he has 25 yet. Several experiments which he tried caused the death of some colonies. I began to keep bees last year. I first took a few old boards and sawed two alike for the ends, then two for the sides. My brother Christian nailed it together and we put the bees in. We took an old top of a hive for the lid, and they did pretty well in it. I dug a hole in the ground so that one end was open for the entrance, then set the hive in, and put sawdust on the ground; then we had no bottom in it. Then I began to feed them with sugar till it was time to quit for winter. I packed them with straw outside and chaff inside. CONRAD E. WECKESSER, age 11.

Marshallville, Ohio.

Well, Conrad, that is a rather novel hive of yours, with nothing but dirt for the bottom. I am not sure but it would answer nicely during warm weather. Of course, there would have to be a ditch dug around the outside of the hive, so the water from storms would not get in and make it nasty and muddy.

A SWARM THAT LEFT THE HIVE, AND BUILT COMB UNDER THE HIVE.

Pa had 7 stands of bees, and they all died but one. I don't know what was the cause, but I guess he did not tend them. I am staying with my sister. They have five stands of bees. Bees here gather honey from white clover, basswood, Spanish needles, smartweed, and goldenrod. I love to read the little letters. Did you ever hear of a swarm of bees that left the hive, and built comb under the hive? Our neighbor had one last winter, but they froze when cold weather set in. IDA M. DEAL, age 13.

Herborn, Ills.

Yes, Ida, I have heard of swarms of bees going under the hive, and building combs, as you say. Sometimes it is because their owner does not give them room enough inside of the hive to store the honey, and in that case it indicates bad management. It is like the old adage of not having your "bowl right side up when it is raining porridge." When the honey-flow comes that induces bees to do all that, we surely want to have plenty of surplus boxes on, so the bees may put it in the hive in the nicest shape. Sometimes it is caused by the queen crawling under the hive instead of inside of the hive, when a swarm is hived. In that case there would be nothing in the hive at all, though I hardly need tell you that this also is very bad management.

FINDING A BEE-TREE IN THE NIGHT.

Since I wrote you last, I do not know what to write about bees. Papa is now putting grapevines between his hives, to shade them in hot summer days. I think it is a good plan, to keep any one from getting the grapes before they are ripe. Papa has found three bee-trees, and I found two. I found

one while hunting one night. I saw something white while I was passing by a large tree, right at the ground, while my dog grabbed out some of the comb; but the bees did not sting him, because they were too cold. Papa and myself went back there the next day and nailed some bark off from another tree of the same kind over the hole, and left only one little hole for the bees to come out. He said that he did this to keep any one else from finding it. He is going to get them in the spring. I like hunting in the night, very much. CHARLIE HARDIN, JR.

Very good, Charlie. I suppose you mean the tree had an opening near the ground. Bees do sometimes occupy such places, but not often, because such a place is too convenient for their many enemies. And so the white comb was partly visible through this hole. Had I been your papa, I think I would have cut the bees out and carried them home, in order to make a sure thing of them.

A NOVEL METHOD OF CREATING A "HOME MARKET," HOW THAT HALF-POUND OF BEES TURNED OUT.

I want to tell Huldah Williams how our mamma manages so as to let us have all of her honey, and sell it too. She sells it to papa. Isn't that a "home market"? In Sept., 1884, she got $\frac{1}{2}$ lb. of bees from you, which were her first bees. In November she took them out of the little hive, and put them in a big one, with chaff cushions on each side, and they got along very well. In warm weather she would go to them; but one day in March she went to them, and they were all stiff, and looked like dead bees. They did not have a drop of honey, so she laid the two frames in the sun, and sprinkled them with sugar-water, and in a few hours they were all alive and in the hive again. She fed them till they could get honey. They did not swarm this summer, but there are many bees in that hive. They filled the bottom of the hive with honey, and then filled the top, and that is the honey we laugh about mamma selling to papa. The honey was crosswise and every way, so mamma could not draw out the frames; so she asked papa to come and lift the top story, honey and all, off, and she put empty frames on. Papa is afraid of bees, so he had on a veil and gloves, which made his hands clumsy; and after all the bees were off, and he was taking the honey to the house, he let it fall, and, such a mash! We got pans quick, and saved the honey. There were young bees in the middle.

What will keep the queen out of the upper story? and how can mamma make them build straight comb? I am always with her when she goes to them, and am not afraid, though they get in my hair sometimes, and sting. In May a swarm of black bees clustered on the hedge, and mamma and I put them in one of your hives, so we have got two hives of bees. Please excuse my long letter. I only wanted to tell H. W. how she could get a plenty of honey, and I have said too much about other things.

PEARL FERGUSON, age 10.

Macon, Miss., Sept. 26, 1885.

Thank you for your good letter, friend Pearl. Your mamma has learned a lesson in regard to the importance of seeing that the bees have plenty of food. Do not by any means let the industrious little fellows starve to death. She chose the proper way to bring them to life. You *did* have a mess when your papa dropped the honey, did you not?

I think you will have no trouble with the queen in the upper story, if you use section boxes according to the modern methods of management. This matter, and that in regard to straight combs, are very fully treated in the A B C book.

TOBACCO COLUMN.

THE TOBACCO REFORM AMONG THE WOMEN.

AS it seems to do you so much good to know that people are stopping the use of tobacco, and I believe I hate the habit as bad as you ever could, I report for my wife and her two sisters, Mary and Nancy Israel, who have used it for the last ten or fifteen years. My wife and Mary quit about five years ago, and have become great opposers of the habit. Nancy quit this summer, and thinks she can hold out faithful to the end. My wife thinks it has been an injury to her health.

If you wish to send one smoker to all three, you can mail it to me, as one will do for all. If you have any lectures that will be of any help to persuade any one to quit, send some if they are free, as we have a brother we wish to have quit.

Best, Buncombe Co., N. C. R. L. PATTON.

Friend P., we rejoice to hear of the great work you have taken up, and we are glad to see the courage with which your wife and sisters come out and declare their determination to break off from this evil habit. May God bless and strengthen you all. We most gladly send you a "Dose of Truth," and a smoker also.

I saw in GLEANINGS that you proposed to give any one a smoker who would quit the use of tobacco. I have quit the use of it; and if I commence again I will pay you for the smoker immediately.

Meridian, Texas, Oct. 1, 1885. E. T. PERCIVAL.

I have quit the use of tobacco, both chewing and smoking, after using it for fourteen years. Will you please send me a smoker? If I use tobacco again, I will pay for the smoker.

Hubbard City, Tex., Sept. 28, 1885. M. TAMEK.

Seeing your offer to those who quit the use of tobacco, and who expect to continue it, after having been a user of it for 18 years I will solemnly affirm, that I will never use it in any way; if I do, I will pay for the smoker.

Sonora, Ky. HENRY CAUCH.

I have quit using tobacco, and don't wish to begin again. I suppose you will send me one of your 50-cent smokers, for I have some hybrids that are too cross to be endured; and if I begin using again I will send you pay for the smoker.

Huntington Center, Vt. HENRY E. SWEET.

Mr. T. B. Franks says I must tell you that he has quit using tobacco, and intends to stay quit; and if you will send the smoker gratis he would like you to send him one.

F. J. BOSTICK.

Greenville, S. C.

Please send me two smokers—one for William Chamblers, and one for C. B. Williams. They both have quit using tobacco, and say they will pay for the same should they ever use it again. They got me to write for them.

G. W. JOHNSON.

Stinson, Ga., Aug. 9, 1885.

A friend of mine, who has a few stands of hybrids, and cross ones at that, has been an inveterate smoker for a number of years. After reading a few numbers of GLEANINGS he has given up the habit for some time past. He now requests me to write to you for a smoker, and should he commence the filthy habit again, he will pay you for the same.

Carlinville, Ill. J. A. BLAEUER.

"QUIT TO STAY QUIT."

I see you offer a smoker to any person who has given up the use of tobacco. I have done so. I have used the weed for 30 years, and have quit to stay quit. I think it is one of the great evils of our day, for men to come down so low as to use the unhealthful, filthy stuff. If you think me worthy, send the smoker. I will pay for the same if I use tobacco again.

JAMES W. STONEBRAKIN.

Wild Cat, Carroll Co., Ind.

BY THE HELP OF GOD HE WILL NEVER USE IT AGAIN.

A neighbor of mine has put away tobacco after being a slave to it for 22 years, and says by the help of God he never will use it again. He is just starting in the bee business, and says as soon as he is able he will subscribe for GLEANINGS. He got me to ask you to send him a smoker; and if he ever uses tobacco again, he will pay you for it. If he, Mr. S. H. Zouger, fails to pay for the smoker, I will, provided he resumes the use of tobacco.

Hickman, Ky., Oct. 5, 1885.

J. O. BARNES.

Glad to know you are in the missionary work, friend Barnes; and I don't know any better way in the world to make a man stick to his pledge than to have some friend vouch for his honesty in the matter.

HE SPENT ENOUGH MONEY FOR TOBACCO TO BUY A LARGE APIARY.

I have been the worst slave to tobacco smoking I have ever met with. I kept the pipe in my mouth almost constantly; but after nearly destroying my health I was induced to quit. It cost me about twenty dollars a year. I have spent enough money for tobacco to buy a pretty large apiary, the way bees can be bought now. I followed its use almost twenty years. I have tried to quit it a good many times, and failed; but it is over two years since I quit it for good. It is no temptation to me now. I know all who will, can quit its use. If you think I deserve a smoker, I shall ever feel grateful to you.

L. H. ROBEY.

Worthington, W. Va., Sept. 25, 1885.

QUITTING TOBACCO FOR THE SAKE OF THE BOYS.

I am much pleased with your journal. I do not intend to try to get along without it again. Do you sow any thing in the fall to make early feed for the bees? My husband has thrown away his tobacco, and does not intend to use it again, because the little boys wanted some. He says if you give a smoker to all subscribers who stop using tobacco, you ought to send him one. If you will send him one to gratify him, I will try to get you five new subscribers between now and the first of the year.

Bennett, Neb., Sept. 19, 1885.

J. ROSS.

We send a smoker, my good friend; but I should rather have your husband's promise than to have the five new subscribers, although we are always glad to have additions to our list. Quitting for the boys' sake, I should say, is next thing to quitting for Christ's sake. Is it not so?

OUR HOMES.

We will not have this man to reign over us.—
LUKE 19: 14.

EVERY few days something occurs to remind me that I am growing old. People speak of me as belonging among the class of old people, and I find myself telling the children what happened, not only 25 years ago, but 30 and 35 — yes, almost 40. There are a few events that I can distinctly recall to mind, that happened 40 years ago. I have been employing boys and girls for almost 30 years; but of those who worked for me 30 years ago, or even 25 years ago, there is not one remaining with me now. I have just made some inquiry among our hands, for the matter came up at our noon service, and there are two who have been with me for 17 years.

Well, just 23 years ago this fall, a boy came to me for a job, just as boys come even now every little while. He came from the country, but he had good parents, and his step-father was a minister. I happened to be needing a boy about then, and, oh how I *did* want a *good* boy! I had tried a good many boys, but they were of the sort who lay things around and lose them, tip over things and break them, and need so much showing, that it was almost with anguish of spirit that I thought about trying another one. He wanted a little better pay than I had been in the habit of giving. I told him so, but he replied something like this: —

“Mr. Root, if you will let me go to work, and you say, when Saturday night comes, that I have not earned the price mentioned, I will take whatever you say is right, and no hard feelings. I think I can save you enough to make up the difference, if you will let me try.”

The last sentence struck the right spot, and I was glad to have him undertake it on those terms. I can not remember what the price was he wanted, but it was somewhere between $7\frac{1}{2}$ and 10 cents an hour. I will tell you how he started out to save me $2\frac{1}{2}$ cents an hour. I love to tell it, for there is a good moral to it. He got hold of a broom, and I soon discovered that he was an adept in sweeping. He loved his mother, and I presume he had helped her about her housework, and she had taught him how to sweep properly. While he was sweeping he hung up the tools that he found scattered around. If there was not a place for them, he proposed to me that they should have such and such a place; and if they were not made to hang up, he fixed them so they would hang up nicely; and in this way he went through our whole establishment.

When he had got through in the upper rooms he asked permission to “slick up” the cellar. He found an old iron sink in the cellar, covered with cobwebs and slime. He scoured it out with a piece of brick, brushed it off, and then went over it with a cloth. He scoured the wash-basins until he made holes in some of them, then he put up some stout nails for them to be hung on. He fixed a cupboard for the lamps; and when it began to grow dusky where I was reading

my letters, toward the close of the autumn days, a lamp was placed before me, without my asking for it. The chimney was spotlessly clean; the lamp was filled, but not so as to run over. The wick was trimmed, evidently by an expert in caring for lamps; and when he was done, his scissors and arrangements for cleaning and caring for lamps, as well as the coal oil, were all nicely put away. He even went into the dark corners of the cellar and slicked those out; and whenever it came time for his meals, his face was washed, his hair combed, and clothes dusted off, until he looked like a bright, happy boy, which he was. Other boys and girls had considered this kind of work the work of a servant; but he seemed to delight in being a servant. If anybody twitted him of it, he answered back promptly and smilingly, that this was just exactly what he *was*, and that he felt proud of his office; that I had paid him money to serve me, and he *liked* to work where he could show every day that something had been done when night came.

In clearing out and slicking up one day he found a lot of old-fashioned watches, or watch movements, rather, in an old drawer near the watch-repair bench. One evening, after his work was done, and my lamp was placed before me, giving its accustomed clear, steady light, he made a remark something like this:

“Mr. Root, I wonder if you would have any objections to my working a while evenings with those old watches in that drawer.”

I told him that, as they were of no value to anybody, he might do as he pleased with them; and if he broke them all up, they would be worth just about as much. He accordingly worked away at them night after night; but instead of breaking them, he succeeded in making nearly all of them keep time. Although I had formerly been a watch repairer, I gave him no instruction. He said all he wanted was the tools and the watches. Pretty soon he began to repair clocks, and did it as nicely as he did the sweeping. Why, my friends, the boy or girl who is an expert and enthusiastic *housekeeper* can do almost any thing there is to be done in this world. He was very soon able to do almost any kind of work done in the shop. His wages went up rapidly, first a cent per hour at a time; but he soon got into the teens, where he had 15 cts. per hour; then 18, and, if I am not mistaken, by the end of his second year he had 20 cts. an hour. Then he went to a larger city to work for a rich jeweler, and after a while he married one of the girls who worked for me — one of his old shopmates, and together they started life in a new and growing railroad town. We will leave him there for a little time.

During the two years that he worked for me I was not a Christian. I never said a word to this young friend about the welfare of his soul. I was glad to see him spend his evenings in the way I have told you; and when he told me his step-father was a minister, I presume I thought my apprentice ought to be a good steady boy on that account, but I gave him no word of encouragement in that direction. He was much at-

tached to me, and I believe he considered me to be a good man. Perhaps the fact that I held aloof from Christian people and the churches, encouraged him in thinking there was no particular need for him to be a Christian. Is it a matter of very much importance, any way? Dear reader, let us step over the 23 years.

Day before yesterday, at the close of the Sabbath sermon I inquired of the sheriff's wife if there was any one in the jail to see me.

"Yes, there is another. He has been in only a day or two. His name is —. Why, they say he used to work for you once. It is Mr. —."

"Why, no; is it really true, that my old friend — is in jail? I have heard a great many times that he had got to be very intemperate, but I had no idea that it had really come to this."

After Sabbath-school it was with a beating heart that I stood before the iron door while my friend undid the fastenings and ushered me in where I had gone so many, many Sundays during the past ten years. My old apprentice was glad to see me, as I knew he would be; but, oh how changed he was! This journal goes regularly to the jail, and I shall have to be careful what I say here, for his eyes will probably meet this. May God help me to remember that, while I am telling this simple little tale to you as a warning, I may remember also the soul that will see it too, and possibly suffer while he sees this record on a printed page.

He was not ready to admit that intemperance was the cause of his trouble, for what intemperate man is? A watch had been left with him for repairs; but when the owner came for it, it could not be found. He refused to pay for it, and was sent to jail. After I had talked a little while with him I reverted to former days, and asked him if he remembered how he used to help me about sweeping out and slicking up. His old smile and his old vivacious manner came back, as he rose up and called me to come and see what he had been doing since he had been in prison. He was the sole occupant, and so he had his own way. He had swept out the cells, and scoured the stone floor. He had gone over the sink and washing utensils, just as he had when a boy. By way of pleasantry he informed me that he had scrubbed one "coat" off from the windows, and that he was going to put on the "finishing touches" next day. I do not mean to say that the jail was badly cared for, by any means, for it was as well taken care of, or better, than such places usually are; but I knew the sheriff often had trouble to get the prisoners to scrub the floor and keep the place looking ordinarily decent. Here was one prisoner, however, who did not need even the asking to do this kind of work. Poor —! His prevailing trait was there still; and although he showed plainly the marks of the years that had passed, he loved neatness and order as he did in his childhood. He used tobacco, of course, and was inclined to argue with me when I intimated that it *might* not be just the thing. He loved his mother and his *Bible*, so he

said, but he was not willing to follow the Bible teachings, although he kneeled by my side and responded by an amen when I prayed for him.

Now, my friends, let us consider the text at the head of this talk; and let us consider, if you choose, the great question as to how it comes, that young men of such great promise do so many times turn out so sadly. Why should he be here in jail, when he might be a useful and respected member of society, filling some important place of trust and honor? Some of you may say that it was all owing to the fact that we permit open saloons throughout our land, and that whisky is responsible for his downfall, and the downfall of thousands of others. While I assent to all this, it seems to me that whisky is *not* at the *foundation* and *root* of the evil, after all. The young man need not have touched whisky. I feel quite certain, that, while he was with me, he had no taste for it, and knew nothing of its bondage. Why did he commence using it? What was the attitude of heart that induced him to touch a thing he had been warned against from his earliest recollections, just as you and I have, my friends? What should possess *anybody* to touch or tamper with intoxicants? I presume a good many of you will feel like saying outright, "It was the very prince of the powers of darkness *himself* who started him on this road," and I agree with you. *Satan* is at the bottom of intemperance, as he is at the bottom of every other evil, and there is never any danger, unless we choose, and choose voluntarily, to follow *Satan* instead of choosing to follow *Christ*. You may reject this, and our friend himself may say that he never *voluntarily* chose *Satan*. There is one thing certain, however, my friends—he did *not* choose *Christ*; and Jesus says, that "he who is not for me is against me." The fact that he had not chosen *Christ*—that he neglected to choose *Christ*, or that he *refused* to choose *Christ*, is almost equivalent to saying that he chose *Satan*. I do not mean to be fault-finding, and I do not want to reproach, for I, too, was guilty of the same charge during the whole two years that he worked for me. He knew that I was not for *Christ*, therefore I was indirectly in league with *Satan*. Had I been teaching *Christ* as vehemently as I taught and encouraged my young friend in habits of neatness and order, he might have been—nay, probably would have been, a professor of religion to-day.

Well, then, if this matter of accepting or rejecting *Christ* is something of such vital importance, how shall we know when we are straying from the straight and narrow path? To make the matter clear to you, as I see it, let us digress a little. When *Jesus* came into the world, men were very much disappointed in him. The Israelites—God's chosen people—were *greatly* disappointed. They were looking for a powerful earthly ruler—a rival of *Cæsar*, and they nursed up their revengeful feelings, and handed them down from father to son for centuries, looking forward to the time when they should, by the aid of this earthly ruler, trample the Roman power under foot. They had the

words of prophecy, telling them that Christ should be a man of sorrows, and acquainted with grief. But they forgot it, or ignored it. They would have it, that he was to be a man of the world. When he came and told them that his kingdom was not of this world, they were disappointed and disgusted. Pilate asked him if he was a king. He replied, "Yes, I am a king; to this end was I born, and for this end came I into the world." That they might not make any mistake, however, he added, that his kingdom was to bear witness unto the *truth*. He was to be the *king of truth*, and not a rival to earthly rulers.

Now, my friends, I wonder if it would sound harsh if I should say the time has been when *you* considered this matter of Christ, and turned away in disappointment; that is, providing you are not among those who are *known of all men* as a follower of Jesus. The subject, sooner or later, comes up to all of us. We are obliged to decide in regard to Christ's claims. We have said in our hearts, "We will not have this man to reign over us," or else we have decided we *would* have him to rule over us. Our boys who are growing up are deciding this question to-day. They are influenced greatly in their decision by the stand which their fathers and mothers, or employers or teachers take.

In talking with my friend in jail, he said he was a good deal surprised when he heard of my conversion; that he had somehow got into his head that I did not need converting. Most of my readers know what a blunder he was making. Perhaps, my friend, you have sons or daughters who are deciding this question now; may be it is a brother or sister. How shall you tell? The Jews refused to have Christ rule over them, because he forbade fighting with the Romans. He told them that, if his kingdom were of this world, then his servants would be expected to fight for him; but he absolutely forbade even this. When one of them struck at a Roman and cut off his ear, Christ used his miraculous power to restore it; but that miraculous power was never brought into action to save himself, nor even to convert the stones into bread when he was hungry. They jeered at him, and threw it up at him, while he was on the cross. "He saved others, himself he can not save." The idea, that any man who had unlimited power in his hands, and yet would not use it, even for self-protection, was so preposterous and utterly ridiculous, that they fairly hissed at such a thought. It was not the Jews only, but the Romans also — in fact, all nations of the earth, gathered there with one voice declared (when the character of the Savior was held up before them, and illustrated by such object lessons as only Christ could and did give), "Away with such religion! We will have none of it. By no means, and under no circumstances, will we consent to follow this man, or have him rule over us. No matter if he *has* performed miracles; no matter if he has even *raised the dead*; why doesn't he help *himself* now, if he *can* help himself? Do you mean to say that he *can*, but will not? Away with such folly!"

And the world rejected him in scorn, and turned their backs, and spit upon him, to indicate their fierce hatred and bitterness toward such a king and such teachings.

As I go over this scene, dear friends, it does seem to me as though the world has made progress since that time. Then, only two or three poor foolish women (as the world looked at it) stood by him. Yes, there was one man who braved the world long enough to stand near during his expiring agonies. But even that man, and those women with woman's faith, never even guessed, as it would seem, that this was not the *end* of his dominion and his power and his kingdom. Rejecting Christ *then*, was plain to see. It was a plain, simple act. How is it now?

When our young friend brought me my lighted lamp, as I told you about, and placed it on my desk so that I could read my letters, I was, at that very time, rejecting Christ. Do you ask how? Some of you know how plain it was made to me when my eyes were opened. There was a right-hand sin at that time that stood in the way of Christ. I knew it, and I knew I could not be a Christian unless I cut it off and cast it from me, as Jesus demands. I did not connect it in just the way spoken of in Matthew 5:30, but I knew there was an unwillingness in my heart to give up all and follow Christ. I had considered the matter well, and decided that *I would not have this man to rule over me*. I had determined to manage things myself in my own way, despite Christ's claims or *any* claims. I had not come to this determination with any *direct* purpose of wronging any one, or making any trouble anywhere; but still, that was just about what it amounted to. When my apprentice, with whom I was so well pleased, began urging to have his wages increased a little faster than my better judgment approved, I felt a little sorry to see him show just this spirit; but yet I did not think very much about it. When he a little later began to prefer to be out evenings, instead of working at his old watches, I felt a little more anxiety; and when he commenced to use tobacco, I could not help feeling, even though I was a sinner myself, that he was starting out in a way that did not promise quite right. By the way, what spirit is it that prompts a young man to want to go about the streets with a cigar in his mouth? Christ said his kingdom was not of this world. Now, it has seemed to me that a young man's first cigar seems to say more plainly, perhaps, than almost any one single act, "I am for this world." Certainly no young man who has serious thoughts of becoming a Christian ever began to use a cigar *because* of that decision. Some one has several times sent me a copy of a paper entitled *This World*. The heading is appropriate. The paper is published for the people of this world, and this world only. They might have put right under this title, "We will not have this man to reign over us;" and then if they had gone on to make a picture of the character of Christ, and had declared the teachings and sentiments of the paper to be in direct opposition to Christ's teachings, they would have hit it exactly.

I told you, a few months ago, of meeting a saloon-keeper in jail, and of trying to read to him some of Christ's teachings. When I got to that chapter about loving our enemies, and doing good to those who hate us, the thought was so fairly repulsive to him that he sprang up out of his chair, declaring that such talk as that was so disgusting to him that he could not stand it. His actions and words said, "We will not have this man to reign over us." I have noticed other incidents, showing that, where the heart is steeped in sin, and where one is guilty of crime, the words of Christ arouse almost to a frenzy. The disposition seems to be just about the same as the world showed at his crucifixion. Now, do not be disheartened, dear friends. Christ's kingdom is making great strides. The conflict with evil, during the centuries that are past, has been a long and fierce conflict. But that meek spirit is beginning to prevail. When Jesus said, "Blessed are the meek, for they shall inherit the earth," he did not tell us that long centuries must pass before the fulfillment of the prophecy; but he knew it, nevertheless.

Now, do you not agree with me, that it is not whisky, nor even dramshops? It is not bad companions; it is not impure books, even, nor is it altogether owing to childhood's teachings; but it is the attitude of the heart. Is it not the *choice* that every human being makes, when the matter comes fully and fairly before him? First he says in his heart, and then in his actions, "We will not have this man to reign over us," and then come all these other dire evils. After having said this, he is ready for tobacco; he is ready for intoxicants; he is ready to take hold of an impure book, to open it and look upon its pages; he is ready for Satan, and whatever Satan may bring. On the other hand, if he chooses Christ and him crucified, and says, in thought and act, "*Get thee behind me, Satan,*" how can any of these things harm him? In that attitude he never once contemplates such a thing as touching tobacco or whisky. The bad book would be destroyed before his eyes had even glanced at the evil engravings in it, had he the power to destroy it; and if a pure-minded young man or woman is ever excusable for an act of rudeness, I think either of them would be excusable for destroying a book that is positively bad, no matter how they got possession of it, or who is the owner. One of the girls in my employ once snatched a whisky-bottle from a young man, and threw it out of the window while they were riding in a railroad car. He was partially intoxicated, and was making himself very obnoxious. Do not, I pray you, think me oblivious to what is being done by temperance workers and reforms in general. I only wish, in this paper, to call attention to the fact that, with Christ's love in the heart, and a spirit of obedience to him, our boys and girls are safe under all circumstances; but with the other attitude, indicated by our text, they are never safe under *any* circumstances.

Blessed are the pure in heart, for they shall see God.—MATT. 5: 8.

AUNT KATIE HILTON TELLS HOW TO BE OBSERVING.

SOMETHING FOR THE JUVENILES.

DEAR CHILDREN:—How many of you can tell, after you have been in a place, where the most prominent things are? Do you think two of you out of ten could tell me? Now, do you know that is a trait worth cultivating? Suppose I ask Johnny to get the flat-irons. Don't you believe he would say, "Where are they, mamma?" when he had seen where mamma kept them many and many a time? Supposing you hired a boy or girl to work for you, and you took considerable precious time to show her where things were, don't you believe you would think the most of that child who could go and get, or tell where a thing could be got, immediately? Now, I do not believe in having a person, when he is in a strange place, staring at things nor prying into things. Learn to notice, and remember; but do it quietly and quickly.

One dear little girl I used to know used to amuse me very much with that peculiar trait. She was a very quiet child—one that you would least suspect of prying about, and, in fact, I never saw her examining any thing; yet if any thing were lost, or we were wondering where such and such a thing was, she would always say, "I can tell where it is, Aunt," and she generally was correct.

It is very convenient, not only to ourselves, but it is often a great help and pleasure to others. Now, little ones, practice it, and see how well you can do. Some have the faculty of describing dress. I do not advise you to cultivate that trait, for I feel that it leads us wrong sometimes. While looking at dress we are apt to get to criticising, and may be to envying, and we fail to see the person while looking at the dress; but if we quietly examine the person, we can often find something lovely and well worth seeing, even in those who at first sight seem almost beneath our notice. And how nice it is, when we hear some one condemned, to be able to speak a kind word for him! Learn to be bright and observing; and if you can not talk much, you can show by your manner that you are trying to understand.

A friend told Mr. H. an incident the other day that partly illustrates my meaning. He was going on a passenger steamboat from Los Angeles north. One day the fog settled down early after noon, and was so thick that nothing could be seen to guide the ship by, so she was run on "dead reckoning"—that is, they knew about how many miles the boat could go in an hour, in her usual track. About four o'clock Mr. P. said to the captain, "Captain, I wish you could put me off here."

"Why, where do you suppose we are?"

"Just off Point Sal."

The captain laughed.

"Why, friend, we are nearer Port Harford, about 30 miles further north than Point Sal."

Mr. P. could not quite believe it. His home was at Point Sal, and he had noticed the sound of the waves until he felt that he knew them, and so he stood at the bow of the boat, looking and longing to see the familiar shore where his loved ones were, from whom he had been separated so long. While still trying to see, he heard the waves striking on Seal Rock, or thought he did—a large rock that stands out in deep water quite a bit from shore. He felt so sure that he redoubled his watchfulness, and

soon there loomed up, close to the bow of the boat, a monstrous rock. The captain had also come to the bow of the boat, and Mr. P., with a strong exclamation, called to the captain, and told him there was Seal Rock.

"Hard a-starboard!" screamed the captain; and the boat, quickly turning, just missed going upon that rock, where in all probability she would have been broken up, and may be many lives lost.

Los Alamos, Cal.

AUNT KATIE.

Aunt Katie, I thank you for the little lesson you have given us. You will notice that I have something to say on this same trait, in the Home Papers this month. Using our eyes and ears, and training them to be faithful servants, is a wonderful help to any one who wants to be helpful to his fellow-man. In the incident above, this man's remarkable powers of observation, with ears as well as eyes, saved the ship, and the crew with it, from, possibly, a watery grave.

CARP IN FAR-AWAY CHINA.

SOMETHING ABOUT HEATHEN WORSHIP AND SUPERSTITION THERE.

ABOUT six miles from the city of Foochow is a mountain called Ku-shan, or Drum Mountain, which rises directly from the plain to the height of 2903 feet. Half way up the southern slope is situated a Buddhist monastery, covering two or three acres of ground. Embowered in trees, and watered from the mountain above, it constitutes a delightful summer resort. When the long-continued heat of the plain below begins to tell on us thin-skinned Americans, a little money can secure us a rest here, even if we do eat beef, kill vermin, and commit other such enormities. There are about one hundred and fifty Buddhist priests connected with the establishment. Of idols, large and small, there are perhaps three hundred. The largest of them are three, called the "Three Precious Ones." They are each about twenty feet high, and are made of wooden frames plastered over with clay, and then overlaid with goldleaf. They sit side by side in the main temple, cross-legged, each on the figure of a gigantic lotus flower, and their faces wear the most perfect expression of dreamy repose. Public worship is held in their presence twice every day. About half-past three in the morning, the priests, to the number of sixty or seventy, are summoned from their couches by the beating of a fish-drum. This is the trunk of a camphorwood-tree, carved in the form of a fish, and hollowed out so as to resound. They spend about an hour in worshipping Buddha. The worship consists of repeating over and over, in various strains and postures, the words, "Aw-me-taw-huk," which is the Chinese form of *Amida Buddha*. A part of the time they are standing, a part of the time kneeling, and another part of the time, marching about. Bells, large and small, and curious wooden drums of various sizes, are by turns tolled and beaten to keep time. The same thing is repeated about 4 p. m. The end and aim of all they do is to make merit for themselves, or others who pay them for it.

Connected with this monastery is a large fish-pond in which are kept a number of fine carp as a work of merit. Any one wishing a share in the

merit buys small hard biscuits of the priest in charge, and throws them to the fish. It is fine sport to see the great fat fellows splashing, pushing, and crowding in the water, trying to suck in the biscuit. The priests consider it a sin to harm even the smallest living thing.

One stormy day several of us were sitting in one of the temple buildings, near the back side of the premises, reading aloud from a book, when we were interrupted by a sudden outcry. One of the priests had just encountered a good-sized snake, which the storm had driven in. Of course, he could not think of killing it, so, loudly shouting, "Aw-me-taw-huk," he seized a broom and a dustpan, shaped like the toe of an immense shoe with a handle to it, swept the snake into this, and, keeping it there by occasional pushes with the broom, he carried it about one hundred yards to the front entrance, and threw it out. The snake attempted to crawl back two or three times, but was thrown further and further, each time, till it gave up and went elsewhere for shelter.

Some of the priests are fine-looking men, but most of them are quite ordinary. Many of them seem sincere and earnest. But one of the worst things about idolatry is, that a man may be very devout and sincere in it, and still remain a rascal. But no one can be a sincere Christian, and not be a good man.

J. E. WALKER.

Foochow, China, Sept. 1, 1885.

Many thanks, friend Walker, for your very interesting letter, especially that part relating to the carp. Perhaps I might inform our readers, that we have just now a little greenhouse, 19 x 24 feet; and in the center of the building, under the large central bed, is a tank, or cistern, open on all sides, where we have a dozen or more carp swimming about as happy in the warm sunshine as ever carp were in the open air, for aught we can see, and we hope to see how large they will grow by next spring. We think a great deal of the carp, like your Chinese friends; but if a rattlesnake should invade our greenhouse, I don't think he would get a chance to crawl back many times.

A GOOD REPORT: 157 LBS. OF HONEY PER COLONY.

HONEY TO BE NAMED, ETC.

ISEND you by to-day's express a sample of extracted honey; and to settle a dispute, I want you to decide the kind of flowers it was gathered from. I have 2000 lbs. like the sample yet, and 1200 lbs. of candied honey. Extracting 6000 lbs. of honey I got less than 12 lbs. of wax from cappings and broken combs. I think you will conclude it is good enough, if it was taken before it was capped over. I keep it in barrels, and the sample hasn't begun to candy yet. It may commence, though, since I put it in the bucket. What is such honey worth?

I am now fixing my bees for winter, by contracting the brood-nest from 6 to 3 combs, most of them on 6 combs, with 35 lbs. of honey. I took the bee-bread away, but the bees were bringing in pollen yesterday fast. I have fed 500 lbs. of granulated sugar to finish out the combs. I will pack leaves around all my bees, and winter on summer stands. I wintered them all that way last winter—43 colonies. I had a

colony on the scales that gathered 31 lbs. in one day, and 148 lbs. in seven days, from English clover, and my whole apiary averaged 157 lbs. per colony, spring count. I took 5 barrels of nearly pure red-clover honey in June, from which I skimmed over 50 lbs. of pollen with the Muth honey-knife. Every few days I would skim it again, and more would rise.

Marion, Ind., Oct. 26, 1885.

B. T. BALDWIN.

Friend B., I should say that the sample you send is clover honey, without question, and it may be from red clover; still it is not ripe enough to bring a good price in the market. If I were you I would let it be in the hives until it is all ripened over, if it does not get thicker than this. We have been paying at the rate of 7 cts. per lb. for good thick clover honey; but I don't believe we could sell honey like your sample, unless it was ripened in some way to make it thicker. Some of the friends who are used to that kind of work can tell what the expense and loss in weight would be, better than we can.

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

A. I. ROOT,
EDITOR AND PUBLISHER,
MEDINA, O.

TERMS: \$1.00 PER YEAR, POSTPAID.

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, NOV. 15, 1885.

He saved others; himself he can not save —MATT. 27. 42.

DISCOUNTS FOR ORDERING GOODS NOW, FOR
NEXT SEASON'S USE.

OUR discount of 5 per cent on goods ordered now for next season's use will be continued until Dec. 1. Please mention it when you make an order. This is in addition to all other discounts.

PHOTOGRAPH OF THE MEMBERS OF THE BEE-KEEPERS' CONGRESS, TAKEN AT NEW ORLEANS.

We have not as yet been able to obtain the names of all shown in the picture; but the fact that it contains good photographs of the noted bee-keepers enumerated on page 599 of our September number, ought to make it worth a dollar to any one conversant with the bee literature of the past ten years. We can mail it at the above price.

HUMBUGS AND SWINDLES.

ONE of our subscribers sends us a new circular from Mrs. Cotton, in regard to her pure-blood Italian bees at \$20.00 a colony, and the same old story in regard to her book with drawings, illustrations, etc., for \$4.00. He adds, as a postscript, at the bottom of the circular, the following:

She caught me once—can't catch me again.
Blackstone, Mass., Nov. 10, 1885.

J. HERVEY.

W. Z. HUTCHINSON'S 6-CENT SHIPPING-CASE.

SOME of the friends seem to have got the opinion that these cases could be made to order to hold any size of section, for the above very low price, but this is impossible. The only way they can be made

for 6 cts. is by making a great lot of them at once, and you know we can not do this for odd sizes. A friend just now sends us an order for four, to hold an odd-sized section. For such an order we should have to charge about ten cents, and I doubt if it would pay expenses, even then.

STANLEY'S AUTOMATIC HONEY-EXTRACTOR.

OUR friends will notice that the reports we called for in regard to these machines have all been remarkably favorable; and judging from the machine submitted to us for inspection, I should say that G. W. Stanley & Bro., of Wyoming, N. Y., have the best machine for reversing the combs by simply reversing the motion, that has ever been brought before the public. They make them for reversing frames from two in number up to ten, and the price is from \$12.00 to \$58.00, according to the size and number of frames. They furnish circulars on application.

WIRED COMBS; THEIR ADVANTAGES.

AFTER the mishap mentioned on our first page, it was found that not a comb had been broken from the frames in any of the six hives; but had these combs not been wired, the damage would have been fearful. The shock was so great that some of the sticks composing the frames were broken; but these can be replaced with but little trouble. The wires held the combs together, so that but little if any honey was started to running. Some bees were mashed, but no queens were killed. The accident was caused by a slip of the foot of the driver, who was unloading manure. It had been raining a little, and the bed of the wagon-box was—well, you know how. When she started he grasped for the lines, but his foot slipped, and—remember the moral.

ADVANCE IN CUT NAILS.

A GREAT many goods are a good deal lower once more, as you will see by our new price list, 50th edition, sent on application. The American watch, that has been so many years \$10.00, is now \$9.00, and better made than ever before—incaised in 2½-ounce coin-silver case, manufactured by the American Watch Co. themselves. While so many things are down, nails are having a boom upward, caused by strikes among the nail-makers. Instead of the prices in our list, read—8d nails, 5 cts.; 6d common nails, 5½ cts.; 4d casing, 6 cts.; 4d common nails, 6 cts.; 4d casing, 6½ cts.; 2d fine, 9 cts. Prices by the whole keg of 100 lbs., a little lower. No advance on wire nails at present writing.

BEEES AND GRAPES.

ALTHOUGH the suit concerning the bees and sheep has terminated so happily, not so with the California suit by one of the grape-growers. The jury gave a verdict against the bee-keeper for \$75.00 and costs of suit, which amounted to over \$60.00. Now, it is my opinion, as perhaps many of you know, that bees are sometimes annoying to grape-growers, even if they do not puncture sound grapes; but whether the annoyance is sufficient to warrant grape-growers in commencing prosecution in general against bee-keepers, we presume will have to be determined by the courts. At any rate, we bee-keepers ought to be fairly represented in the matter. To that end, I would advise all, who have not already done so, to send their one dollar to the editor of the *A. B. J.*, that they may become members of the Bee-keepers' Union. For further particulars, see *A. B. J.* for Nov. 11.

FOREIGN BEE JOURNALS.

WE not only receive and keep on file all the bee-journals published in the English language, but we have most if not all published in foreign languages. Our friend Jacob, of whom I have often told you, reads German, and Mr. W. P. Root, our shorthand writer, reads French and Spanish; and while we are about it, our friends of the *Bulletin d'Apiculture* have given our price list such a very kind notice that we take pleasure in reproducing it below.

Among the catalogues which we receive, the following deserve special mention: That of A. I. Root, Medina, Ohio, Editor of *GLEANINGS*, and the largest manufacturer of apicultural articles in the entire world, contains 40 large pages, with several hundred engravings, and in it one finds enumerated every thing of which a bee-keeper has need—hives, bees, extractors, smokers, cans, instruments, and accessories of all kinds; foundation-machines, scales, circular saws, steam-engines, carpenter tools, seeds of plants, and even watches.

Of course, I am not able to read the journals in other languages; but our stenographer runs them over; and when he finds points of interest my attention is called to the fact, and I always "look at the pictures" and I feel a great pleasure in looking over these periodicals in other languages, even though I can not read them.

QUEENS DURING THE WINTER MONTHS; WHO SHALL FURNISH THEM?

ALTHOUGH we have been in the habit for many years back of mailing queens almost every month in the year, we have decided that it does not pay us nor our customers to continue the business, say after Dec. 1; but where you *must* have a queen after that date, I would suggest that you by all means get them from friends in the South. Some enterprising queen-breeder in the Southern States can easily prepare himself to ship queens any month in the year, to any one who may have need of a queen. Now, to save a good deal of useless correspondence, will not some of our Southern friends announce their readiness to furnish queens all winter? They can be shipped to us, it is true, and we could re-ship them; but this seems to me an expensive and foolish piece of business. During the past winter we had orders from the Southern States for queens during the month of January. Well, to fill such orders we have many times sent queens that had just come to us from the South. The poor little creatures were obliged to take a trip of over a thousand miles into a Northern climate, and then go straight back to pretty near where they originally started from, just because folks preferred to send to us, rather than to neighbors not very far off. We will give the names of those who are prepared to send out untested queens on receipt of orders, from now until Jan. 1, free of charge, provided you who send in your names have the queens all ready to mail. Of course, we want the names of men who are known to be in good standing.

THE SHIPMAN STEAM-ENGINE.

WE have just received one of the above engines, in order to give it a trial, to see how it would answer for bee-keepers, for hive-making, etc. Only two sizes are made—one and two horse-power; prices, \$125 and \$200 respectively. The engine uses a cheap grade of coal oil, instead of coal. Now, it is a fact that coal oil is more expensive for fuel than coal; but to offset this it is made so automatic that it works without an engineer, and an engineer usually costs more than coal. Again, the engine itself turns on the oil in proportion to the work to be done. If you require a whole horse-power, the machine itself turns on the oil accordingly; but the

minute you throw off the machine, and ask it to do something requiring only the power of a child, the oil begins to be cut down so as to consume that amount and no more. It takes what water it needs, in just the same way; and in case of any accident of any kind, such as water getting out of the boiler, too much water coming in, or too high pressure, it blows itself out and cools off. For instance, you can set the limit of the steam-gauge at any point you wish, according to the work to be done; that is, if you do not wish the pressure to go above 100 lbs., the machine itself cuts off the fuel when it reaches that point. It seems as if it were impossible for it to explode or do any harm. The machines are very extensively in use for running printing-presses, and such like work, and it seems as if they ought to be worth what they cost, almost anywhere. Of course, if a bee-keeper expects his business to grow, he wants a larger engine than one-horse—may be even more than two-horse; but to those who have been in the habit of running a saw by foot power or hand power, these little engines would, in a very short time, earn the \$125. You can have them shipped promptly to any address. They are so light that the shipping is but little. You will notice, that the two-horse-power engine costs a little more than the two-horse power engines we have been selling, and advertising in our price list.

PANSIES.

A BEE-KEEPER IN TROUBLE, AND HOW WE MAY HELP HIM OUT.

I LOST my bees, and it left me flat on my back, as I had put all I had into them; and now as GLEANINGS and bees have got me into trouble, it seems but just that they should help me out again. I will tell you how. This summer, from May 1st until now, I have had a large bed of splendid new improved, fancy, large flowering, German pansies (the very choicest known), that have been in constant bloom, the wonder and admiration of all, averaging from 90 to 200 flowers in bloom upon a single plant at a time, flowers from 2 inches across upward, and of a hundred different colors, and marking all rich and velvety. The bed will bloom until snow. I have thousands of fine young plants from above bed, and I will send by mail 10 or more plants (mixed) to any one for 1 cent each (never sold for less than 5 cts. each). These plants will bloom from very early in the spring until snow next year.

I lost none in wintering out of doors last winter, or in transplanting. I send you a few flowers cut from above bed. Throw them into the coldest water you have until freshened up. I have 2 swarms of bees—1 Italian, 1 hybrid; they are doing well. Who has a good Italian queen to exchange for pansy plants?

F. V. SARGENT.

Hubbardston, Worcester, Co., Mass.

Friend S., as a rule we do not admit advertisements in this way; but when you offer those large pansies for only a cent each, it seems to me we may please our readers, and help you too, by making public your offer. If they will blossom this winter in our greenhouse, you may send me 500 to start with. The samples you send are certainly very handsome.

DADANT'S FOUNDATION

is asserted by hundreds of practical and disinterested bee-keepers to be the cleanest, brightest, quickest accepted by bees, least apt to sag, most regular in color, evenest, and neatest, of any that is made.

It is kept for sale by Messrs. A. H. Newman, Chicago, Ill.; C. F. Muth, Cincinnati, O.; Jas. Heddon, Dowagiac, Mich.; F. L. Dougherty, Indianapolis, Ind.; Chas. H. Green, Berlin, Wis.; Chas. Hertel, Jr., Freeburg, Ill.; Ezra Baer, Dixon, Lee Co., Ill.; E. S. Armstrong, Jerseyville, Illinois; Arthur Todd, Germantown, Philadelphia, Pa.; E. Kretschmer, Coburg, Iowa; Elbert F. Smith, Smyrna, N. Y.; C. T. Dale, Mortonsville, Ky.; Clark Johnson & Son, Covington, Ky.; King, Aspinwall & Co., 16 Thomas St., New York City, C. A. Graves, Birmingham, O.; M. J. Dickason, Hiawatha, Kan.; J. W. Porter, Charlottesville, Albemarle Co., Va.; E. R. Newcomb, Pleasant Valley, Dutchess Co., N. Y., and numerous other dealers.

Write for samples free, and price list of supplies, accompanied with 150 complimentary and unsolicited testimonials, from as many bee-keepers, in 1883. We guarantee every inch of our foundation equal to sample in every respect.

THE CANADIAN BEE JOURNAL.

WEEKLY, \$1.00 PER YEAR.

D. A. Jones & Co., Publishers, Beeton, Ont., Can.

The only bee journal printed in Canada, and containing much valuable and interesting matter each week from the pens of leading Canadian and United States bee-keepers. Sample copy sent free on receipt of address. Printed on nice toned paper, and in a nice shape for binding, making in one year a volume of 832 pages.

HONEY AND BEESWAX.

We are now in the market, and will be during the entire season, for all honey offered us, in any quantity, shape, or condition, just so it is pure. We will sell on commission, charging 5 per cent; or if a sample is sent us, we will make the best cash offer the general market will afford. We will handle beeswax the same way, and can furnish bee-men in quantities, crude or refined, at lowest market prices. Our junior member in this department, Mr. Jerome Twine, has full charge, which insures prompt and careful attention in all its details.

Sample of comb honey must be a full case, representing a fair average of the lot. On such sample we will make prompt returns, whether we buy or not.

NOTES FROM THE BANNER APIARY.

NO. 72.

BURYING BEES.

J. B. WHITAKER, on page 753, asks about burying bees. If I had no cellar in which to put bees, I think I should bury them. If a cellar can be kept at a proper temperature, I see no advantage in burying bees, over cellar wintering; while the burying of bees and the "unburying" of them, especially the "slicking up" afterward, is not the most agreeable kind of work imaginable. The plan mentioned by Mr. W. is all right, only be certain that they are buried deep enough so that frost will not enter. The few colonies that I put in a clamp last fall wintered the most perfectly of any colonies that I had.

QUEEN-EXCLUDING HONEY-BOARDS.

I first made the Heddon honey-board to be queen-excluding, in the way mentioned by Geo. F. Williams, page 740; but the trouble was in adjusting the slats and keeping them adjusted; and it was when talking the matter over with R. L. Taylor that he suggested using a saw of exactly the right thickness for cutting slots in a thin board, thus doing away with the adjustment of slats; and, if the bees would not fill up these slots in the board, I would ask for nothing better. It is possible that this trouble may yet be remedied; if it isn't, we shall have to clean out the wax once a year, or else use zinc. It is the

HEDDON SHIPPING-CRATE,

not the "Hutchinson," that I am selling in the flat at 6 cts.; and were it not that I can get the lumber very cheaply I could not furnish them for that

price. To those who have written, asking for the privilege of manufacturing, I would say, apply to Mr. Heddon. It is another one of the many good things he has given us. It is amusing, sometimes, to hear dealers, and even bee-keepers, ask, "How many of those cases do you put into a crate?" The idea! Put the neat, easily handled cases into a big crate or box, so that the railroad men can roll them over and over, and "dump" them? No, never! If one is not enough for a load, a man can take two or three, or even four, just according to his strength or inclination.

EXPERIMENTS IN WINTERING.

We have been selling and trading off, and uniting our bees, until we have only 50 colonies left. Some of these have sugar stores and no pollen, or bee-bread, in the combs; some have sugar stores with a little bee-bread in the combs, others have sugar stores with combs fairly loaded with bee-bread. Some were undisturbed with their natural stores, while others have both sugar and honey. Those that we have sold had this same variety of stores, and the hives were marked with the kind of stores. We shall put nearly if not all of our bees in the cellar under our house.

8—W. Z. HUTCHINSON, 77—30.

Rogersville, Mich., Nov. 25, 1885.

Friend H., I am very glad indeed to hear you say that a cellar can be made to answer as well as the clamps. Clamps are certainly a deal of trouble, and the general untidiness about them is enough of itself to discourage me from recommending any such system. The six-cent shipping-crates are nothing particularly new, except they are made to hold a small number of sections, and are so

arranged that they can be made very cheaply. We will try to have an engraving of them made for our next issue. We shall be glad of a report of the result of your experiments in wintering.

SOLAR WAX-EXTRACTORS.

ALSO SOMETHING ABOUT POISONOUS HONEY.

THE subject of solar wax extractors has excited considerable attention among bee-keepers during the past year or two. Everybody who has tried one seems enthusiastic over them. I made myself one last August while I was waiting for that honey to come that never got here, and I would not want to do without it for several times its cost. We had very little hot weather after I got it finished, but it worked to a charm, and proved to me beyond doubt, that, during ordinary summer weather, wax can be made by it with far less time, worry, and muss, than by ordinary means; and, what is more, the wax made is of the finest and most uniform quality, and there is not the slightest danger of scorching or otherwise spoiling it in the making. Moreover, when making wax from cappings (which was my principal purpose in making mine), a large amount of honey is saved that would be wasted by most other methods.

My extractor consists of a V-shaped tin trough, 20×24, and 8 inches deep, eased in a wooden box. To the top of this box is hinged a sash, holding two sheets of glass, each the whole size of the top, separated by a ¼-inch space. Over the whole is hinged a cover, which is lined with bright tin; and a light board, 20×24, is also covered on one side with bright tin. These tin surfaces are for reflectors.

The comb to be melted is placed on a sheet of perforated zinc resting on the sides of the trough, about 3 inches below the glass. When in use, the cover is raised at right angles to the glass, and held in that position by the reflector-board, which is provided with hooks for that purpose, and is placed in the angle between sash and cover. In the morning it is placed on the west side, and at noon changed to the east side. When the extractor is not in use, this board is laid on top of the sash, and the cover closed down over it. You will see that there is a large reflecting surface throwing heat into the extractor, besides that given by the direct rays of the sun, while the double glass retains this heat. Before using the reflectors I found that, on a warm day, a thermometer inside registered 60° higher than one outside; and after I put them on I noticed a temperature of 210° inside one day. We shall probably use it to bake bread, roast meat, etc., next summer. You may be sure that such a temperature melts down the comb very fast. Several lots can be melted down in the course of a day. The wax and honey drip down through the perforated zinc, below which there is considerable space. When the weather is not hot, the wax does not form in a solid cake, as it is shaded by the zinc. When the lower part is full, take out the zinc, when the wax can be easily melted, and, if desired, kept in a melted condition all day without disturbance, thus perfectly purifying the wax. The honey is drawn off through a tube in the bottom. I am satisfied that a single thickness of glass will answer, although it should be large enough to cover the

whole top, as the shadow made by a cross-bar would prevent the melting of a part of the comb. It would be best to have the reflectors of cheap looking-glass, instead of tin, as tin will soon tarnish and rust.

You say, on page 775, that it seems to you astonishing that the heat of the sun alone should melt beeswax. Did you never notice that a piece of wax, laid on top of a hive, especially if dark colored, on a hot day would very soon melt and run? A large part of the heat of sunshine is latent, and we must imprison it and change it to sensible heat, to be aware of even a part of the tremendous power concealed in a sunbeam.

POISONOUS HONEY.

The subject of poisonous honey, which has attracted some discussion lately, is of somewhat more importance to the bee-keeper than it may seem at first thought. The bee-keeper needs to understand the subject thoroughly, in order that he may be able to successfully combat popular prejudice. That such prejudice often exists, is undoubted. Many are of the opinion that certain kinds of honey are poisonous. Others think there are some persons to whom all honey is poisonous. Many are inclined to place great credence in newspaper accounts of poisonous honey, and refrain from the use of all honey in consequence.

By the way, it is a little curious the way the non-bee-keeping public regard and treat our industry. Five hundred deaths from any one of the numberless common accidents of life would hardly cause as much newspaper comment as a single death from a bee-sting. I believe it is a fact, that people are more easily prejudiced against bee-keeping than almost any other occupation. People have been dosed so often with newspaper articles in regard to the adulteration and poisonous qualities of sugar, syrup, canned fruits, etc., that they are quite accustomed to the idea that all such things are adulterated, and more or less unhealthy; yet their purchases of these articles are little or not at all influenced thereby. But when honey is to be considered, it is entirely different. The least hint of adulteration scares off the would-be purchaser. The paraffine-glucose-comb-honey story is not only believed, but acted upon. Dealers have told me that they could sell honey in large, old-style boxes, with their crooked, irregular combs, better than our nice, white, straight section honey, because their customers believed the latter was manufactured.

"The bees *could* not make every box just alike, and straight as a board." A St. Louis man told me it was impossible to buy pure honey of any kind in that city, and that he had bought comb honey which was made of *paper*, and filled with glucose.

So every widely spread and apparently well-authenticated report of honey-poisoning may work great injury to our honey interests. Every traditional idea in regard to the unwholesomeness of honey may do us harm. Let us, then, get at all the facts in the case, so that every intelligent bee-keeper may have arguments at hand to refute erroneous statements. The articles we have had on the subject, especially those by Dr. Higbie and Prof. Cook, have been very satisfactory, and I think have effectually disposed of the subject as far as they have entered into it; but there is another point that I think may have some value. Dr. Higbie is on the right track in the last part of

his article, although his information has probably got a little twisted. I believe honey is sometimes, to a certain degree, poisoned by the poison of the bee-sting. This is not caused by the bees stinging the honey-comb, certainly not by the stings left behind; for, as Prof. Cook says, even if the bees did sting the comb, the stings would not be left behind.

It is quite possible, that honey may become poisoned through the crushing of bees. I think, though, that this may more often come about from the poison *wiped off* from the protruded stings of angry bees. Who, on opening a hive on a cool morning, has not noticed the rows of upturned stings, each with its drop of poison on the tip? What becomes of this poison? It is very unlikely that it is reabsorbed by the poison-sac. I am familiar with the taste of this poison. I have often tasted it upon my hand, left there by a bee that had not stung me. I have also detected it on the surface of sealed honey by touching it with my tongue shortly after such a display of stings as I have mentioned. Now, I think here is at least one reason why some people can never eat honey; why others are unpleasantly affected by any thing more than the smallest portion, and why a large quantity sometimes produces such severe results.

Let me give some facts in support of this. People have frequently told me that comb honey "did not agree with them," while they could eat extracted honey with impunity. It is easy to see that the poison, being on the surface, would be cut off with the cappings, and ordinarily would not get into extracted honey. Other persons can not eat even extracted honey until it has first been boiled, after which they can eat it freely. In this case, the poison, being volatile, is boiled out of the honey. Again, it seems that honey which has been kept away from the hive for some time may be eaten more safely than the same honey, even when well ripened, when just taken from the hive. Here the poison has evaporated, through the lapse of time.

I do not mean to say that all honey contains this poison. Probably that taken by the skillful apiarist during the honey-flow, when bees are good-natured, does not contain a trace of it. But a great deal of honey is taken at such times, and under such circumstances, that it might easily contain appreciable quantities. Have you not heard some old bee-keeper tell how, without smoker, but with bee-hat and buckskin gloves, with trousers in boots, and sleeves tied down, he sallied forth to "rob his bees"? how the bees covered those gloves with stings until you could hardly put a pinhead on a spot without a sting, and how the air was fairly reeking with the venom of the infuriated insects? Is it not possible, that in such a case a considerable amount of venom is deposited on the comb? Suppose a bee-tree is taken under such circumstances, and the venom of crushed bees added to this amount.

Right here there is a difference between "wild bees" and "tame bees," although, of course, the bees in the forest are no more *wild* bees than are those in the box hives out in the orchard, which the owner never goes near, except at "swarming time" or "robbing time." Gentle bees, accustomed to handling and human companionship, and properly handled, do not get into such frenzies as I have described, while "wild bees" do sometimes, when gone at rough-shod at improper times.

I have never heard of a single case of sickness arising from honey sold by me; but my customers have frequently told me how often they used to be made sick by honey taken in the old-fashioned way.

J. A. GREEN.

Dayton, Ill., Nov. 18, 1885.

Friend G., we are very much obliged indeed for your report in regard to the solar wax-extractor, and it begins now to be plain to me that we shall have to add another implement to our list of supplies; and that we may be able to offer the best possible solar wax-extractor, I would ask you to make one just as you would have it, without regard to the time and pains it may take you, and then to forward it to us by freight or express, as you deem proper, with a bill for all your trouble and bother. I want to ask if you have tried the machine with two sheets of glass and one sheet of glass. If you have, and if two sheets are an advantage, why not make the machine with an air-space on all sides, so as to confine the heat? The east, west, and south sides should have an outer covering of a sheet of glass, while the north side and the bottom may be protected by an extra thickness of sound lumber, so as to make a dead-air space between the two. We shall probably have to make the machines of at least two prices—one having cheap looking-glass plates for reflectors, and the other having reflectors of tin. The tin reflectors cost so little they can be replaced for a small amount. Just now, however, a cheap grade of looking-glasses may be had for a very small sum. There will be one objection to shipping a machine taking glasses as large as 20 x 24, because of the risk of breakage on sheets of glass so large. Any other important facts in regard to manufacturing these machines for sale we shall be very glad of, and will willingly pay for. I did feel a little astonished at the reports of wax melted by the sun alone; but by the use of mirrors we may get almost any desired temperature. In our philosophies there is record of a machine made with several hundred small mirrors placed so as to throw their reflection on a single spot, that would melt and burn the most refractory substances.—In regard to poisonous honey, I think you are right. The matter was some time ago suggested, that the venom from bee-stings might make the honey deleterious to people very sensitive to bee-poison. I think Mr. Langstroth called attention to it.

HAULING BEES.

WHAT TO DO WHEN A HORSE IS STUNG.

IN increasing my business beyond that point at which I could keep all my bees in the home apiary, one of the greatest difficulties in the way was the matter of hauling. To sit on a load of bees, in momentary fear lest the bees should find their way out, and make a raid on your team, is any thing but soothing to the nerves. In more than one instance I had to jump from my seat, and, with all possible dispatch, unhitch the horse or horses, and take them some distance from the wagon till I could make every thing secure. By the way, it has been a matter of importance, several times, for me to know what to do with a

horse when attacked by bees. In all cases that have come under my notice, the attack has been about the head; and the first impulse of the horse always seemed to be to get to some place where he could rub his head. Latterly, when trouble occurs I spring to the horse's head and commence rubbing it all over with both hands and arms, and he seems satisfied with that, without showing any desire to run. I do not know whether other horses would act just the same in all cases, but it might be worth while to try.

Of first importance is the matter of fastening the bees in the hive. If you have never had any experience in the matter, you will be surprised to find how difficult it is to shut up a number of hives so that no single bee shall be able to get out, on a journey. There must be no half-way work about it; you must be absolutely certain that every spot is tight—bottom, top, and sides. In hot weather, as when moving to get the benefit of a buckwheat field, abundant ventilation must be provided. For this purpose I have replaced the cover of the hive with a frame 3 or 4 inches deep, the entire top of which is of wire cloth. The quilt is entirely removed, and the entrance closed with wire cloth, and in this way I have safely taken them in the middle of a hot day. Generally, however, I haul them in spring and fall (to the out apiary and back again), when not so much ventilation is needed. No ventilation is given, except through the entrance of the hive. The bees are confined to the hive by a stopper made thus: A strip of wood one inch wide, $\frac{3}{4}$ inch thick, and as long as the entrance of the hive is wide; a strip of wire cloth about $2\frac{1}{2}$ inches wide, and as long as the stick already described. Fold the wire cloth double, making a double strip $1\frac{1}{4}$ inches wide, and as long as the stick. Nail the wire cloth on the flat side of the stick, letting the folded side of the wire cloth project $\frac{1}{2}$ inch. The double-pointed tacks lately figured in GLEANINGS are very nice for this purpose. Place the stopper over the entrance, and drive into the stick an inch or two from each end a $1\frac{1}{2}$ -inch wire nail, leaving $\frac{1}{2}$ inch or more of the nail projecting, so that it may be easily withdrawn with a claw-hammer. After these have been used some time, the nail-holes become so large that it is necessary to bend each nail after driving, in order to hold the stopper tight up to the hive.

To make the top of the hive doubly secure, I use a square of cotton cloth 6 or 8 inches larger each way than the top of the hive. Spread this cloth over the top of the hive, letting it project on each side, then put on the cover. If there is no wind this makes all secure; but if windy, the cover must be fastened on by means of pieces of leather or cotton cloth 2 or 3 inches long. Drive a large tack through one end of the leather into the body of the hive, and another tack through the other end into the cover. Let the cover be thus fastened at two opposite sides or corners. As the covers of my hives rest on cleats, I find it quicker to tie them on with stout twine, running the twine under each end cleat, and crossing it in the form of an X on top. I never fasten the frames in the hive in any way, but I never clean the propolis out of the hives in the spring till after hauling. I once had some combs break down when hauling in buckwheat harvest. They were new, not wired, filled with brood in the lower part, the upper cells empty, and not drawn out. With wired or old combs I have no

fear. If I were shipping on the cars, I think I would fasten the frames in the hive.

I had always supposed it necessary to have a bed of hay, or a spring wagon, to save combs breaking down, until Mr. Von Dorn, of Omaha, told me he used a hay-rack on a common wagon, without hay or springs, and I have since carried them safely the same way. Simply nail narrow strips across the rack, and put little blocks at the proper places, so that each hive will be kept in its own place. A common hay-rack will hold about 20 ten-frame Langstroth hives. As I keep only one horse I usually haul my bees on a one-horse wagon, having a light rack made to set over the wagon-box. In this I can haul 11 hives at a load—3 in the box, and 8 on the rack.

To provide against accident it is well to have hammer, nails, and lighted smoker on the way. Over any rough piece of road I drive very carefully; but on nice, smooth road, I sometimes strike a trot.

I like to unstop the hives as soon as they are unloaded. It is most easily done by using a little smoke, although by moving very slowly it can be done without. C. C. MILLER, 179-340.

Marengo, Ill., Nov. 23, 1885.

Friend M., although it may be that you have planned to tell it at some other time, I have been very curious all through your article to know how you succeeded in "carting" your bees around. Did it pay, and have you made "a great big lot of money" with your bees this year, the way you have been doing lately? You speak of drawing eleven hives at a load. I suppose that you know that, if you used Simplicity hives with a sheet of wire cloth over both top and bottom, you could take almost twice as many as with the style of hives having cleats and projections and porticos, and caps to slip over, etc. We have a wagon that was made expressly to hold a certain number of Simplicity hives; and, put up in the way in which I mention, they are so light that even one horse will draw a great many safely. The Simplicity hive is so simple that there is not much danger of bees getting out, with a wire-cloth frame over both top and bottom. We make these wire-cloth frames by securely fastening the wire cloth on just such strips as we put under the cover. In fact, we throw out all imperfect strips in making hives. This gives us a great surplus of these pieces of wood. Why, we have had so many that we have sometimes burned them up, even though they were just as good as any for holding wire cloth.—We notice that you have increased from 179 to 340, and we are glad and thankful for this little piece of news. But, tell us about the honey and—MONEY.

OUR OWN APIARY.

SNOW AS A PROTECTION, IN THE ABSENCE OF A WIND-BREAK.

TO-DAY is Thanksgiving, and the snow is from four to five inches deep. Many of the hives are banked up with snow. Some of the empty Simplicity hives are almost covered; for, as a general thing, we leave our summer hives out the year round, and then they are all ready for next season.

OUR EVERGREENS AS A WIND-BREAK.

Our apiary has no wind-break in the way of a tight board fence, such as we had formerly at the old home. There is, however, as you doubtless know, an inclosure of evergreen-trees that, in a few years, will afford us the best of protections. The trees when first planted (1878) were from three to four feet high, and at present date they are all the way from six to eight feet, and several are nearly ten feet high. They do not as yet afford much protection, for the reason that they have not begun to bush out, and, as a consequence, the wind makes its way through, the space between the branches being about two feet. With all the advantages of a wind-break, it seems to me there is at least one advantage in having the hives exposed to the wind. Where we have an abundance of snow, the wind, having free access, banks up the hives much better than if the apiary were protected. Our hives being thus exposed to the wind on three sides—north, west, and south—present quite an array of little pyramids. The space between the hives is thus dished out, and the snow banked just where we want it. But for all this, we would by no means say that a protection is not necessary, for in this locality we do not always have snow when we like it. The importance of a good wind-break can scarcely be overestimated. It is only necessary to refer to the successes in wintering of Cyula Linswik and her sister in their home, surrounded by an immense forest. When there a few years ago, the stillness, occasioned by the absence of wind, impressed itself upon me as remarkable.

RABBITS FOR KEEPING DOWN GRASS AROUND HIVES.

It will be remembered, that something over a year ago we made mention of some rabbits. For the past three months we have had a pair of them in our poultry-yard. The number has now increased to nine, though had it not been for the inroad of a certain cat we should have had twice this number. As Mr. Fradenburg has said, they will keep down the grasses to quite a little extent; and if a good number of them were fenced in an apiary they might do good service in the way of keeping down the grasses around the hives. On the whole, however, I think I should much prefer a lawn-mower, as the rabbits are a little inclined to pick out precious morsels of herbage, while the former does smooth, even work, irrespective of taste.

TINKERING WITH HIVES DURING WINTER.

The general work among the bees has, or ought to have, ceased by this time. Of course, if there should be days when the bees can fly, colonies that have insufficient stores can be fed up. Good colonies, when well packed for winter, ought, as a general rule, to be left entirely alone till spring. I remember one winter, that while working with my microscope I had occasion to get a good many bees for dissection. There was one colony in particular, in the house apiary, from which I took my victims. If I am correct, father was not aware that I was getting bees in this way, though I did not attempt to conceal it. But without any thought that I was endangering the colony, several times during the winter I went there, took a few bees and hastily closed the hive, feeling sure that this slight disturbance could do no harm. The following season showed that this colony was dead, when the rest had wintered comparatively well. Merely opening the hive during cold weather will often break the cluster, and the result of exciting the bees is as I have

said. It must not be inferred, however, that a colony must *never* be opened. We sometimes take a queen from a hive in mid-winter, but the weather is such as to permit it.

PREPARING FOR NEXT SEASON.

During the winter months it is well to consider our plans for next year. Sections and hives must be put together, etc. Many new improvements have been suggested during the past year. It is best for us to re-read and consider, so as to be ready for the coming season. For instance, the favorable reports of the sun wax-extractor will warrant us in giving the matter some attention. Perforated zinc is slowly coming into prominence, and should be further experimented upon. Side storing versus top storing; separators or no separators; the best method of preventing after-swarms; clipping queens' wings, etc., are matters of discussion; and your locality, coupled with personal experience, will largely decide which is best. Put yourself at your wit's end. If you have any new scheme, formulate it ready for practice next year. If you have observed any thing new, let us have it, being careful to report exactly what you *did* see: for, as one writer has said, "Men see one thing, and are apt to infer another." Let there be none of this in our work. E. R. ROOT.

EXTRACTED HONEY.

PUTTING IT UP FOR MARKET; HOW A LARGE DEALER AND HONEY-PRODUCER MANAGES IT.

By to-day's mail I send you a small can of honey, put up in the winter of 1882-3. Its exterior is rather rough, it being the last of my stock of that season, and has been handled a good deal as a sample can by which to sell the stock. Is it candied? I put up a considerable part of my product in this style of can, weighing 1, 2, and 3 lbs. respectively. For convenience and expedition in canning honey, I have a coil of block-tin pipe placed in a steam-chest, one end of the pipe protruding from the top of the steam-chest, and reaching to a tank (holding 3 or 4 bbls.), which is placed directly above the steam-chest. The other end of the pipe protrudes from near the bottom of the steam-chest, and to it is attached a small faucet. Now, when ready to go to canning we turn a jet of steam into the chest, or box, in which the pipe is coiled; turn the stop-cock at the bottom of the tank, or top of pipe, to permit the pipe to fill from the tank, and draw off or fill the cans from the small faucet at the bottom of the steam-chest. The honey in passing through the pipe in the steam-box, is heated; one hand draws off the honey, two tanners solder the cans as they are filled, while a hand takes care of the cans as soldered, and labels them.

How is the tank kept supplied? Why, the above work is done in the basement of a plant on a hill-side; the tank is supplied from a heater just above it, which is fitted in the floor of the upper story. This heater will hold 2 or 3 bbls. of honey. The top of it is even with the top of floor. A zinc plate is placed on the floor beside the heater, a barrel of honey is rolled up to the plate, hoops knocked off one end and the head taken out, then the barrel is turned upside down on the zinc plate, the barrel pried off the honey (my honey is always candied solid at this time of year), and the honey swung, or shoved into the heater. A jet of steam is then thrown about the heater; and as the honey melts it

runs through a pipe in the bottom of the heater to the tank below it, which supplies the steam-chest.

As stated above, the building is on a hillside. On the upper side we drive up to the door and unload the honey on a level from the wagon to the floor of the upper story; on the lower side we load honey from the basement—canned, cased, and ready for shipment, into a wagon, without having to elevate it, the bottom of the wagon and basement floor being on a level. Thus, you see, we do the work expeditiously, accurately (damaging no honey by coming in too close contact with fire), and easily. The tinnerns are never given any extra restings—spells waiting for the candied honey to melt.

We put up about 1500 cans a day, working by daylight. During the past three seasons I have made use of the sun evaporator, for the purpose of more thoroughly curing my crop (I extract all my honey). The honey discharges itself from the extractor into a funnel covered with cheese-cloth. It is then conveyed by a short pipe through the wall of the honey-house, and emptied into the evaporator. When thoroughly cured, a pipe, entering the evaporator in its bottom, conducts the honey back through the wall of the building into the basement, and discharges into a large tank, or other storage vessels. The evaporator is placed on the south side of the honey-house, with tin reflector above it. Where I have not a sun evaporator in my apiary I extract none (except as compelled to do sometimes from brood-combs) until fall, but tier my hives up, 3, 4, 5, and even 6 stories high.

Having some time ago read an account of friend Muth's mode of heating and handling honey, and thinking his plan must be very tedious, where so large a quantity is handled, induced me to give you my plan.

A. CHRISTIE.

Smithland, Iowa, Nov. 16, 1885.

I will explain to our friends, that friend Christie probably sells as much extracted honey in small packages as any other one man, unless it is friend Muth, of Cincinnati. While friend Muth makes glass jars his specialty, friend Christie has a special style of tin can, partly described in the above article. I will explain further, by saying that this can is not unlike the ordinary Jones can, as we have called them, except that a tin cover slips on or off at pleasure; and underneath this tin cover is a second top, made of the thinnest kind of taggers' tin, and it is therefore easily cut open with an ordinary penknife; and after this taggers'-tin cover is cut out and thrown away you have a tin box or pail, as the case may be, with a nice-fitting slip-over cover. Below we give a copy of friend Christie's labels as they read on his one-pound honey-package:

PURE HONEY FROM THE APIARIES OF
AUG. CHRISTIE,
SMITHLAND, - IOWA.

Friend C.'s peculiarity in his method of melting candied honey is this: Instead of running steam through a coiled pipe, he runs the honey through the coiled pipe, and the steam is let into the steam-chest surrounding it. I believe there is an advantage in this, because a lower temperature of steam would melt the honey rapidly, and make it flow freely. The sample received was not candied, and I think it quite likely that honey sealed up in this way, when heated to

about the right temperature, would remain in a liquid state until the can is cut open. Although we may not, many of us, go to the expense of just such an apparatus as the above, there are many hints given in the article that will doubtless be a benefit to many of us.

The following is the contents of a circular label on top of the cover. Perhaps we might add, that friend Christie is our largest customer for honey-labels, from which we judge that he sells immense quantities of honey in this way.

This end of this can is simply a slip cover. To open it, cut the label around the edge of this cover, and pull the cover off; then cut out the soft thin end now under the cover, and you have an open can which you can shut and open at pleasure, while using the honey.

A EULOGY UPON SOME OF OUR PROMINENT BEE-KEEPERS.

Well, now, if I did, in a former song,
If I did in *that* do the lion wrong,
I beg his pardon; I'd rather kneel,
Than to be for him a single meal!
But he stands to-day
In proud array—
His fame is fixed and sure.

Here's Jones and Benton—no noble men,
They're marching in the van;
Bring out your heroes, one by one,
And match them if you can.
They marched through many a burning isle,
And swept the eastern seas,
To furnish man and woman kind
The finest race of bees.

And there is Root—"foremost" this Root,
I ne'er can find a rhyme to suit,
Although I start in wild pursuit:
Yet, where is the man with bee repute,
Or any other, that will dispute
That this is a kind and tender Root?

And, lo! afar in summer sky
I see a banner floating high:
And written there in living light
Are words that give the heart delight:
"If all my customers among,
There's any I have done a wrong,
Then let me know, and I will try
My utmost them to satisfy."
'Tis Hayhurst's banner floating high.

For honesty of purpose, sterling worth,
There beats no heart upon this blooming earth
More true and steadfast—none that I would trust
Sooner than Heddon, for I believe him just.

And there is Cook—an honored name,
That stands full high on the roll of fame.
Whether he's tall across, or long and slim,
I also have a "crow to pick" with him.
I'll tell it to you at some other time,
Either in saddest prose or merry rhyme:
How he, from this "vain world" did almost jolt
Your humble servant, with "his little colt."
But there he is—a paragon of men,
A master of the heart, the ear, the pen.

And Mrs. Axtell—there she stands,
Beloved in this and other lands,
A purer faith—a prouder fame,
"Than gathers round Marengo's name."

Another hundred I could name, and more,
That stand full high in apicultural lore.
There's Mrs. Harrison, and Chaddock too,
Might be a fit example unto you.
Cyula Linswik, in her forest home,
And Nellie also, to my memory come.
These names with tenderness I now recall.

These are a few—only a few—
Photographs I present to you.
Sift them and weigh them, one by one.
Humble and poor they all began,—
With head and hands they worked amain.

San Dieguito, Cal.

J. P. ISRAEL.

A MODEL BEE-KEEPERS' ASSOCIATION.

THE EDITOR OF GLEANINGS IS ASKED TO ANSWER SOME QUESTIONS PROPOUNDED BY THE FAYETTE COUNTY (OHIO) B. K. A.

NINE months ago the bee-keepers of our county organized an association, and up to the present time the readers of your worthy journal, except our own members, are in the dark as to what we have and are doing. We started out last February with a membership of 10, and now number 34. We have monthly meetings, holding them around at the homes of the different members, each taking his basket well filled, and having a regular picnic dinner; and with our wives, sons, and daughters, we have a general good time, socially as well as mentally. If you will allow me a little space, I will refer briefly to our last meeting, which was held at the home of Bro. Lewis Haines, Oct. 22d. The day being bright and beautiful, added much to the enjoyment of the occasion. The time till noon, as is our custom, was occupied in looking at some of the outdoor attractions; namely, his hexagonal apiary of Italian bees in the Root chaff hive; also his machinery for manufacturing bee-keepers' supplies; and last, but not least, his beautiful carp-pond, situated near and fed by a never-failing spring. The day being a little cool, we did not get to see any carp; but Mr. H. assured us they were there all the same.

This brings us up to our bountiful feast, of which we all freely partook. After dinner the meeting was called to order by Vice-President Bay, who gave us a brief but appropriate address. There having been no special work assigned to any member, our question-box was opened, and the following questions read and discussed very interestingly:

What is the best mode of wintering bees?

Is it too late to feed for wintering?

What is the best mode of spring management?

Will bees permit a queen and fertile worker to remain in a hive at the same time, and both raise brood?

How would you Italianize an apiary in the spring, without interfering with your crop of honey?

Are bees rearing brood now? if so, is it best for them to rear brood so late in the season?

Is it best to feed our bees sugar syrup, and sell the product for honey? This last question arose from the fact that our market is being supplied now from Columbus with this kind of honey.

An answer to part or all the questions discussed in our last meeting would be very acceptable.

The foregoing questions being very interestingly discussed, the meeting adjourned to meet at the home of J. H. Ferguson, four miles east of Washington C. H., on the Circleville pike, Nov. 19, 1885.

Bloomington, O.

S. R. MORRIS, Sec.

Friend M., I congratulate you on your having got started in such a healthy and inexpensive way of conducting a local bee-keepers' society. With pleasure, I answer, to the best of my ability, the questions propounded, in order:

The best mode of wintering bees must depend on the locality and other circumstances. As a general rule, I would say chaff hives, arranged as described in the A B C book.

It is never too late to feed for wintering

while there is weather warm enough for the bees to fly.

The best mode of spring management must also depend on circumstances. Watch the bees; love them and help them.

Neither Italians nor common bees will, as a rule, permit a fertile worker to remain in a hive while they have a queen; but the Syrians and Cyprians both at times are guilty of this misdemeanor.

To Italianize an apiary in the spring, without interfering with the honey yield to some extent, might be a very difficult matter; but the advantage of Italian blood would, under almost all circumstances, be such that they would catch up, and more too, before the season is over, so in the end your crop of honey would be greater.

Bees will be rearing brood now where the colony has a young queen, where they have been fed, or where they get late forage; and sometimes strong colonies will raise brood in November any way.

It is *never* best to feed bees sugar, and sell the product for honey. Honestly used to be the best policy, and I guess there is no doubt but that it is yet. Dear friends, are you sure that anybody is putting a product on the Columbus market, under the name of honey, that is only sugar fed to bees? This is a serious charge, and we ought to be very careful that we are right before we accuse anybody.

CARNIOLANS AS COMB-BUILDERS.

NOT DISTOSED TO MAKE PROPOLIS; SOMETHING ABOUT BREEDING THEM.

FRIEND ROOT:—I herewith send you a letter that was written to me, which I think gives more information regarding the Carniolan bees than any thing I have seen in any of the bee-journals; and if you think it worthy of a place in GLEANINGS I should be glad to have you publish it.

CHAS. D. DUVAL.

Spencerville, Md., Oct. 20, 1885.

We give place to the letter below:

Mr. C. D. Duval:—

I have raised over 100 Carniolan queens this fall, and find more yellow in the race than I expected, though some queens, whose bees show considerable yellow at first, raise very nice bees when six months or a year old, as their yellow mostly proves to be a reddish band, as Mr. Benton calls it. But I find there are some Carniolans that resemble the cross between them and Italians. The yellow is in drones as well as workers, and in imported stocks as well as home-bred queens. The first queen I sent you was raised from an extra imported queen; but if she is mated pure it must have been with one of those yellow drones, and those yellow drones you will find to be all through the race; but some queens raise much finer-looking ones, and of a more uniform color, than others.

It is much harder to get good specimens of this race than Italians, and some have so much yellow in markings, that, if we raise them for sale, we shall have to test them and price them according to grade and markings of bees. The most reliable test for some is, that pure Carniolans carry no propolis, but they will make use of it if there is any on frames. I could mail you a piece of duck

cloth for reference, that has covered frames all season. I have two queens that met hybrid drones, and one hybrid queen and several Italian queens mated with Carniolan drones. These queens were raised in the fore part of the season, for experiments. The ones that have black blood in are smaller, with very little down on some, and a rather bad disposition to sting, which the Carniolans have not, as I have not had a smoker lighted; except when uniting them, for three months, or since I got stocked up with Carniolans, and have got but a few stings.

The Carniolans are very hardy, and are the best comb-builders I ever had, and make the nicest section honey. They protect their hives as well as Italians, as far as I am able to judge. I have some Carniolan swarms that built more comb in August and September than the best Italian stands did in the honey season. They also work on red clover as well, if not better, than Italians. But you will find them to swarm more, and some queens raise very poorly marked bees. In raising queens I have much better results after going over my bees the second time, and excluding all queens and drones that had many yellow ones among them. In breeding them I would buy some drones from darkest queens, if they are uniform in color, and also breed from darkest queens. The thing we want is a black underground, or scales, with heavy stripes of down on workers; and queens that raise these without yellow ones among them are hard to get, but they are as fine-looking bees as the best Italians. It takes the very best queens of this race to have good results in raising them; and even then some are not fit to send, as folks will call them hybrids, when pure.

H. F. SHANNON.

Spring Hill, Ind., Oct. 12, 1885.

And so, friend S., you would endeavor to breed out the yellow bands from the Carniolans, would you? It seems to me this is going to complicate matters quite a little. If it is really as you say, that the Carniolans are disposed to show yellow bands, even when not crossed with Italians, wouldn't this indicate that the race itself is a cross? and how are we to know when they have become crossed with Italians, and when they have not? I am glad to hear of the good report you make in regard to them. If it is true, that they collect less propolis, this will be quite an acquisition, and we will take particular pains to notice them in our own apiary next year.

REVERSING COMBS, ETC.

GOOD REPORT OF THE HONEY SEASON.

I THINK that, as others have something to say in GLEANINGS in regard to reversible frames, I have the same privilege. Like all new things, there is more or less doubt; but there is no doubt in my mind as to their utility. I tried a few last season, simply by sawing off the end-bars and driving a long wire nail to take its place, hoping in time something would come along for the much-needed purpose of a perfect reversible frame, and all the while I have been working for it. I tried quite a number, especially the wire you have. I liked that best of all, on some accounts. One great objection is, when we desire to run stays down between the frames, the side wires are much in the

way; and, too, unless they are perfect, the frames will easily hang out of true, and one must have a very nice tool to clinch them to the end-bars.

As we are all a little selfish, I am going to tell you I have made a reversible frame I like best of all. I send you a sample with this. The wire is right in the center of the end of frame, so it can not but hang true, and the frames do move so easy, and no job to reverse the wire! It takes only about half the wire that yours does. To be sure, it takes 3 half-inch screws to an end of frame, but they cost only one cent per dozen, and you see these wires can be used equally well on side-storing frames or on a full set in upper story. I have made a machine to make them on, that cost about 50 cts., aside from a vise that I use. I do not use the spring wire, but the common, as it works much better, and is good otherwise.

SOME ADDITIONAL ADVANTAGES OF REVERSIBLE FRAMES.

I have such a love for reversing, that I shall use such frames, if for nothing but to fill out the bottom of the combs. But there need not be the usual space, if the fdn. is set within $\frac{1}{8}$ inch from the bottom-bar—no matter about a little space at top; that will be all filled. I used to set it up close to the top; and where it was $\frac{1}{2}$ inch too narrow to fill the frame, the space was always left. But the thought occurred to me, that it would work to leave the space above, which is very plain—don't you see? I know that, by having full combs, it takes quite a number less in a certain number of hives; and, too, the bees can reach all the comb quicker, and they are so much stronger, also. By reversing and extracting I can run a queen on seven frames that without would need 8; and how much better the bees take to the sections! I also find that it pays to use full starters in sections, and I learned from W. H. Norton that the starters, to work best, should be cut about $\frac{1}{4}$ inch narrower at the bottom than at the top, and I find it much less work to put such into the boxes, as they do not catch on the sides.

SEPARATORS.

I have used separators wholly this season, and must say I can never do without them, and I have a case that I can use them on or not, and can use a few or more boxes, narrow or wide. I can take out a full box, and replace one with fdn., and it will be filled and no bulging, which otherwise it would be.

I think I have learned one way to foretell when a queen will be killed. When from any cause a queen goes about with her wings up as if she were about to fly, and drags herself along, they are about sure to be killed; at least, I had two Syrian queens and one Italian thus this season. I presume there is some disease that causes her to appear so.

This has been the best season here ever known, and such white goldenrod honey I never saw. I had, I think, 75 lbs. brought in in seven days by one colony (of the best late honey). I have my bees all fixed for winter, with about one-half natural stores, with racks over the frames for $\frac{1}{2}$ -inch passage, and they are mostly on only five frames, and are strong in bees. I have on more warm packing than I used to, for I believe nature is something to go by, as it says, "Stop all upward escapes," and mine that had the most packing last winter came out the best, and ate the least. They are all in chaff hives, and I use a good large bran-sack of leaves over all the cloths, etc.

I am standing on my tiptoes, awaiting the deci-

sion of those bee lawsuits, but I do not fear much, for we must have bees as well as sheep or grapes, and neither are harmed by them. As I grow all sorts of fruits, I have no selfish ends in view.

No. Auburn, Me., Oct., 1885. E. P. CHURCHILL.

Friend C., your reversing device is all right, only that the frames hang on a single bearing. This has been submitted a great many times, and such frames have been used for a time. The objections are, that if you move the hive they swing like a pendulum; and if one side of the comb is loaded more with brood, pollen, or honey, than the other, it throws it to one side. It is true, you can have spacing-strips at the bottom; but then the top must always come in just such a place, and then we have frames at fixed distances again. We thank you for your report of reversible frames in general, and especially for the important facts you bring to light. If you can make seven frames hold as much brood as eight do ordinarily, and thus compel the bees to put their surplus into sections, it will certainly be worth while.—I have often noticed the peculiarity you mention, of queens going about with their wings partly spread; and, so far as I can remember, I have always found such queens faulty in some respects, sooner or later. I do not know that the matter has ever before been in print; but it may be well to warn the brethren, that when a queen carries her wings thus we have good reason to suspect she will not amount to much. Queens, after having been shipped long distances, sometimes show this peculiarity. In regard to the quantity of packing to put over your bees, if you use forest-leaves in a sack, I, too, would say, the more the better; for forest-leaves can not well obstruct ventilation, any way.

A NATURAL CAVE FOR BEES.

HONEY SEASON IN TEXAS.

AT the left of my front yard, a path winds down to a cave some 25 feet below the level, whose cavernous mouth is an arc of 60 paces in front, and would store 10 times as many hives as I have, if needed for winter quarters. Evergreen live-oaks, heavily hung with long gray Spanish moss, with undergrowth of laurel and cedars, cactus villages, algeritas, etc., make a nice mat just over the cave. Right back of our lot is a reservoir, stocked with fine carp, a little over a year old, and over a foot long; and although 12 feet deep, you can see every thing in it and on the bottom, as through glass. Food carp need no feeding here, for its waters, taken from the monstrous spring of 8 acres, grow quite fast the same aquatic plants and grasses that fill the "river head," and it takes a great many carp to keep them down. I think I have the most romantic spot within half a mile of the court-house. There are many fine buildings along the heights. My neighbors (but I refrain from making a letter of length, that perhaps would not interest you), I only wish you could call and see for yourself. Our Texas Chautauqua Literary Society and Summer Institute is also on this height, with our almost boundless view of the prairies.

I ought to say, our many hundreds of Simplicity hives about this place are as overloaded with honey now (although extracted clean in July), as at any time this year. Many are extracting heavily now, and bringing them to one story high. Many new queens are just beginning to lay. I had a fine one hatch to-day, in a full hive. The weather is fine, crops fine, brood heavy yet, and honey and pollen coming in to do the work. The dengue fever has given everybody through here a shake-up.

CARP, AND THEIR UTILITY IN KEEPING DOWN WEEDS.

I wish some enterprising man would dare to come and go into carp-raising, with three ponds on the slope from the reservoir exactly suited to it. I can furnish the ground, and the water is the overflow of the reservoir, always 72", summer and winter. Until carp were growing in there it was often necessary to rake out the masses of spontaneous growth. Now it is gaining on them, and nearly a foot deep on the bottom. I will tell you of Mr. Mitchel's fountain and tank of the hydrant water. He put in some breeding carp where cresses and water-grass were filling up his pond as fast as he could get time to take it out. They grew to great size, and kept things in check. He put brush all around in the water to facilitate laying, etc. This became a mass of glittering verdure, reminding one of a cypress swamp in the Yazoo-River bottoms, densely hung with moss. Well, after the young appeared in thousands, and began to grow, they soon picked the brush clean, and kept nipping the germs, and showing their shiny sides all through it, and they grow like pigs. The large ones are 2 years old and about 23 inches long, 8-pounds.

San Marcos, Texas, Nov. 1, 1885. A. W. BRYAN.

Why, friend B., it seems to me that you folks down there in Texas ought to be happy with all these advantages, and I expect to hear that you individually are now going to settle down and make the most of these advantages, instead of traveling about from one place to another, as you have done for so many years. I can readily understand how a lot of carp may be able to pasture off the weeds and water-plants that fill up your lakes and rivers.

SHIPPING BEES FROM THE SOUTH.

FRIEND MASON GIVES SOME VALUABLE FACTS FROM EXPERIENCE.

ON page 732, Nov. 1, is an article from L. W. Gray, and your comments, which interest me, as we are always short of bees in Maine in spring. I have done quite a large business in shipping bees from the South for the last ten years. I have received bees from more than a dozen of as careful bee-keepers as there are in the South. I have had shipped to me from one pound of bees to full colonies, from April to July, and even August. While some lots came in fine condition, others came all dead, without any apparent cause, packed precisely the same; and while it is a pleasant and profitable business to both the shipper and receiver when a lot goes all right, the next lot, perhaps, is received with a heavy express bill, all dead, or nearly so, which makes the business unprofitable and unpleasant for both the parties. I am satisfied, on the whole, that it is unprofitable to ship bees by rail, where they will be on the road

over four or five days. I find that, where they are more than three or four days in transit, they usually destroy all unsealed brood.

I had one lot of bees the past season from Louisiana. These came by water to New York, and were seven days on the road to New York; then they were sent by freight to Mechanic Falls, Me., which took three days. These bees were in shipping-boxes, on ten L. frames. An opening one inch wide, clear across the bottom, was covered with wire cloth. A 1½-inch hole was made in each end and side, near the bottom, and a 4-inch chamber above the tops of the frames, open at both ends, which was covered with wire cloth; a ½-inch-thick cover had an inch hole in its center; over this hole was tacked a ball of burlap as large as your two fists. This cover was nailed down on burlap, and water poured into this hole, and I have no doubt the captain had instructions to water those bees, and also parties in New York, who see to the transfer of them; at any rate, they arrived here the 11th day after shipment, and there was not half a wine-glassful of dead bees per hive, and the hives were as crowded with bees as I ever saw one that was ready to swarm, and two actually did swarm the next day after they arrived, in regular order, leaving queen-cells all ready to hatch.

I like your idea as to a party being located at some central place, and receiving bees, and letting them have a fly. After they are all right they will stand a two to four days' trip by freight nicely, and come to the purchaser in good order, and reasonably, too, as the expense by water is extremely low. The only question would be, how much this middle-man's services would add to the cost.

Mechanic Falls, Me., Nov. 6, 1885. J. B. MASON.

Friend M., we are very much obliged indeed for your report, showing that what I suggested has actually been put in practice; and from the testimony you give, I should say that this matter of shipping by water should certainly be more fully developed.—The arrangement you mention, for giving the bees water, is also quite an ingenious idea.—So the bees really made preparations to swarm on the way, and did swarm immediately after. Now, then, where is a bee-friend on the sea-coast, who can act as a middle-man for us?

AN A B C SCHOLAR'S UPS AND DOWNS.

HOW HE AT LAST SUCCEEDED; FROM 7 TO 40, AND 1028 LBS. OF HONEY.

THREE years ago I started at about the foot of the A B C class. I thought I possessed more knowledge than I really did. I bought 8 stands of black bees in March, 1883; in June

I had three left. Some swarmed out, and some died. I investigated a little and found nice-nests in the hives, from the size of a tin cup up to the size of a hat. The trouble was, there were but few bees and less honey when I bought them. I learned one lesson then.

A GOOD WORD FOR CYPRIANS.

I had three left in American hives. I watched them closely. They did not swarm that summer. On the 10th day of July, 1885, a swarm of pure Cyprians came and made application for a hive, and, of course, I gratified them. I gave them a hive with old combs. They cast a good swarm the 11th

of August, and a small one the 24th. The last one died in the winter. In the spring I had 2 Cyprians and 3 blacks. The Cyprians increased to 11, and made 375 pounds of comb honey; the blacks did not increase any, and made 125 lbs. I will cut a long story short by saying, last fall I had 23 stands. This spring I had 7. Nearly at the foot of the class again, or, more properly speaking, a fit subject for Blasted Hopes. Not much. My old Cyprian queen came through all right, cast a large swarm May 21st. May 31st another, and June 1st another. The old queen's wings were perfect, but she was so large and heavy she could not fly. From that one stand of Cyprians I increased to 16, and from the 7 I increased to 40. Now take especial notice, they were all natural swarms. You would naturally inquire, "How about the honey?" I took 1028 lbs., all comb honey, in one-pound sections. How is that for Iowa? All but 150 lbs. was gathered after Aug. 1st.

We do not get much honey here yet from white clover, but it is getting a good start. I did not get much from basswood this season. The bees used it in brood-rearing. The most of our honey was gathered from a weed growing in the corn-fields, called by several names, such as smartweed, heart's-ease, and black-heart. The honey is just as white as white-clover honey, and good enough for any one.

ALBERT MCCAY.

East Nodaway, Iowa, Nov. 13, 1885.

THE OTHER SIDE OF BEE-KEEPING.

Or, Rather, a Duplicate of Last Year.

HOW BEE-KEEPING IS LIKE FISHING.

I WENT into winter quarters with 115 colonies. The first of March I had lost two or three colonies, but the most of my colonies were greatly reduced in strength. I thought they would soon build up, but the spring was cold and backward, and brood-rearing was two months later than usual. For the first time, I got a taste of spring dwindling. The first of May my 115 counted 92. The cause of the dwindling was apparent—loss of bees, and backward spring. Old bees died off faster than young ones were hatched. I sold 6 colonies, which left me 86, and transferred 12 on shares, which gave me 92 to commence the season with. I increased artificially to 104.

We had a fair crop of white and alsike clover. The bees got just enough honey from it to check robbing. Linn bloom was never better. The bees got enough honey from that to make them reasonably good natured for eight or ten days, but not sufficient to swarm. August came in cold, and it would have paid a good per cent to have fed them all through that month.

I was in Blasted Hopes last year (that is the name that suits me; when spring came I thought I was out, head and shoulders; but I settled back for five months, just my ears sticking out. Spanish needle came in the first of September, and there was an unusual amount of heart's-ease honey, which began coming in the 2d of September. I put on my first sections that day. Bees got in a good humor, and I felt a little better, and they and I worked together just as if we had always been good friends.

BEE BUSINESS LIKE FISHING.

You can talk to me about mussing with beeswax. Any thing but working with robber-bees. I think mine out in the fall till I don't have many to feed.

They don't sting me much, but they crowd me out, and beat me up in the morning, and can see later at night. There is something in the bee business that reminds me of fishing with a hook. I used to fish half a day without a bite, when I would think of quitting. I would then think, "May be a great whopper is just ready to take hold." When I get a poor crop (which I am sure to do), I think next year I shall "strike oil." Next year some little thing is wrong—perhaps the wind is from the east (as it usually is), but I think the next year will be all right. Next year it is a little too cold, but the next year will certainly be the year. But with all these little things, I like it as well as fishing, and I am spoiled for any thing else. If I don't succeed with bees, I am "gone up," sure.

From my house apiary, 80 spring count, I got an average of 22½ lbs., or 1335 lbs. extracted, 490 comb. Total, 1825 lbs.

From an apiary of 5 on shares, 315 lbs.; my share, 157 lbs.

From my River Apiary, black bees, 12 colonies, average 5¼ lbs., 68 lbs. Total, 2050 lbs.

REFUS ROBINSON.

Laclede, Fayette Co., Ill., Nov., 1885.

Friend R., you say you had quite a fair crop of alsike and white clover, and that linn was never better. Now, if the results per colony you mention are the best you got from all these sources, I should be inclined to call your locality a rather poor one. A good flow from linn alone ought to give at least 100 lbs. per colony, in an apiary of not over fifty colonies.

GIVING A LAYING QUEEN TO A COLONY HAVING JUST CAST A SWARM.

IS THE PLAN ADVISABLE?

ON page 739 of GLEANINGS for Nov. 1, L. W. Gray asks questions for Doolittle to answer, which I will try to do. In the partial answer the editor gives, I see he does not comprehend the question asked, only to a limited extent. The question *mainly* does not refer to the safe introduction of queens, although that is indirectly touched upon, but to the erroneous idea (as I consider it) which has been advanced so many times, that there is a great gain made by giving a colony which has just cast a swarm a laying queen, instead of allowing it to perfect a queen from the queen-cells left after the swarm has issued. As it must of necessity take from 15 to 20 days for the embryo queen which is left in one of these cells to get to laying, we have been told that the bee-keeper who wishes to secure the best results from his bees should have a laying queen ready to give each old colony as soon as they swarm, as the time lost to them, by rearing a queen, is equivalent to a swarm of bees. Being eager to know for myself all the plans which would give the best results, I have experimented largely; and the truth of the statement, that the time lost to the bees by rearing a queen in natural swarming is equivalent to a swarm of bees, is the first reason it has not proven a success. If it were bees I were after, the case would be different. With me, white clover yields enough honey to keep the bees breeding nicely, and prepares them so that they swarm mainly from June 20 to July 5. Our honey harvest is from basswood, which blooms from July 10 to 16. Now, all who are familiar with nat-

ural swarming know that the bees are comparatively few in numbers in the spring, and increase by the rapidly increasing brood produced by the queen, which, in due time, hatch into bees, until a swarm is the result. By giving a laying queen to a colony immediately after it has cast a swarm, we bring about the same result (swarming) as before, for we place the bees in the same condition. The only difference is, that, having plenty of brood, they build up quicker, and are prepared to swarm in a shorter time. As this second swarming, brought about by giving the laying queen, comes right in our basswood honey harvest, it cuts off the surplus honey; for it is well known that bees, having the swarming fever, do little or no work in the section boxes; and if allowed to swarm, the object we have sought after (section honey) is beyond our reach.

REASONS FOR PREFERRING A YOUNG QUEEN.

Now let us look at how the same colony would work had we not given the bees a laying queen. Eight days after the swarm has issued, the first young queen will have emerged from her cell, as a rule, when the apiarist should remove all the other queen-cells from the hive, so that second swarming is entirely prevented. In 8 or 10 days more our young queen is ready to lay, which is about the time the basswood begins to yield honey largely. During this period, between the time the swarm issued and the young queen commences to lay, the bees, not having any young brood to nurse for the last half of the time, consume but little honey; hence, as fast as the young bees emerge from the cells they are filled with honey; for bees not having a laying queen seldom build comb in the sections. Thus, when the young queen is ready to lay she finds every available cell stored with well-ripened honey. At this point the instinct of the bees teaches them that they must have brood, or they will soon cease to exist as a colony, and a general rush is made for the sections; the honey from below is carried above, so as to give the queen room, and in a week we have, as a result, the sections nearly filled with honey. I have often had such colonies complete 60 pounds of section honey in from 8 to 12 days, while those to which I had given the laying queen immediately after swarming, did little else than swarm during the same time. Bear in mind, we are talking about producing comb honey, not extracted. Different locations may give different results; still, I think that nearly all sections give a large flow of honey at a certain period during the season, rather than a steady continuous honey harvest the whole season. To such sections these remarks are especially applicable.

My second reason is, that after basswood we have a honey dearth, hence the bees from the introduced queen are of no value, but, on the contrary, become consumers. On an average it takes 21 days from the time the egg is laid, to the perfect bee ready to emerge from the cell. Then, if the colony is in a normal condition, this bee does not commence labor in the field till 16 days old; hence, the eggs for the honey-gathering bees must be deposited in the cell 37 days before the honey harvest ends, or else they are of no value as honey-producers. As the basswood is all gone before the eggs of the introduced queen become honey-producing bees, and as the larger part of them die of old age before buckwheat and fall flowers yield honey, it will be seen that a great gain is made by letting each old

colony, having cast a swarm, rear their own queen, for thereby we save the expensive feeding of the larvæ, which are to become expensive consumers of the honey of the hive. The chances are, also, that when the colony rears its own queen they will be stocked with younger bees for wintering in November than where a queen was introduced immediately after swarming.

The one point worth knowing above all others in bee-keeping, is a thorough knowledge of the location we are in, as to its honey resources, and then getting the largest amount of bees possible at that or those times to gather honey, having just as few at all other times as is consistent with the accomplishing of this object. If all who read this article will study their location, and then rear the bees in reference to that location, I think they will find their bees will do as well as their more successful neighbors.

G. M. DOOLITTLE.

Borodino, N. Y., Nov. 16, 1885.

Friend D., under the circumstances, very likely you are right; but some way I do not like the idea of ever, under any circumstances, discouraging the production of brood. I presume this, of course, comes about because we have always been in the habit of selling bees, and we sell them almost every month in the year, and therefore they will never be dead property. I can not remember that I ever saw too much brood in a hive to please me; neither have I seen a hive containing too many bees. There is another peculiarity in our location. Bees, as a rule, never swarm after about the middle of July, and therefore we have nothing to fear from the excessive swarming you speak of during the basswood bloom. Where one is working exclusively for comb honey, in a locality like yours, there may be reasons for preferring to have brood-rearing stop for a week or two; but I would always extract when there is an advantage to be gained by extracting.

THE NORTH AMERICAN BEE-KEEPERS' SOCIETY.

FULL PARTICULARS IN REGARD TO IT.

WE extract the following from the *American Bee Journal*:

This society will hold its 16th annual convention on Dec. 8, 9, and 10, 1885, at Detroit, Mich. The hall in which the meeting will be held is known as the "Red Men's Wigwam," and is located at 63 Michigan Avenue, one block west of the City Hall. Just across the street from the "Red Men's Wigwam" is the Antisdel House, which will be the hotel at which the Society will make its headquarters. The regular rates at this hotel are \$2.00 per day, but they have been reduced to \$1.25 per day to those attending the convention. There will be reduced rates on all Michigan railroads, also as far east as Buffalo, as far west as Chicago, and as far south as Toledo. Efforts are being made to secure reduced rates to still further points, but at present the prospects of success are not very promising. No certificates will be sent out until about Dec. 1; but all who expect to attend should write to the Secretary at once, and certificates will be sent out as soon as they are ready.

W. Z. HUTCHINSON, Sec.,
Rogersville, Mich.

RAILROAD CERTIFICATES FOR THE CONVENTION.

As many do not fully understand the use of the certificates to secure the benefits of reduced rates, I will try to explain their use.

It makes no difference whether you belong to the North American Bee-keepers' Society, or any other society, or ever expect to, if you wish to go to Detroit, Mich., to attend the annual meeting of the several bee-keepers' societies to be held at that place on Dec. 8, 9, and 10, you will simply write to W. Z. Hutchinson, Rogersville, Mich., asking for as many railroad certificates as you can use. Mr. H. will book your name and the number of certificates you want, and as soon as he obtains the certificates from the railroad companies, which will be about Dec. 1, he will mail them to you. You will fill out the blank, and when you buy your ticket have the railroad agent fill out his part. If you can not buy a through ticket to Detroit, buy one for as far as you can, and when you procure a new ticket have the agent indorse, on the face of the certificate, that he sold you one full-rate ticket from that place to as far as you get your ticket. You may be obliged to get tickets at several places, but always have the agent certify that he sold you a full-rate ticket.

When you arrive at Detroit, present your certificates to Mr. Hutchinson, and he will fill out the blank left for that purpose, certifying that you were in attendance at the above-mentioned meeting. Then, on presentation of your certificate properly filled out, you will be able to procure a return ticket by paying one-third the regular fare, thus saving to you two-thirds of the regular fare one way.

This is a great reduction, and will enable many to attend at Detroit who would feel that it would cost too much to go. Then with the reduced rates at the hotel it will make your expenses very low. Your committee is still at work trying to make it pleasant for you when you arrive in Detroit. We hope you will all come, and make this meeting one long to be remembered by those present. A large sample room at the hotel has been placed at our disposal; where you can have every facility to show any thing new or of interest to the Society.

Let every bee-keeper canvass his neighborhood, and find how many will attend, then send to W. Z. Hutchinson for certificates as soon as possible, so that he will know how many to apply for.

Clinton, Mich.

H. D. CUTTING.

PROGRAMME.

FIRST DAY.

TUESDAY FORENOON SESSION.—10 a. m.—Convention called to order.—Address of Welcome, by Edwin Willets, President of the Michigan Agricultural College.—Response by the President, L. C. Root.—Calling the roll of members of last year, payment of annual dues, reception of new members, and distribution of badges.—Reading the minutes of the last meeting.—Reports of the Treasurer and Secretary.—Announcements.—Miscellaneous business.

AFTERNOON SESSION.—2 p. m.—Announcements.—Annual address of the President.—Miscellaneous business.—"Production of Comb Honey," G. M. Doolittle, Borodino, N. Y.—"Production of Extracted Honey," Charles Dadant, Hamilton, Ill.—"Marketing Honey," C. F. Muth, Cincinnati, O.

EVENING SESSION.—7:30 p. m.—Announcements.—Miscellaneous business.—Discussion of questions that have accumulated in the question-box during the day.

SECOND DAY.

WEDNESDAY MORNING SESSION.—9 a. m.—Announcements.—Miscellaneous business.—"Bee-Pasturage," Thos. G. Newman, Chicago, Ill.—"Selling and shipping Bees by the Pound," E. M. Hayhurst, Kansas City, Mo.—Selection of place for holding next convention, and election of officers.

AFTERNOON SESSION.—2 p. m.—Announcements.—Miscellaneous business.—"Excellence or Cheapness—Which?" A. I. Root, Medina, O.—"Comb Foundation," John Vandervort, Laceyville, Pa.—"Bee-Keeping as a Business," Dr. C. C. Miller, Marengo, Illinois.

EVENING SESSION.—7:30 p. m.—Announcements.—Miscellaneous business.—Discussion of questions in the question-box.

THIRD DAY.

THURSDAY MORNING SESSION.—9 a. m.—Announcements.—Miscellaneous business.—"Reversing Combs," James Heddon, Dowagiac, Mich.—"The Pollen Theory," Prof. A. J. Cook, Agricultural College, Mich.

AFTERNOON SESSION.—2 p. m.—Announcements.—Miscellaneous business.—“Wintering Bees,” Ira Barber, DeKalb Junction, N. Y.—“Different Races of Bees,” D. A. Jones, Beeton, Ont.—Adjournment.
W. Z. HUTCHINSON, Sec.

FALSE STATEMENTS IN REGARD TO THE HONEY BUSINESS OF OUR COUNTRY.

As a protection to our bee-keeping population, we propose in this department to publish the names of newspapers that persist in publishing false statements in regard to the purity of honey which we as bee-keepers put on the market.

FALSE STATEMENTS IN THE ENGLISH PAPERS, IN REGARD TO THE HONEY BUSINESS.

AFTER reading GLEANINGS for Nov. 1, and seeing the many clippings from papers about bogus honey, I thought I would send you one, especially after reading about your exporting honey to England, and the man saying they would not require more American honey, etc. The inclosed slip is taken from the *Newcastle-on-Tyne Chronicle*, England (my native city). After reading it and your paper, I wondered if the one had any connection with the other. JOHN LILLIE.

Vincennes, Ind., Nov. 14, 1885.

ARTIFICIAL HONEY.

One of the latest American novelties is artificial honey—that is, honey adulterated with syrup manufactured from maize, the method being as yet a secret. Experiments on the subject show, however, that if wheat or maize starch (not potato starch) be treated with oxalic acid, or any other powerful organic acid, a syrup is produced which in a certain concentration, and after standing two or three weeks, exactly resembles in taste and appearance old honey.

Thank you, friend L., but I do not believe our English correspondent had adulterated honey in mind when he wrote what he did. The extract which you send us was probably brought out by what our friends had seen in the American papers. We would suggest to them, that if they want to be fair to the friends over here they will tell what proofs they have, that our corn syrup has ever been brought over from America to be sold as honey. Have the packages analyzed, and find out where they come from. Let us root out the fraud, no matter what it costs.

FEEDING BEES SUGAR SYRUP, AND SELLING IT FOR HONEY.

Below is part of a clipping from the *Toledo Blade*:

Late in the fall, in warm days, feed each swarm until it has ample stores to last till we can commence to feed in spring.

Now, what to feed. In preparing sugar syrup to feed bees, use the best coffee crushed sugar (not granulated, as that will turn back to sugar in the cells), such as is used for cooking purposes. If some of this is stored in the boxes with honey collected from flowers, it will in no way decrease its value, or impair the flavor of the honey.

Feeding bees judiciously is a benefit to the consumer as well as the producer. It increases the product, makes honey cheaper, and does not impair the quality. By increasing the quantity produced by a swarm of bees, it increases the profit of that swarm in dollars and cents; by increasing the quantity of honey in the market it reduces prices per pound, and brings it within reach of all.

Nearly every family with a garden might keep a few swarms of bees with good profit. In commencing, get the best bees in the best hives, and manage them on common-sense principles.

MRS. LIZZIE E. COLTON.

The italics in the above extract are ours. There is no question but that the editors of

the *Blade* meant to credit it to Mrs. Cotton. The letter L was probably a typographical mistake, and her teaching accords exactly with what she says in her book. Of course, she does not directly recommend feeding sugar on a large scale to get nice comb honey, but she very plainly suggests that it may be done, and that nobody will be harmed by it. We call upon the editors of the *Toledo Blade* to recognize the fact that they are encouraging a fraud and imposition upon the public; and we hope that when their attention is called to it they will as publicly protest. We would also remind them that they are allowing one who has been for years published as a fraud, to use their pages as an indirect means of advertising her fraud.

From the *Apiarian* department of the *Rural New-Yorker*, of a late date, we clip the following:

THE ONE THING THAT FRAUD CAN NOT COUNTERFEIT.

I am surprised to note the following response to an inquiry in the *Farmers' Club* of a late *Rural New-Yorker*: “It is probably true, that men, without the aid of bees, now make and sell comb honey in which neither wax nor honey is used; that the comb is made of paraffine, and filled with a substance like honey.” Now, Mr. Editor, I wish to say that the above is not only not probably true, but that it is utterly absurd, mischievously false, and entirely impossible. No such thing has ever been done, and it is very certain that no such thing ever can be done. Only Nature’s deft and delicate fingers can fashion the beautiful comb honey. Comb honey is one thing that fraud can not counterfeit. Whoever purchases the beautiful, white, incomparable comb honey, may be sure that he has Nature’s product, pure and genuine.

A few years ago, Prof. H. W. Wiley, now Chemist of the Agricultural Department at Washington, published an interesting article on sugar, in the *Popular Science Monthly*, in which he made the above statement, apparently in all soberness. Afterward, when Prof. Wiley was called upon for proof of what was palpably absurd to any one who knows of the real nature of comb honey—a substance which is clearly inimitable—he replied: “I only said it as a scientific pleasantry.” This statement was apparently as candid and earnest as any part of the article, and so was widely copied by the press of the country, and now, like all untruthful statements, it is, ever and anon, lifting its ungracious head, only to do mischief.

Comb honey owes its excellence to its very delicate structure. The cell walls of the comb are only 1-140 of an inch in thickness, and thus the delicate wax breaks up in the mouth almost without any extraneous force, and just serves to reduce or dilute the exquisite honey, and so becomes one of the most coveted articles of diet. It seems almost like sacrilege to say that such an incomparable article can be made artificially. As before stated, it is utterly impossible; never has been done, and never can be done. I hope, Mr. Editor, you will publish this correction at once, and that the many papers that have spread the error may be equally quick to fling out the correction; even then much wrong will be done; for, as we all know, falsehood will traverse the globe while truth is hitching up her horse.

Agricultural Coll., Mich.

PROF. A. J. COOK.

Many, many thanks, friend Cook for having struck so effective a blow, at just the right time and in the right place; but it does really seem to me as if the editors of the *Rural New-Yorker* should have added an editorial note, or made some little apology, for their unwise and inconsiderate statement. I want to emphasize Prof. Cook’s words where he says:

No such thing has ever been done, and it is very certain that no such thing ever can be done.

And:

Falsehood will traverse the globe while truth is hitching up her horse.

The trouble is this: When such a wonderful statement comes out in the papers, everybody reads it, holds up the hands in wonder, and every paper copies it. When the falsehood is corrected, however, it is a matter of but little interest to any one, and so nobody cares to read it, and therefore the editors let it drop as quietly as possible; for it is a little humiliating for an editor to admit that he publicly exposed his ignorance. But I tell you, my friends, an editor will make more money in the long run, and get a larger subscription, by being strictly honest, and coming right down to the bed-rock of truth, whenever the cause demands it. The world will stand by a man who, with truthful candor, exposes his mistakes, in a way they will by no means do, if the man is too proud to stoop to undo the mischief he has, may be unconsciously, made. We thank the editors of the *Rural New-Yorker*, however, for what they have done.

AN A B C SCHOLAR'S EXPERIENCE.

FINDING QUEENS; CHAFF PACKING.

NOW that the season is over, and the bees snugly tucked up in their winter blankets of chaff, I feel like summing up results, and reporting to our preceptor. I imagine you holding a kind of inquiry meeting of the A B C class; and having had "sp'ience," I feel like "speakin' right out in meetin'."

I went into winter quarters last year with ten colonies of blacks and one Italian. All came out in the spring with bees in; but on Easter Sunday one swarmed out and went in with another colony, leaving me ten, two of which were pretty weak; but by dint of feeding and building up I got them all to storing surplus on the white clover. Then came the (to me) most embarrassing work: i. e., raising queens, and Italianizing. I approached the first stand for this purpose, with a good deal of trepidation and misgivings, somewhat as a young man ventures to see his best girl for the first time; for although I have had a passing acquaintance with bees all my life I had only once before had an interview, and that very brief, with her majesty the queen. Still, I have succeeded in increasing my ten colonies to 24, good and strong; raising and introducing, for myself and neighbors, 35 queens, with not one laying queen lost in introducing, although I lost several virgin queens in various ways, besides getting a surplus of 1000 lbs. of comb and extracted honey. So much for one of the A B C's. Can any of the W Y Z's beat it?

FIRST: HOW TO FIND BLACK QUEENS.

I have found a way of finding the queen in ten minutes, without staring your eyes out, and, I almost said, to an absolute certainty—at least, it has not failed in a single instance of half a dozen trials. My neighbor, A. C. Moore, is the inventor of the scheme. We help one another a good deal in bee-work, and mutually profit by one another's experience. I had three or four hives I had worn myself out on, trying to find the black queens, and get them out. He had had pretty good success with his own, and proffered to help me. After spending the whole of a hot afternoon in August, without

finding a single queen, most of his conceit oozed out along with the sweat of his face. Next day he tried one of his own, with the same result, when he thought of fastening a perforated zinc honey-board into the bottom of a Simplicity story, in such a way as to sit down over the brood frames, leaving no way of egress around it. Into this he lifted all the frames and bees, and also brushing in all bees from brood-box and bottom-board; then putting bottom-board and brood-box in place, he took up brood-combs one by one, and brushed all bees back into the Simplicity story, with zinc in bottom, and placing frames in brood-box, again. As soon as all were out he put the cover on the box that had the bees in it, and set it on the brood-chamber. Thus he left them 20 minutes or so; and on taking up the cover he found all the bees had gone down through the honey-board into the brood-chamber, except the queen and a few retainers, among which she was easily seen and caught; but when I tried it

THE BEES DIDN'T GO DOWN

of themselves; so instead of the cover I drew over them some mosquito netting and smoked them down. At first I had my doubts, thinking the queen could get through the perforations if she would try seriously; but after watching a not very large queen try for several minutes, I concluded it would be a very small one that did. Of course, the queen might fly up into the air, as many of the bees do, and escape the trap; but so far they never have.

SECOND: A SIMPLICITY BODY FILLED WITH CHAFF.

Instead of chaff cushions I cut a piece of burlap, an inch and a half larger all round than the outside of Simplicity cover. I then take a lath and cut two pieces, one inch shorter than inside length of Simplicity box, and two of them one inch shorter than the inside width of box. To these strips I tack the edges of the burlap—the long edges to long strips, short ones to short strips. Of course, the edges of burlap are much longer than the strips of lath. The excess is equally divided at the ends. I use a frame of lath over the frames similar to Hill's device. After this is put on, and the top box set in place, I put the burlap, with strips to it, down inside of the top box, turn the strips up edgewise against the sides of the box, and with a single lath-nail in each strip, tack them to the lower edge of top box. The ends of the strips come now almost together, leaving just room for the corners of the burlap to gather between the ends of the lath, and leaving the cloth loose enough to drop down over my Hill device, and be pressed down on the frames and cushions at ends and sides. I then fill the upper box with chaff, pressed down. The bees can be gotten at any time by lifting the top box. I think it is cheaper and more convenient than cushions. In the spring, chaff can be thrown out, nails drawn out of lath, and the whole piled up like empty grain-sacks, occupying little space.

IMPORTANCE OF CONSTANT ATTENTION TO THE BEES.

Of course, I have given a good deal of time to the bees—much more than would be necessary to an experienced apiarist. My wife complained that I did not give the bees any time to gather honey last year. In deference to her view I stayed away from them for three weeks, during harvest. At the end of that time, when I brought in a box of moths to burn, her opinion modified somewhat. This year the weaker colonies had my assistance to

fight the moth—at least once a week during their prevalence; and now that six little mouths, and several big mouths, too, are daily filled with sweetness, with big jars and numbers of section boxes set away to sell, the previous remark has ceased to be repeated.

The season has been a good one for honey—the fall, remarkably so. The bees were wild with delight, and kept up a busy hum everywhere in the fields. On the 14th of September I was surprised and chagrined to discover a swarm absconding to the woods, too far gone to be stopped. About the same time, Mr. Moore's wife, when he was gone from home, caught a swarm of black bees. Of course, they were not from his or mine, for ours are all hybrids and Italians. JOHN S. SARGENT.

Hutton, Ill., Nov. 13, 1885.

Friend S., we thank you for your interesting account of your experience, even though you are an A B C scholar. Your plan of finding black queens is the same used by Mr. Quinby years ago, and was mentioned in our bee-journals, and I think it is described in his book, although he did not have the perforated zinc for the purpose, as we do. We have sometimes succeeded by shaking the bees on a sheet, a yard or more from the entrance. As they spread out and crawl in, the queen can usually be recognized. Your plan of tacking burlap on the inside of a Simplicity hive is also old; but as we do not often winter bees in Simplicity hives, the idea has been gradually dropped. I think as a rule, friend S., bees will gather more honey where the hives are opened almost every day, than where they are not so much watched and loved.

INTRODUCING.

A MODIFICATION OF THE DOOLITTLE PLAN.

THE following plan of introducing queens I do not claim as entirely new, but rather a new application of the plan given last spring by Mr. Doolittle, of introducing queens in forming nuclei.

DOOLITTLE'S PLAN OF FORMING NUCLEI.

By the way, I made 25 or 30 nuclei on his plan, and should not want to be deprived of the use of it for the next five years, for \$50.00. Nuclei formed on this plan will often repel robbers in a few minutes after being hived on the new stand, and in an hour or so will be bringing in honey and pollen with a vim; in short they behave precisely like a natural swarm when hived on a new location.

INTRODUCING QUEENS.

First make the swarm queenless, if not already so. I remove the old queen in the middle of the day. If the queen to be introduced is a very valuable one, and the queen to be removed is old, and likely to be superseded, I would wait a day or two to see if cells were started, so as to prove that there were not two queens in the hive. In ordinary cases I would not wait another day, but would proceed just before night to smoke them thoroughly, a little at first, so as to drive them into the combs, and more of it afterward, and at intervals, until they are thoroughly gorged with honey. The bees are then to be shaken off in the hive, and the queen dropped right down among the helpless mass at the

bottom, and the swarm deprived of their combs until morning. If the weather is cool, put the cover on as usual; if hot, put a chip under it to give more air. The combs containing brood may be given to another swarm to care for through the night. If covered up warm, a strong swarm might cover brood for half a dozen others. I return the combs early in the morning, and let them alone for a few days.

Caution.—Before smoking them, see that there is honey in all parts of the hive; if not, it must be given them in some way, as the bees must be made to gorge themselves. This is essential to success.

MY IMPROVEMENT

in the method of introducing queens, as given by Mr. Doolittle, consists in applying the same to full swarms by waiting until night, when all the bees are at home, and also dispensing with the troublesome caging process. I give the following

REASONS WHY I PREFER THIS METHOD

of introducing queens, to any way I have tried:

First, I think it is the surest method extant. I have never tried it with a case of laying workers; but if I had the opportunity I would try it with a good deal of confidence. I introduced queens this fall to over a dozen heavy swarms, mostly vicious hybrids, with perfect success, and that at a time when robbers were bad and bees were cross, which brings us to another reason.

Second, it makes no difference how cross bees are; in fact, during a dearth it seems easier to make bees gorge themselves by the use of smoke, and especially blacks and hybrids, which are the class of bees generally operated on by the A B C class.

Third, This process brings about the same conditions that exist during a flow of honey, but in a greater degree; that is, *all* the bees are gorged; and having no place to deposit their honey, wax secretion is commenced by *all hands*; and after the combs are returned, the cells will be lengthened out with new white wax, even if it is during a time when no honey is gathered.

Fourth, It does not require the skill of an expert to introduce queens by this method. Anybody who knows how to make bees gorge themselves by the use of smoke can succeed every time. I return their combs early in the morning, and contract the entrance, if robbers are bad, as, of course, they would be in no condition to repel robbers until they could disgorge some of their honey. Also, there is no danger of their absconding when deprived of their combs in the night time, even if they were in condition to fly.

CHALON FOWLS, 42—90.

Oberlin, O., Nov. 16, 1885.

The plan you mention, friend F., is not new; in fact, it was given through the journals as much as ten years ago. Friend Alley used to recommend tobacco smoke, in place of smoke from rotten wood, because it partly stupefied them, and I frequently used this plan for introducing queens, when I failed to succeed by any other. I have often made nuclei stop bailing their queens, by taking their combs away, and letting them cluster on the sides of the empty nucleus hives. The objection to it is, the amount of time it takes, and the troublesome process of shaking and brushing the bees off from every comb. With a two-frame nucleus, of course this does not amount to much; but if

robbers are bad, they pitch into these empty combs with a vim, as you perhaps know. Another thing, it costs quite a little honey to make bees gorge themselves during a dearth. I once had a colony with stores enough for winter—at least, so I thought. They were cross hybrids, and I smoked them several different times to make them gorge themselves with honey. This induced them to lengthen out the cells, and build out combs in some places, as you mention. But before I got the queen introduced they had lost at least a half of their winter stores. It had been converted into wax, instead of being put back into the cells. Notwithstanding these objections, I think your plan an excellent one many times. The idea that they commence working like a new swarm, is doubtless true, although I have never noticed it. The loss of queens in introducing, of late years, is much less than formerly. In our own apiary, we do not lose one in 25, even where we put them in rapidly. In introducing 70 imported queens this fall by use of the Peet cage, not one was lost, and they are considered the most difficult to introduce of any queens we get hold of, after their long sea-voyage.

J. H. MARTIN'S DEVICE FOR SELLING EXTRACTED HONEY.

CAN WE SELL OUR EXTRACTED HONEY FOR ONE CENT PER OUNCE, AT WHOLESALE?

I HAVE fallen into the habit of raising extracted honey, and it seems that I am not letting my bees work to good advantage if I run for box honey. Then the swarming, just as they get settled down to business! away goes your swarm, leaving boxes about half full of honey. There is more or less a check every time a swarm comes off. We have run 160 swarms for extracted honey, and every swarm was doing its level best. We had but six swarms from the 160. A lady, whose husband kept bees, visited our apiary and said she was glad to get where she could see some honey. At their house it was swarm, swarm, swarm, and no honey.

When I get my tons of extracted honey, I am then conscious of the fact that I have an article that is not staple. Buyers don't offer you cash for it; if they handle it at all it is on commission, and this year your share would be about what the commission and freightage would be. The great problem, then, has been with me to get my honey upon the market so as to get some money out of it. It is very evident, that if we could convert all of our honey into confectionery, the entire honey crop would not supply the demand. Now, in the absence of a method to convert it into confectionery, the next best thing is a small honey-package. D. A. Jones, of Canada, has given us his little tin boxes; but their appearance is so much like a pill-box, that they don't seem to take on this side of the line. My experiments for a small novel package have resulted in the invention of what I term the "Canteen honey-package." The novelty consists in the fact that the honey from it can be eaten from the hand, like an apple or orange. It is very attractive; and by turning a little crank upon one side, the honey is forced out of the orifice, where it can be bitten off. Candied honey alone is used in this

package. We have tried to educate people in relation to the purity of candied honey; but there is so much adulteration in every thing we eat, it is of but little use to reason with them. Is not a small package a good method to teach the rising generation the value of pure honey? These are the thoughts that have actuated us in preparing this package. We hope it will be a benefit to bee-keepers at large. Honey put up in these packages realizes the bee-keeper 16 cts. per lb. Will it pay to put up honey in such small packages? This question can be answered only by a trial in each bee-keeper's locality from our own experience. We have so much confidence in it that we hope to have several thousand upon the market during the holidays.

Now, Mr. Editor, if I have ground my ax too much in this article, you may just notice my canteen, and refer the friends to my advertisement in this issue.

JOHN H. MARTIN.

Hartford, N. Y.

Friend M., I should almost have known that the machine was of your get-up, even if I hadn't seen your name at the end of the letter, for it is just like you. I will explain to our readers, that the package looks like a common tin blacking-box. A crank on one side makes it look somewhat like a toy music-box the children have about the holiday time. You just take out the cork and turn the crank, and the nice basswood honey oozes out in a square stick, ready to be bitten off. The quality of the honey is excellent; and the only drawback I see in regard to the enterprise is, that it seems to me the machine will cost too much to be afforded so it can be retailed at a dime. Retailers would want to purchase them at \$7.00 per 100, filled with honey. Four ounces of honey would be worth, say, 4 cents, and there would be 3 cts. each for making the machine and filling it with honey. Perhaps I should add, that a strip of colored paper is attached in the form of a bail, so as to make the packet look like a canteen, such as the soldiers use. If any one objects that this is something like free advertising, I would reply that friend M. will never get rich out of it at the prices he offers it.

UPPER ABSORBENTS.

A COVERING OF LOOSE CHAFF MORE DESIRABLE.

M R. HEDDON utters a sentence on page 696, Oct. 15, that strikes me, and one to which I expected the editor to take strong objections. It is this: "I am becoming of the opinion that our upper absorbents are usually useless, and oftentimes worse." It strikes me, because I have arrived at the opposite conclusion. It seems to me that all natural phenomena involved would argue in their favor. But what has most conduced to convince me is actual experience in wintering. I winter on summer stands, in summer hives. I put chaff division-boards in the sides, and chaff cushions on top. This protection on two sides and on top, though far from perfect, perhaps, works quite well. It confines the bees to a small compass, and furnishes a non-conductor of heat, and absorbent above—the direction in which heat and moisture both tend most to go. Usually the top cushions have been only about 1½ inches thick,

with two or more sheets of burlap between the cushion and frames.

Last year I bought, on trial, a kind of L. Simplicity hive. The surplus arrangement of this hive consists of half-stories, into which a slotted honey-board is fitted. After inserting the division-boards I spread a sheet of burlap over the honey-board, and filled the half-story with chaff, making a layer about 4 inches thick. Every one of the six colonies in this style of hive came through in first-class condition. I have found that bees winter best in the sun, because dampness, from whatever source it comes, evaporates more readily. Those shaded will become positively wet, and I find they are more affected with dysentery, and dwindle worse in the spring. Now, every one of these six stood in the shade, and three of them were the most densely shaded in the apiary; yet all kept dry, and all went into summer booming. Of some 25 other colonies in the shade, two died, and nearly all dwindled. The only extra good one was the only one wintered largely on sugar stores. Except in the features named, the chances of all were so nearly alike that I attributed the difference in results to the difference in treatment. I am about convinced that a covering of loose chaff is more than half the battle, and I have told why. Now will Mr. Heddon kindly give us a reason for the faith that is in him?

HOW MANY FRAMES IN THE BROOD-CHAMBER?

Mr. Hutchinson says, page 657, Oct. 1st, that when given but 5 frames they will build no drone-comb; but it is *possible* that, when hived in a large brood-nest, they will build *some*. My experience is, that they will build a great deal, even when allowed access to the surplus boxes at the start. But, does not Mr. H. use an eight-frame hive? Does he fill the extra space with division-boards? Do the bees work as well over these dummies as over brood-frames? Will Mr. H. please explain? Moreover, are those 5 frames enough to accommodate a thrifty queen? Mine that have not swarmed, or before swarming, will use ten frames, and I have had a great deal of trouble with queens (with 7 or 8) going into the sections, because they become crowded below. This is caused in part by the immense quantity of pollen gathered in the spring. They will store enough to almost pack 3 entire frames. This superabundance of pollen often becomes a nuisance to me. Is this locality peculiar for that? Mr. Doolittle once intimated that queens will lay more heavily a few weeks before swarming, or in the early part of the season, than they will after. Is that so? I am inclined to think it is.

Mechanicsburg, Ill.

GEO. F. ROBBINS.

Friend R., I think I agree with you in regard to absorbents over the bees; but as friend Heddon has absorbents at the sides, his arrangement may be such that it answers every purpose. I do believe in having the bees, when wintered outdoors, have all the sunshine that can possibly be given them, and I am also strongly in favor of loose chaff or tolerably loose leaves; and where the material over them is loose I do not think it matters whether it is a foot thick or two feet thick. If it is *packed down* so as to be heavy, it may become damp and sodden, and this we wish by all means to avoid.—I think your locality must be a little peculiar in regard to the quantity of pollen. We never have too much here. Will friends

Heddon and Hutchinson answer the inquiries above?

AUTOMATIC SWARMING.

EXPERIMENTS OF AN A B C SCHOLAR.

AS you request the A B C scholars to experiment with automatic swarming, I will send you the results of my experiments. I can not say that the plan has been a perfect success, but it is simple, and has the elements of success in it. On page 238 of A B C, in speaking of "Odor of Bees," we find it stated, "The odor of a laying queen has a strong attraction for bees," and that they will be attracted by the odor on a person, or a piece of wood, for days after a laying queen has touched it. On page 259 we find it stated, that "swarms are attracted, and are apt to cluster upon the same spot where a swarm has recently been clustered, because of the odor left by the queen of the previous swarm," etc.

Now, putting these two statements together, it is very easy to see that, if we wish a swarm to cluster in any particular place, we have only to manage some way to perfume the spot with the odor of a laying queen, and the chances are strongly in favor of the swarm clustering there; and after the first swarm has clustered there, the probabilities are still more favorable, and increase with each succeeding swarm; and how can we manage to secure the desired odor, more easily and quickly than with queen-cages that have recently contained laying queens? This looks like a very simple problem, and now for the proof:

When I first started out on this plan in the spring, I did not think of trying to get them to enter a hive, but only wished to have them settle in a desirable place; nor did I get them to enter a hive at all, for the simple reason that I had none prepared, when any of the swarms clustered in the place I prepared for them; although, upon placing the hive in position immediately after they had clustered, they readily entered it.

Of all the swarms that issued and settled, some 18 or 20 in all, more than half of them settled on this place, and in no other place did two swarms cluster. Now, by fixing hives on different sides of the apiary, in desirable places, and placing the cages immediately in front of them, in a little bunch of limbs, and placing a shingle, or some such passageway, from the top of where the cluster will be to the entrance, for a bridge, as it were, it is probable, from the success I had, that we can cause nearly all our swarms to enter the decoy hives of their own accord.

Economy, Ind.

GEO. W. WILLIAMS.

If I get your idea, friend W., it is to fix a hive, suppose we call it a decoy hive, on a suitable platform, up in a tree, at about such a height as a swarm would be likely to cluster; give the spot the odor of a laying queen, by putting there a queen-cage, or several queen-cages containing laying queens, or having recently contained laying queens. If a laying queen were there at the time the bees clustered, it would hinder them from going into the hive, perhaps. On this account it might not be best to have any live queens at all; and it strikes me it can be arranged so the bees would cluster on that spot, and go into the hive. When you get home, place the hive where you wish, and substitute another, and so on.

HEADS OF GRAIN FROM DIFFERENT FIELDS.

DOES ERYSIPELAS AGGRAVATE THE EFFECT OF STINGS?

I COMMENCED by purchasing of you a colony of Italians, with which, I am glad to state, I am satisfied. The tested queen produces very handsome workers, and is very prolific. From those Italians I received 25 lbs. of comb honey (15 lbs. white, and 10 of buckwheat); and let me state, I did not get those Italians until the 4th of July; and from this fact, of receiving them on the 4th of July, the anniversary of our glorious freedom, my apiary takes its name. I next purchased 12 colonies of bees from a young man near by, who wanted to sell cheap so as to attend school, and accordingly I purchased what he had, although his father always, since 1870, kept them and was loth to part with his old comrades. He could not care for them, as he was subject to erysipelas, and came near dying by being stung by bees.

I noticed the article in GLEANINGS of Sept. 15th, "Killed by Bee-Stings," and it then came to my mind that that lady must have been subject to erysipelas; in fact, if such be the case, it will not be safe for such people to interfere with bees.

From 3 hives of those 12, I received 144 lbs. of honey, which was very fine. I have increased my bees until I now have 20 swarms to go into winter quarters with. I intend to winter part on summer stands, and part in cellar, as I have one 12x40, and I hope to give a good report next spring.

I purchased an imported queen from Frank Benton, and I am glad to say it met with satisfaction. I intend to import a Cyprian and Italian in the spring. The one I received was a Carniolan, a perfect beauty; and what has been said for the Carniolans, in my opinion, does not half do them justice. Batavia, N. Y., Oct. 28, 1885. F. J. CROWLEY.

We are glad to hear that you think the Carniolans have not had justice done them, friend C.—In regard to erysipelas, we shall be glad of further facts in the matter. Do bee-stings really produce a more aggravated effect where one is thus affected?

REMOVING BEES IN COLD WEATHER, IN CHAFF HIVES.

Can bees be moved in cold weather, in a chaff hive, a distance of about 17 miles, without removing the cushion? F. Fox, Jr.

Cherry Valley, N. Y., Oct. 28, 1885.

Friend F., it might be done without any trouble; but if the bees should get stirred up, and become demoralized, so as to crowd the entrance and the other crevices that furnish air, they would smother. The only safe way is to remove the cushion and fasten the cap down so it can not get out of place, putting a piece of wire cloth over the entrance. They should then be left until they settle down quiet—say an hour or two; then they may be carefully taken up and moved by sled, wagon, or on the cars. If the latter, however, I would, for safety, remove the cover entirely, substituting a sheet of wire cloth in its place, then they can not possibly smother. When they reach their destination, let them stand until they get off the wire cloth and get on the combs; that is, if

they have left their combs. After they recover so as to be in their normal condition, put in the burlap sheet and cushion as usual.

WHERE DID THE EGG COME FROM? ANOTHER POSSIBLE CASE OF A STOLEN EGG.

I read friend Knox's article, headed, "Where did the Egg come from?" and also friend Williams', "Do Bees steal Eggs?" I accordingly concluded to give you a very singular occurrence in my own experience. I got through the winter with four colonies, or all I started with. Two were weak, and I took one about 4 miles away to my father-in-law's, during apple-bloom, as there were but few bees near to build up, and they did very well at first. One day I went to look at them, and I saw they were very strong, and would swarm soon; but as my father-in-law was old, to give him no trouble I told him I would come and divide them, as he wanted a colony any way. So I went over again in 22 days, and, alas! no queen nor eggs, and not a worker-bee in a cell, and only 6 or 8 drones, and they dead. But there were several queen-cells, all empty but one, and that was sealed. So I waited a day or two, and put in a queen-cell, and examined again in four or five days, and found the first one had hatched, and the one I put in cut down and destroyed. Why would all the workers be hatched, and remaining drone-larvæ all dead, if the same queen laid the eggs?

HOW LATE CAN QUEENS BE FERTILIZED?

I tried raising queens from nuclei, and hatched several. Some would be deformed, having but one wing, or some other deficiency, and in a few days disappear. I then tried dividing strong colonies, and made a success of it. One queen hatched about the very last of September or first of October, after everybody said there were no drones. She began laying the first week of October, and everybody said she would be a drone-layer; but her bees are now hatched, and all are workers too. She is two-banded. She is still laying; and of five other colonies, none are laying now, and three quit in September. I fed all of the time, to get into good wintering condition.

It was a very bad honey season here. Several did not get a taste this season. I took only 2 lbs., and I fed, to five colonies and one nucleus, 140 lbs. of sugar. I am going to test the chaff hive for wintering, for the first time. I borrowed two of a neighbor who lost all of his bees last winter, but from having too much elder, I think. E. B. HAUGHEY.

Pearson, O., Nov. 7, 1885.

Friend H., you have been raising queens with nuclei that were too weak in bees. With from a pint to a quart of bees, and all other requisites, we have no trouble with deformed queens, or those deficient in legs or wings.

A REPORT FROM ONE OF OUR QUEEN-BREEDERS:
MORE ABOUT YELLOW-JESSAMINE HONEY.

The bees are having a good time of it, and I have lost many a good queen from the nuclei starving, as I have been sick lately. All my full colonies are overrun with honey, top and bottom story alike, not being able to extract any honey since June. The bees had nearly every crack filled when I saw them last. There is no chance now to take it away, and they will have it to winter on. If I am spared to see next spring, won't I have some tall colonies for early queens? I have some splendid stock now.

I should be very much troubled if we had to look after and prepare bees for winter. The only preparation they get is lots of stores, and they can remain on their summer stand safely. The day before I took sick I placed a nursery with, I think, 13 queen-cells, just ready to hatch, in a queenless colony, and I have not seen any of them since. I knew the queens could not get out, and if something was not done I should lose the colony; and when I am sick there is not any one around I can get to go near the hives, to work among them. So one day three nuclei swarmed out, and all clustered together. I got the hired man to put a veil and gloves on, then he got them in a box, all making a considerable colony. He shook them right in front of the same queenless colony, where he said he saw two of the queens go in safe, and all the bees, thereby making a good strong colony of the one that was for nearly two months without a queen.

YELLOW JESSAMINE.

I have watched carefully all the pros and cons about the honey-poisoning, and have to think, with many writers on the subject, that the poison is not from the honey, or, at least, that from the yellow jessamine, as our woods for miles around abound in it, and it is delightful to walk through them when the flowers are out. I have used and sold lots of early honey, with no evil results. I know of some cases where any honey will give pain to the parties partaking of it. I have a case in our own family, with Mrs. E. She never takes honey that has not candied or granulated, but that she suffers with violent pain after. When it has granulated she warms it and dissolves it, then it is perfectly harmless to her. I believe that the yellow jessamine is very poisonous, and I have seen bees many times in a sort of semi-conscious state, hanging on to the flowers. Not only honey-bees, but carpenter and bumble bees. We have a vine in our flower-garden, trained to a rack, and it is about five feet in diameter, almost a perfect ball; and when it is in bloom it is the talk of all around, a perfect covering of bright orange, with here and there a sprig of green leaves projecting, a perfect nosegay, sending its fragrance for rods around. W. J. ELLISON.

Stateburg, Sumter Co., S. C., Oct. 9, 1885.

Friend E., your testimony corroborates what Prof. Cook said; and I feel pretty certain that an old bee-keeper, accustomed to the use of honey, would have eaten the honey that produced the deaths, in moderate quantities, with impunity.

A REPORT FROM AN A B C SCHOLAR, AND HOW HE SUCCEEDED; A KIND WORD FOR GLEANINGS.

I commenced this season with five swarms, one queenless one. This did nothing but build up during summer. The remaining four gave me six new swarms and 300 lbs. of beautiful extracted honey. I use the Simplicity hive. I had nine swarms in double hives. I took extra bodies away, and put them in condition for winter. October 15th I had 150 lbs. of honey in brood-combs, after leaving them plenty for winter. R. L. James gave me four colonies after taking the honey from them, which I stocked up with my extra combs, so now I have 15 good colonies.

A GOOD YIELD FROM BASSWOOD AND HORSEMINT.

We have had no "bug juice" here this year. White clover is not much to boast of. Basswood gave me a large yield for about 8 days. The season

was short on account of wet weather. The rest was mint as spoken of in A B C, page 152. It commenced blooming about the first of August, and lasted about six weeks. Our sand prairie, along the Wisconsin River, was completely covered with it. Bees worked on it early and late. The honey was very light colored, and of fine flavor. My wife likes it much better than basswood honey.

I had two acres of buckwheat within thirty rods of the apiary, and saw bees working on it but one day, and find no trace of buckwheat honey in the combs. Goldenrod and autumn bloom amounted to but little, on account of cold and rainy weather. My bees are mostly blacks, with a few hybrids mixed in. I handled my bees during a honey yield without a veil, simply using smoke. I like hives well filled with bees, and such I have wintered without trouble in a bee-pit, where the thermometer stood at 35°. I have no luck with small swarms.

I have five acres of alsike, sown last spring. It looks well up to date. I have been in the bee business three years, but never had over 12 swarms until now.

GLEANINGS A WELCOME VISITOR.

A word for GLEANINGS before I close. It is a welcome visitor in our home. I hardly think I could do without it. We enjoy your farm, garden, and poultry sketches as much as the rest, and your home department ought to reach many more.

Wyoming, Wis., Oct. 20, 1885.

J. M. PECK.

Friend P., I presume you refer to the horsemint; and it is interesting to know that it yields honey from Texas to Wisconsin.—I presume the reason why the bees would not notice the buckwheat, was on account of the horsemint honey, which was more to their notion. It is a frequent thing for *Italian* bees to refuse to work on buckwheat while they can obtain white honey from red clover; but at the same time, the blacks will be storing dark buckwheat in considerable quantities.

\$800 A YEAR "AT THE VERY LOWEST ESTIMATE."

We have just received a communication from a Mr. W. Baird, of Pittsburg, Pa., making a broad and positive statement like this, in regard to carp culture:

It requires no capital, and brings in a large revenue, and there is a market everywhere for the fish. There is no doubt but that more money can be made raising fish, than by raising sheep, cattle, or hogs. One-eighth of an acre devoted to German carp will make a profit of \$800, at the very lowest estimate. W. BAIRD.

Pittsburg, Pa.

The same article, word for word, as nearly as I can remember, has been published in some of our agricultural papers; but it seems to me that such assertions are very unwise, to say the least. I should not want to assure anybody that he could make \$800, at the lowest estimate, on bee culture or any other industry, for there are risks to run in launching out into almost any industrial pursuit, and every one must take his own chances. While I am about it, I want to speak of another thing. Of late it is getting to be quite common for a writer to send some communication, word for word, or almost word for word, to different papers. This is surely unwise, and he lays himself

open to the charge of copying as original what has already appeared in print. There is certainly enough to write about, without ever telling the same story over again.

A FAVORABLE REPORT OF THE HEDDON SYSTEM.

We have been trying Heddon's system this year, and it has proved a success. We increased our bees from 16 to 31, and took 1000 lbs. of honey. It has been the worst season we have ever known here—cold and rainy, so the bees could not get out to find the honey, of which there seemed to be plenty. However, we shall not be discouraged as long as they do as well as that, and we have a home market for our honey at 20 cents per lb. We shall try the Heddon system another year; but I can tell you, we have to use the 15-lb. stone to keep the covers on here, and the apiary looks like—a rockery.

G. L. HUBBARD.

Fairview, Lincoln Co., Dakota, Oct. 24, 1885.

SALT AROUND THE ENTRANCES; WILL IT KILL THE GRAPEVINES?

Will not the salt you use and recommend for destroying weeds and grass about bee-hives, in time injure your grapevines as well as other valuable things growing in the bee-yard? I have often thought of salt, but feared the results, so I never used it.

S. T. PETTIT.

Belmont, Ont., Can., Nov. 4, 1885.

Friend P., we have used salt, more or less, in the manner mentioned, for the past three or four years, and I have never discovered that our grapevines were injured in any way. Salt is frequently used as a fertilizer; and though an overdose will kill the crop for the time being, the land soon recovers, and seems to be benefited for a number of years by the application.

A SAD DEATH OF A TWO-YEAR-OLD BOY FROM BEE-STINGS.

The death of that lady in Pennsylvania, from bee-stings, reported in your issue for Oct. 15, page 704, makes me feel like telling you of another similar case that happened not far from here last month. One of my cousins, Mr. Siméon Létourneau, a rich farmer of St. Constant, three miles from here, was keeping bees in box hives. Last spring I sold him 25 Simplicity hives, in which he put all his new swarms, which he put on the ground in his garden. Last September one of his children, a little boy two years old, took a stick and ran after a pig that happened to run in front of the house, and drove it through the garden gate that happened to be open at the time. The pig ran against a hive and shoved it off the platform. The bees flew at the child, and stung him in the face and in the mouth. Mr. Létourneau, hearing the cries of the child, ran to him, took him in his arms, and carried him to the house. In a few minutes the child's face swelled up so that his father became alarmed, and hurried one of his men for the doctor; but as soon as he arrived, the child died in his arms, 25 minutes after he got stung.

J. O. BELLEFLEUR.

La Prairie, P. Q., Canada, Oct. 17, 1885.

Friend B., the story you tell us seems terrible. This little boy was just about the age of Huber, and the poor little fellow was doing the best he knew how, to take care of his father's premises, garden, and bees. I do not know whether any thing could have saved the child's life, under such circumstances. Our readers of the medical profes-

sion have already given us considerable information on the subject, and it is highly important that we should all know all that can be known in regard to the best way of treating such cases. I presume the child was more than usually sensitive to bee-poison, for I have known children when quite small to be stung severely, and yet suffer but comparatively little.

HOW LATE IN THE FALL WILL A QUEEN BE FOUND LAYING, IF NOT STIMULATED BY FEEDING, WITH AN ORDINARY AMOUNT OF PASTURAGE?

I noticed a pretty good colony of blacks, Sept. 21, and there was only one or two combs with brood, and they were nearly all hatched out. No eggs could be seen. I have an Italian nucleus I have been building up, and to-day 25 combs are full of brood and eggs. Can I start the black queen to laying this late, by feeding as per directions in your A B C? I will try.

L. H. ROBEY.

Worthington, W. Va., Sept. 25, 1885.

Friend R., old queens, as a rule, stop laying when the honey-flow ceases in the fall, or as soon as the weather is so cold that the bees stop flying. Queens reared late in the fall, however, will usually keep on with brood quite a little later, and the Cyprians and Syrians will often continue breeding so late as to use up the stores they were allowed to have for winter. You could start any queen to laying at any time of year by judicious feeding, and keeping the colony warm.

APICULTURAL STATION AT AURORA, ILLS.

We are glad to note that the above institution has already got at least partially under way, as our friends will notice by the following:—

In June the Department determined to establish an apicultural station; and although this was very late in the season, the Entomologist thought best to make a beginning this year. The location having been selected, all the preliminary work had to be done, and I did not get settled down to work until in July. I have, however, been able to make progress, as will be shown by my report to the Entomologist.

N. W. McLAIN.

Aurora, Ill., Oct. 28, 1885.

REPORT FROM ALSIKE; HOW A BEGINNER REDEEMED HIMSELF FROM BLASTED HOPES.

I received of you last spring some alsike clover seed, Simpson, spider, and seven-top turnip. The alsike did well. I sowed about three-fourths of an acre, and it is all started nicely. I think by next spring I must get a few pounds more. I did actually raise one spider plant, but it secreted no honey, that I could see, and the Simpson hasn't a vestige. There was not a seed that grew. I tried it in a hotbed and in boxes, in the house, and in the open ground, but not a sign of a plant did I get. The soil may not be right here for those two plants, or else the seed was not good.

I am just starting in bee culture. Last winter I lost all of my bees, and so of course I had to start anew again this spring. I will tell you how I got started. My neighbor, who pulled eleven colonies through, asked me whether I would furnish a hive for every other swarm. As he is a "swarmer" and I am a "hive-maker" (at least I make my own hives and a great many for my neighbors), I told

him I would. I put a lot of hives down for him, and a lot for myself; and as the swarms came off he put one in his hive and one in my hive, and so on, until I got 8 swarms, and I traded him hives for two old ones, and so I have 10 all told. They are all on worker fdn., on the Gallup frame and Simplicity hive, and I think in good condition for winter.

A HOME-MADE EXTRACTOR.

I made an extractor, and just as good as one I could buy for \$10.00 or \$12.00; and all together I received about 150 lbs. of comb and extracted honey, and they are filled for winter since the last extracting. I use 12 frames in the hive, and some of the swarms would scarcely cover two frames. I used a division-board, and built them up on foundation as fast as they could use it. The bees did well on white clover until about harvest; during that time they scarcely did any thing. Then buckwheat soon came in bloom, and they did first rate for about three weeks, and since then they have done very little.

S. B. MILLER.

Amish, Iowa, Oct. 2, 1885.

Friend M., the Simpson and spider plants seem to give a good deal of trouble in the way you mention. With the directions given in the A B C, however, we do not fail to get any amount of plants. But the cheapest way we have found is to take up the seedlings that come up themselves every spring in the open air. In fact, we have never been able to get either of the plants to germinate and grow as well as they do where they come up themselves, out in the lots.

DYSENTERY RESULTING FROM CLOVER HONEY WITH NO POLLEN.

I placed a crate of sections, that had about a handful of bees in it, on a hive; and in doing so I closed the hole in the bottom of the crate, and the bees could not get out. When I took the crate off, the bees were all dead, and the sections wet, and daubed as badly as any that had the dysentery last winter. The honey was new clover honey, and contained no pollen. They were confined about a month.

WM. WITHROW.

Paint Valley, Ohio, Oct. 19, 1885.

Friend W., I hardly think your experiment a fair one. The bees were in an unnatural state, on account of confinement. A handful of bees could hardly maintain the proper temperature to stand confinement safely, as a colony does in winter. I believe, however, we have had several reports of bees that did show something very much like dysentery, where very little pollen was in their stores.

MEXICAN BEES.

Rev. F. B. Ticknor, editor of the *Church Record*, informs me that while on a missionary tour in Western Texas, last summer, in company with another gentleman, they found a colony of what are known here as Mexican bees. They build their comb from the end of a limb, somewhat like a hornet. The men climbed the tree and secured a piece of the honey, and found it excellent. Have you ever heard of them, and what do you know of them? This is the first time I ever heard of them; and from Mr. Ticknor's description they are more like the Italian than the common black bee.

A CAVE WITH LARGE QUANTITIES OF HONEY.

Some years ago I saw, in Missouri, the crotch of

a tree where the bees had built comb sufficient to hold perhaps 20 pounds of honey the previous year, but the bees had all died during the winter. Mr. Ticknor also says they visited a cave where untold quantities of honey were stored. People living in the neighborhood, by means of an Indian ladder climbed up and secured all they needed for their own use; but it would require considerable labor to get to the part of the cave containing the bulk of the honey.

T. F. McCAMANT.

San Antonio, Texas, Nov. 5, 1885.

Friend M., we have had some notice of the Mexican bees you speak of, but we know comparatively little about them. If any of our readers have it in their power to give us further particulars in regard to them, we shall be very glad indeed. It would seem funny, would it not, should it happen that we have bees equal to the Italians, in the southern parts of our country?

BASSWOOD PROPAGATION; QUERIES CONCERNING.

Will you please ask some of your subscribers who have tried planting linden-trees, how they succeeded? I put mine out in the spring of 1884, and last winter the rabbits ate them off very close to the ground. Most of them came up again this spring, but they are all very weakly looking. The tallest is only 15 inches high. I hoed and mulched them, but they do not seem to grow fast at all. I think I shall put tarred paper around them this fall, to protect them from the rabbits.

I sowed the alsike clover you sent me, with barley, and I have a pretty fair stand of it on 6 acres. It is the only field of the kind, so far as I know, in this section of the State. My bees have produced, from 6 hives, 250 lbs. in section boxes.

Garrison, Neb., Oct. 22, 1885. C. H. SARGENT.

No wonder your trees look weakly, friend S., if the rabbits ate them off. Perhaps your hoeing hindered their growth, for we have pretty clearly proven that basswoods make a more exuberant growth in a dense thicket, or in the midst of a clump of briars and brush, than when cultivated in the field, in the glare of the sun.

A CARP SWINDLE.

An apparently extensive and mean carp swindle is just being unearthed at Columbus, Ohio, through the exertions of our association. I will forward the particulars as soon as possible. In the mean time, I will say that developments thus far show that parties at Pittsburgh, Pa., and Zanesville, O., are mixed up in the matter. A large number of newspapers have been inveigled into the publication of a very plausible communication, ostensibly in behalf of the U. S. Fish Commission, but directing readers to address the "U. S. Fish Co." (not Commission, observe), Columbus, O. The postmaster at Columbus writes us that there is no such "Co." as the "U. S. Fish Co." at Columbus, and that some swindle is contemplated, as a great many letters have been accumulating there for the bogus "Co." A second letter, dated yesterday, says a woman has finally called for the letters, claiming to represent some man at Zanesville. The postmaster is holding them.

MILTON P. PEIRCE.

Philadelphia, Pa., Nov. 5, 1885.

Thanks, friend P. Our friends will please take notice, so as not to be humbugged by the "U. S. Fish Co."

REMOVING BEES; IS IT NECESSARY TO KEEP THE
HIVES IN ABSOLUTE DARKNESS, IF THE CELLAR
CAN BE KEPT BETWEEN 40 AND 50°?

Would it be a good idea to keep bees at about 40 or 50°, from the time we have to put them into winter quarters, and in total darkness, without the aid of artificial heat, until time to set them out on summer stands? or would it be better to pack and leave them on summer stands? I thought, by keeping at the degrees above, they would not be subject to the changeableness of the weather we have in this section, and would come out more bright and strong in the spring, but I did not know about the darkness. If kept at 40 or 50° they would not move if they were in the light, would they? or would the idea be any better than the ways we have? J. F. REDD.

Loudonville, O., Nov. 17, 1885.

Friend R., I presume there would be no need of darkening the cellar, providing it could be kept so the temperature would not run above, say, 50 degrees; but I think you will find this is impossible, unless you use ice. Remember, the temperature of the earth itself is 55°, and your cellar will very likely run from 58 to 60° in spite of any thing you can do, unless you get away down into the earth, and cut off communication from overhead. All things considered, I think that, in our locality, I should prefer the chaff hives on their summer stands.

HOW AN A B C SCHOLAR SUCCEEDS BY STARTING
WITH ONE SWARM.

Last spring I took a notion to go into the bee business, and thought I would get 20 or 25 colonies to start on; and as I am a poor man I had engaged \$75.00 to buy my bees with. Being anxious to know something about it, I sent for your A B C book, and in it I saw that I was on the wrong road to success; and instead of buying so many I bought one colony, and now I have three good ones, and I am not in debt \$75.00 with interest. I got 80 lbs. of comb honey. I shall Italianize in the spring, if I can afford it. B. B. MESSNER.

Nimisisa, Ohio, Oct. 13, 1885.

Friend M., I am very glad indeed to know that our A B C book was the means of saving you some money. I had had some experience in the very matter you speak of, and I knew pretty well whereof I wrote, and I think we are safe in saying that it is, as a rule, very unwise for one to go into any business on a large scale, to start with. If he has been for years a grocer's clerk, it may be well for him to purchase a grocery store in good running order to start with; but even then I believe the chances would be in favor of commencing with a small business and building it up gradually.

WIDE FRAMES STICKING TO BROOD-FRAMES; FEED-
ING UNDER THE FRAMES.

Having been a good deal troubled the past season by the sticking of the wide frames in the upper stories to the brood-frames in the lower, I have determined to resort to an expedient, recommended for the difficulty by a correspondent of GLEANINGS; viz., laying strips of glazed cloth over the tops of the brood-frames. Will you or some of your correspondents tell me how wide the strips should be, and which side of the cloth to turn down? I have also thought it might be a good plan to use, instead of strips, a single piece occupying the central part, and leaving a margin of one or two inches all round for

the free passage of the bees. Would such a plan be objectionable for any cause?

After trying various plans for feeding I have fallen upon one which is exceedingly simple, and, so far as I have tried it, it is very satisfactory. It is, to have tin pans so shallow that they can be slipped under the frames at the entrance. To facilitate the work of the bees in getting to the syrup in these pans, I fit a small piece of wood to each side of a pan, on the inside. The pans are so shallow there is no danger of a bee drowning, and the strips of wood—beveled on the inner edge—make it easy for the bees to get at the syrup. In feeding, have the syrup in some vessel with a spout—a pitcher does well—and push the pan three parts under the frames; then fill with the syrup, and push the pan entirely into the hive. A few gentle taps apprise them of the presence of their food. J. A. GILL.

Tuscaloosa, Ala., Nov. 10, 1885.

Friend G., your strips of enamel cloth, or sheet of enamel cloth (the latter being the simpler form), should have openings between every pair of brood-frames, to allow the bees free access to the upper story. You will notice, by our back numbers, that the perforated zinc is much used for this purpose, and the slatted honey-boards. The only objection to the enamel cloth is, that, when perforated as closely as it ought to be, it curls up, and the bees in time gnaw the edges, making it liable to tear.—Your idea of shallow tin pans is quite an old one. The objections are, their liability to incite robbing, and the difficulty of pushing the pans under the frames without crushing bees, and making the colony furious. If you allow more space under the frames than $\frac{1}{2}$ inch, the bees will build little pillars of wax to climb up on, so they can readily grasp hold of the bottom-bars of the frames, and these little pillars of wax are right in the way of pushing the shallow feeders in. The plan seems to have been pretty much all abandoned.

FROM 5 TO 31, AND 945 LBS. OF HONEY; HOW THE IN-
CREASE WAS MADE.

I can now give my report for the year 1885, and will say that I am satisfied with the season. I had the blues "awful bad" last spring. I lost 33 colonies out of 38. Of the remaining 5, one was good, one tolerably good, and the other 3 would have made one good colony, and no more. This is what I have done since May 18th.

I increased to 31 good colonies, and have taken 945 lbs. of extracted honey. I raised all my queens too. If I had had queens already laying when I needed them, I could have done one-third better. I sold one colony and one frame of brood in June. I see in the bee-papers, that Iowa has failed in her honey crop this year. It has been the best season I ever saw, taking it all through, when I have increased from 5 to 31, and have taken almost 200 lbs. per colony, spring count. Ought I not to be satisfied? My queens were all raised from the Syrian queen I got from you, and they are mated with Cyprio-Italian drones. Others can do as they like, but I shall try the Syrians another year. This is the method I practiced in making my increase this year.

The 10th of May I marked my best colony No. 1, and moved it to a new stand and put a hive just like it in its place, and marked it No. 2. In 10 days I

moved No. 1 again, and the one in its place I numbered 3, and so on till I had moved the old colony 4 times, and made 5 swarms by July 1st. Sometimes I would have to move the old colony every 9 days, to prevent swarming. I would always leave a frame of bees and brood on the old location, unless I wanted to raise queen-cells. After the 1st of July No. 1 got ready to swarm, so I made 4 nuclei from this, and afterward built them up from the 4 previous new swarms, so I made 9 from the one, and got 295 lbs. from the increase.

This way I did with all the old queens as fast as they got strong. I always left 6 frames of hatching brood in the old hive, and always moved the old queen. I got my honey from young swarms after they got to work in the upper story. I had all the empty combs I could use.

Now, friend Root, the Syrian queen I got of you from Neighbor H.'s apiary, her bees are all 3-banded; but about a half of her bees have white rings, and are very distinct from those that have the yellow rings. 6—WILLIAM MALONE, 5—31.

Oakley, Iowa, Oct. 26, 1885.

ANOTHER WHO HAS REDEEMED HIMSELF FROM
BLASTED HOPES, AND ALSO FROM TOBACCO.

I have 36 Italian and 10 brown colonies, in your portico and Simplicity hives. I commenced my apiary in 1883. I went into Blasted Hopes and stayed there. I then made a pledge with you for a smoker, on tobacco, and stayed there also. From 24 and no honey in 1883, I went to 36 and 1200 lbs. extracted honey in 1884. I commenced in 1885 with 46 colonies. I had two swarming seasons—in April and in September. I had three seasons of honey-flow.

HORSEMENT HONEY.

In May and June I took from horsement (sample sent), 900 lbs. extracted, and 350 lbs. comb, in 1-lb. sections. July 1st I cleaned up the extractor and put every thing away. Aug. 3d I found the hives full, either of corn, cotton, or sorghum blooms (sample sent). I took 150 lbs. in 1-lb. sections, and 800 lbs. extracted.

MORNING-GLORY HONEY.

Sept. 6th I cleared away, by taking 700 lbs. extracted and 200 1-lb. sections from morning-glories, or tie-vines (sample sent). Total, 2400 lbs. extracted, 700 lbs. in sections. To-day every frame and section is full, and ready to take off—not an empty section to put in, and nothing to put extracted honey in.

TWO QUEENS, NOT RELATED, IN THE SAME HIVE.

I have a red queen, from Viallon, three years old, and her daughter, three months old, in the same hive, laying right along, and I frequently find them on the same frame; also an Italian queen from Tadlock, two years old, with her daughter, doing the same way.

I noticed one of my best and brightest stocks changing to browns. I went in twice to find the cause, but failed. The third time, on the first frame lifted, there was a black queen, laying right along. I pinched her head off. On examination further, there was my old queen, all right, and is doing service yet. I have sold 2200 lbs. of my honey; comb, 12½¢; extracted, 10¢.

Oakland, Tex.

JOHN H. MULLIN.

I am very glad, friend M., to find that you are ahead, or, at least, on the right side of both of these departments—Blasted Hopes

and Tobacco.—The honey you call morning-glory is beautiful in body and color, but not first class in flavor, although it is very fair. It is the first report we have ever had, I think, from this plant.—Your sample of horsement honey is hardly equal to some we have had; but if you get 10 cts. per lb. for it, extracted, I think you are doing well. The other lot I should call a mixture of horsement and cotton, but there may be some other plant that gives it the horsement flavor.—The fact you furnish in regard to a black and an Italian queen laying side by side in the same hive, is a valuable one. Of course, they could not be related, and it goes to show that the matter is certainly within our reach, of having queens that will work together without the deadly hostility that has been so long characteristic of queens. Who will be the first one to advertise a race of queens that will not quarrel with each other? It seems to me there is surely an opening for some one, to both fame and fortune.

TAXING BEES; AND ARE BEES TAXABLE PROPERTY?

I should like your opinion on the subject of taxing bees. Last winter I purchased fifty swarms, and the city assessor assessed them at full value, to which I objected, and at the meeting of the Board of Supervisors I laid the case before our city attorney, and he decided them taxable property. I know of no other bees in this State which are taxed, and think they should not be. Will you please enlighten me on the subject? C. W. RANDALL.

Baraboo, Wis., Nov. 20, 1885.

Friend R., I have several times before expressed my views on this question, and there has been some discussion in the matter; but I hope, if the brethren will excuse me, even where they think differently, for saying that we consider our bees taxable property, and should feel a little hurt and neglected, if the assessor should pass us by. Hives of bees used to be classed with dogs and cats and brush-heaps, and other uncertain property; but it seems to me that, with the present state of progress in bee culture, they should be considered property with other taxable stock. It is true, they are uncertain property, and I should say your assessor had no right to put them in at full value—that is, at the price you offer to sell them. Thus, a hive of bees is worth, say, \$8.00 in the spring of the year; after the honey season is over, may be \$4.00; and perhaps, during the month of December, \$2.50 might be all you could sell them for. Therefore I would suggest that he rate good strong stocks, hive and all, at about \$3.00 to \$3.50. Weak colonies, or those with hybrid queens, etc., rate at about \$2.00 to \$2.50. In localities where bees sell for less prices, \$1.00 per colony might be a fair valuation. We want to do in this matter what is right in the eyes of the law; or, if you choose, what is right before God; and I confess I should feel better about asking God's blessing on the duties of the day, after having paid taxes on my bees, than if I had succeeded by so representing the matter that I got clear of paying taxes. If you don't think as I do about this, I am quite willing you should act according to the dictations of your own conscience. I only wish to have you know how I feel about it.

A GOOD REPORT OF THE BATCHELOR DRONE-TRAP.
FEEDING BEES IN WINTER.

In looking over GLEANINGS for Nov. 1, page 756, I saw a report of friend Batchelor's drone-trap. My experience with two the past season has been very satisfactory. We have caged queens four times, one of them being a clipped queen. It has never failed to cage a queen, that I know of, when it was properly adjusted, and I now exclaim, "No more trouble in swarming; no more hurrying, for fear that the colony will go to the woods; no sawing of a neighbor's trees, or treading down grass." But when I am told that the bees are swarming, and as soon as they begin to cluster (which will be on the trap), I place them at the entrance of the new hive, release the queen, and when the bees are nearly all in I give the hive a new location, and place the trap on the same, which will prevent them from leaving the hive, which they might do if it were not for the trap.

A TYPOGRAPHICAL ERROR.

Page 755, GLEANINGS, in speaking of feeding bees in cold weather, you say there is a danger of the queen taking wing. Why is she more liable to leave the combs in cold weather than warm, as we have rarely known them to leave them in warm weather? With the feeder that we use there is no danger of the queens leaving the comb, or of the bees being drowned. I also notice, on page 748, an item in regard to a bad odor about the hives in the fall of the year. If it were here in New Hampshire, I should call it the goldenrod.

A. H. HARVEY.

Keene, N. H., Nov. 19, 1885.

Friend H., you have got hold of a very bad typographical error. I had no thought of saying that the *queen* took wing in cold weather, or under any other circumstances. It should have read that the *bees* take wing. The blunder escaped my eye, and also the eye of two proof-readers.

UNTESTED QUEENS FROM THE SOUTH IN THE
WINTER TIME.

I should like to take advantage of your very clever offer in GLEANINGS, of a free advertisement for Southern queen-raisers. If you will, you may announce that I will furnish Italian queens by the half-dozen at 80 cents each; or single queens, at 90 cents. What about guaranteeing safe arrival? I will leave it to you to insert or not. To the Southern States it would be safe to guarantee safe arrival; but to the colder States it seems to me that, in case a queen died, another one at half-price would be fair, or charge \$1.00 in the first place. I will simply state what I wish to accomplish, and let you insert what, in your judgment, you think best. I shall be more anxious to get my name before the bee-keepers than to make money; still, I do not want to lose any. I have no bees but Italians. The young queens will be raised from a choice, select, tested queen. I have over 20 colonies and nuclei, but only a dozen are run for queen-rearing. Please announce *only* what you think best. L. W. GRAY.

Orlando, Fla., Nov. 21, 1885.

Friend G., I think it would be better for you to make the arrangement directly with your customers, although I will suggest, if you wish. I think you had better keep the price at \$1.00 in the winter time, and replace where the queens are evidently dead from want of care in putting them up. This, of

course, will call for a little charity on your part, as well as on the part of the friends who receive them, in deciding where the fault is. We received some queens a few days ago, when it was quite cold. They were put in wooden cages, without any metal except the wire cloth, and were packed in several folds of soft flannel. Not a queen nor bee was dead.

Friend G., the important matter is, Have you some untested queens all ready to mail now? You do not say you have or have not; but we want somebody who has the queens all ready to ship, and we want them to advertise in this way; like this, for instance:

Ready to Mail.—I have 17 young queens that have just commenced to lay, which I will ship promptly at \$1.00 each. Safe arrival guaranteed, if they are uncaged and handled according to the printed instructions accompanying the package.

JOHN JONES.

The printed instructions accompanying the package should be something like this:

Keep this package out of the frost as much as possible. Unroll it in a moderately warm room; and if the bees and queen seem chilled, leave them several hours where the thermometer stands at 70 degrees, before you decide they are dead. When they begin to move, a little warm honey might be given them on the point of a pin; but don't daub the poor little fellows, whatever you do. When they are lively, introduce them according to the usual method.

Halloo! here is one name already, and it is not from away down south either:

Please insert my name in GLEANINGS, for sending queens during the winter months as you offer to do free of charge. I have a number of untested queens on hand, and can fill orders by return mail.

Mechanicstown, Md.

SIMON P. RODDY.

And still another:

I have 18 untested queens which any one can have at \$1.00 each, by return mail.

Stateburg, Sumter Co., S. C. W. J. ELLISON.

SOME KIND WORDS FROM FRIEND PARSHALL, AFTER HE GOT OVER HIS FURT (SEE P. 345).

I have been wanting to write for a long time, mostly to thank several of the bee-brethren, and some of the sisters, who have written to me, sympathizing with me in my loss and bad luck. There is one, Sarah J. Axtell, Roseville, Ill.; H. J. Hancock, of Siloam Springs, Ark.; Mr. Hughes, of Illinois, and a brother at New Orleans. I thank some for sending queens and others offering me bees. Some of their addresses I have lost. God is the only one who knows how my heart swelled with gratitude, and how I say, "God bless them." I want them all to feel that I appreciate their offers to me, just the same as though I had accepted them. I was so badly crippled that I could not do a lick of work till in July, and this is my first writing. It was my "write" arm and hand that got terribly mangled. I can not shut my hand yet.

MY REPORT.

I commenced the season with seven colonies—six good, one very weak. I increased to 35 by natural swarming; have taken 1500 lbs. of extracted and 600 lbs. comb honey. I am selling my honey at home for 10 cts. for extracted and 15 cts. for comb. I have sold the most of it. My bees all have lots of winter stores. God has wonderfully blessed me,

and my prayer is that he may bless you all, when I think of the many kind letters I received. I know I had many prayers. It leads me to say, "O Lord, bless all of those good people." JAMES PARSHALL.

Skidmore, Mo., Oct. 25, 1885.

Friend P., we can unite with you in saying, "Let God be praised that he has enabled you to regain your strength so you can write at all." We are very glad to know that you have been prospered in bee-keeping once more. We as bee-keepers are always glad to extend a helping hand to those who have a disposition to help themselves, and you have shown this pretty well.

KIND WORDS IN REGARD TO THE POTATO-BOOK.

After reading your account of your visit to Terry, I felt that I could not refrain from urging you to give us a full account of his system of farming and his buildings; and could you not also induce D. E. Fenn to tell us how he manages to get an average of 37 bushels of wheat per acre, as mentioned in the potato-book? Give us another book on Terry's farming, I say. EDGAR HUSBAND.

Cairngorm, Ont., Can., Sept. 29, 1884.

Friend H., Mr. Terry is now at work on another book for me, to be a sort of supplement or sequel to the potato-book. It is to be in regard to the humane treatment of farm stock during winter, considered from a pecuniary as well as moral standpoint. Mr. D. E. Fenn gets his large yields of wheat by the use of phosphate. Mr. Terry does not have any success with phosphate, as you know; but Mr. Fenn is an enthusiast in the matter, and yet both are good farmers. The difference in the soil may have something to do with the different results they get.

TIERING UP.

What is your opinion of tiering up the hives in the cellar in this wise? Place the strongest colonies at the bottom, one in each tier, with only a bottom-board, then a cover of wire gauze, over which two thickness of burlap or other porous material, then another hive in like manner, until four or five high, placing the weaker ones at the top, with good ventilation at the top, and leaving the entrance open; and for a "playground," put wedges between the hives, to project out to hold up said burlap. The object of said tiering up is to produce an upward draft and consequent good ventilation.

Glenn, Kan., Sept. 14, 1885.

W. B. THORNE.

Friend T., there is no objection to the plan you mention, that I know of, except that of jarring the hives in handling. When we wintered in a bee-house we preferred to have shelves, so that taking down one hive did not disturb another. I think your burlap had better be drawn back so as to expose the back end of frames containing very strong colonies, or they might be too warm. A strong colony fastened in its hive with wire cloth is very apt to cover the ventilators, and smother, unless the ventilating spaces are very large.

STRANGE FEAK OF A QUEEN-BEE.

Yesterday, after I had finished extracting some combs taken from hives contracted for winter, I accidentally left the extractor so the bees could get

at it, which they soon did. About 3 P. M. I went to remove it to the honey-house, when, among the numbers of bees, I found a queen-bee, black. Can you explain what she was doing there? I thought that the queen never left the hive, except when mating, or else when she issued forth with a swarm. I put her in a cage, and hung her in a hive after showing her to several present, who were as much astonished as myself. If you can enlighten me on the subject, I should be pleased to hear from you.

Parkersville, Pa., Oct. 24, 1885.

J. P. TAYLOR.

Friend T., what you state is a very unusual thing indeed. You are sure, I presume, you did not get hold of a shiny black robber-bee, with an elongated body, and call it a queen. If the bees had been very long at work at that extractor, the effect might have been to break up a weak colony; and the bees, queen and all, might have been attracted to the extractor by the roar of the robbers.

A SAW AND PRUNING-SHEARS COMBINED.

SOMETHING TO CUT OFF LIMBS, AND DO IT EASILY.

A FEW days ago Mr. Gray had some kind of a machine on the end of a pole; and as some of our basswood-trees along the sidewalk near the store were getting to be rather luxuriant in foliage, he reached up and cut off some of the limbs which were not wanted, and as easily as you would cut off a piece of cheese with a knife. The picture alongside of what I am writing explains how he did it, only you are to imagine the implement on the end of a pole from six to twelve feet long, as may be desired; and the wire which you see is attached to a hand-lever to it in such a way as to give it a powerful purchase. I told him the machine would be ahead of a buzz-saw for cutting up stove-wood, as you can not carry a buzz-saw out into the woods, but you can easily take this along, for it is not much heavier than an ordinary ax. You will find his advertisement in another place, and he will send you a circular, telling all about it, if you write him. The price of the pruner is \$2.00, and it can be sent by mail, without the pole, for 40 cts. extra for postage.

THE POLLEN-BASKET.

WHERE IS IT, AND WHAT IS IT LIKE?

I VENTURE to take up this subject, because I think it is so generally misapprehended. While many have an indefinite idea of what a pollen-basket should be, and much less know where it is situated, very few can form a perfectly correct idea of what it is like. I have been for some time trying to get a good drawing of the pollen-basket — one that is correct. While I do not claim to have made an accurate representation, yet in some particulars I think it is ahead of any thing else.

After our engraver had submitted several drawings to me without success, I made several myself before I could get any thing that at all suited me. It is a difficult matter to get the engravers to understand exactly what features we want made prominent, at the same time preserving all the proportions. I therefore have had to tax my ingenuity with the pencil several times. Below is a portion of the hind leg, with the foot (not shown) toward

THE POLLEN-BASKET.

the base. The letters F, B, C, and F, inclose what is known as the pollen - basket. In the central portion, marked by D and A, is a depression that is dishd out, somewhat like a spoon. Around this cavity is a rim of hairs which form a kind of inclosure. This rim of hairs, together with the depression, makes what is termed the pollen-basket, though it is a little strange why it should have been called a basket. I presume, however, the name was given to it because it conveyed the idea much better than any thing else. It is in this that the bee packs the pollen which he collects. As far as I have been able to ascertain by observation, the bee always puts the pollen in this part of the leg, and never anywhere else. It would be presumption for me to differ with Prof. Cook on this point; so I will say that, in all probability, I misapprehend his meaning (see his Manual, page 88). He says, "On the outside of the posterior tibia and basal tarsus is a cavity made more deep by its rim of hairs, known as the pollen-basket." I understand this to mean, that the pollen-basket is situated on both sides of the joint C; that is, that the pollen may be parted both in the upper and lower segments, as at A and E. Since my attention has been called to this matter I have watched the bees gathering pollen repeatedly at several different times, and I have never yet seen them deposit pollen anywhere else than in the portion marked by F, B, C, F.

HOW THE BEES PACK THE POLLEN ON THE HIND LEGS.

If I am correct, no one has yet told us just how the bee deposits pollen on this hind leg, further than that it is by a sort of sleight of hand with the fore and middle leg, in conjunction with the tongue. We know, or we think we know, how the bee separates the pollen from the tongue and the front legs by means of the little flute mentioned in the text-books. The question now remains, How does the bee get the pollen from the front leg to the

hind leg, and exactly how does the middle leg transfer the pollen to the baskets? I have often watched the movement, but it is so instantaneous that my eye was unable to catch the exact process. If the bee only *would* do it slowly, so we curious mortals might see! but, no; he does it as though he had acquired this wonderful feat by long practice — or, rather, by instinct.

There is another obstacle in the way; namely, that the bee won't remain still long enough — as though modesty or bashfulness forbade him the privilege of "showing off." I have watched one tugging at a pellet of wax, and, after placing it under his chin, as if by magic deposit it in the basket; and when, again, I thought he would try it again, lo and behold! he would soar away, leaving me lamenting that the precious little secret had not been revealed.

To one who has a love for studying God's wondrous works of creation, it will be found eminently interesting. I know, dear friends, that the settlement of this and questions of a similar nature is not of vital importance; but, does it not in itself, as we observe the wonderful symmetry and plan in a thing so very small, bring us near the Maker?

Perhaps I should state, that only a small magnifying-glass is necessary to look at this pollen-basket — such a glass as I speak of just below, in answer to Mrs. Chaddock. ERNEST R. ROOT.

MRS. CHADDOCK ASKS SOME QUESTIONS FOR ERNEST TO ANSWER; MAGNIFYING-GLASSES, ETC.

I am very much interested in Ernest's microscopic work, and I wish he would examine the eye of the bee, and make a drawing of it; tell where it is situated, etc. I have only a small magnifier (bought of A. I. Root, for 35 cts.), and with it I have not been able to find any thing that looks like eyes. I turned the bee over, and looked at it up and down, around and about, but not a single eye could I see, unless those two little round knobs on top of the head are eyes. They look like immature shoe-buttons, and seem to be in an unhandy place for eyes. Then there are some more little knobs where the feelers start out. They are fast on the feelers, and move with them, and so I suppose they could not be the eyes. It would be a very safe place for them, as the feelers could always keep them from getting knocked out or off; and after he has made the eye plain, I wish he would give us the ear, if they have any ears. MAHALA B. CHADDOCK.

Vermont, Ill.

Here is Ernest's reply:

Thanks, Mrs. C., for your kind interest in the work that I have begun. I shall be most happy to give you drawings of the bee's eyes, and other microscopic organs of the bee in our future issues. As I have all the needed facilities for this work in the way of a good microscope and lenses, as well as dissecting tools, I can verify old discoveries, and possibly add something new in this department of science. The 35-cent magnifying-glasses give very satisfactory results, though not quite equal to a Coddington of same power, in quality of work. You must not imagine that a high-priced microscope or lens is essential to gain a correct idea of the various functions of the bee. In my work I use a small magnifying-glass much more than my high-priced instrument, though the latter in some cases is indispensable. The apparatus necessary for dissecting a bee may be simple and inexpensive. You need,

first, a glass of about 10 diameters magnifying power (like one you have), a pair of fine-pointed tweezer, scissors suitable for clipping queens' wings, a needle mounted in the end of an old pen-holder, and a little ether or chloroform with which to stupefy a bee while "cuttin' 'im up." You now have a very fair outfit with which to begin. No doubt you will find pleasure and profit in this work; that is, providing you do have such a thing as spare time during long winter evenings.

There is one essential that I almost forgot, which is, that you must have a good stock of patience. If your eyes or back aches, don't complain.

ERNEST R. ROOT.

NOTES AND QUERIES.

REPORT OF AN A B C SCHOLAR.

I PURCHASED my first stand of bees in the spring of 1884. I increased to three stands, and took 60 lbs. of honey the first year. Last winter I sent for the A B C book and GLEANINGS.

I began last spring with two stands; transferred them to Langstroth frames, and took 190 lbs. of honey—140 lbs. in sections, and 50 lbs. in brood-frames. I increased to 10 stands, and all in good condition for winter. It has been called a poor season by the old-style box-hive bee-keepers, not one of whom has obtained half as many new swarms, or half as much honey from the same number in the spring. I attribute my success the past season to a thorough, earnest study of GLEANINGS and the A B C. A. C. BUGBEE.

Lochiel, Benton Co., Ind.

My two hives yielded \$36.00 worth of honey, and have plenty to winter on. They cost \$17.00—a good investment on that amount of money in 7 months.

Harlan, Iowa, Oct. 9, 1885. W. M. BOMBERGER.

Bees are a failure this year. Only a few colonies made any surplus. I have about 80 colonies, and perhaps half of them will not winter without feed. Washington, Pa. L. W. VANKIRK.

SOUR SMELL—WHAT CAUSES IT.

I have investigated into the cause of that sour smell about the hives, mentioned by friend Scofield, and find it comes from the blue aster.

Ridgeway, N. Y. D. C. SULLIVAN.

A QUEEN THAT MEASURES FIVE CELLS.

I raised one queen this year that measured five cells long; that is, she would reach or cover five cells. Who can beat it? She was a Syrian.

Oakley, Iowa, Oct. 26, 1885. WM. MALONE.

ALFALFA AS A HONEY-PLANT.

Almost all the honey made out in Tulare Co. is made from alfalfa. That seems to be the main crop for honey this season. I like California pretty well, but it is terribly hot in the summer.

Hanford, Cal., Sept. 8, 1885. M. J. TWINING.

This has been the poorest year ever known in this section for bees. But few colonies will winter without feeding. My spring count was three; increased to 7; fed 43 lbs. of granulated sugar. At present I have but two colonies and two nuclei, which I intend to take to Florida this fall, as described in GLEANINGS of Feb. 1, 1885, page 97.

Harrisonville, N. J., Oct. 19, 1885. J. D. COLES.

REPORT FROM OREGON.

I will give you our report from Oregon, or I should say, perhaps, the northern part of the Willamette Valley. Bees, we think, have done tolerably well. Reports of 50, 75, and 100 lbs. of surplus are made, and bees are booming now. The fir-trees in many places are dripping with honey-dew. We have warm days, and have had for some time.

Newberg, Or., Oct. 2, 1885. CYRUS E. HARKINS.

FROM 4 TO 11, AND 277 LBS. OF HONEY.

Bees generally did well. They did but little on buckwheat or fall flowers, except on boneseet. I started in last fall with 5 colonies on summer stand, in chaff, and came through with four—one very weak. I have 11 now. I took 277 lbs. of comb honey. Thanks for your good words in GLEANINGS. If it were not for the assistance we beginners get through the pages of bee-journals, bee-keeping would be up-hill work. GEO. SPITLER, 4—11.

Mosiertown, Crawford Co., Pa.

THE SIMPLICITY VS. THE GOLDEN HIVE; 175 LBS. OF HONEY FROM ONE SWARM.

I had four stands of common bees in Simplicity hives last spring; sold \$20.00 of bees and honey, and have 100 lbs. of honey and five stands in good condition for winter. My first swarm, on June 3d, made about 175 lbs. in 1-lb. sections. About 50 lbs. of it was the nicest linn I ever saw. But bees do not fill out sections with it as with some honey I have seen from Michigan. Is it the bees, or does the honey come in too slowly? The "Golden" hive had quite a run last year, but it makes them sick to mention "Golden" now. Several will discard them, and use your Simplicity. G. F. AYRES.

Atherton, Ind., Nov. 11, 1885.

MRS. COTTON, AGAIN.

MORE \$20.00 COLONIES CONTAINING NO QUEENS.

I HAVE been humbugged by Mrs. Cotton, of West Gorham, Maine. I sent her \$20.00, and she sent me a Controllable hive and a few bees, but no queen. I wrote her about it, and she has agreed to send me another colony, in the spring. I made a few of her hives, and have five swarms in those hives now, but I don't like the hives, and don't think I shall make any more of them. I bought five colonies of Prof. A. J. Cook, of Lansing, pure Italians, *very fine*, but they were Gallup chaff hives, and I don't like this hive. I think I shall adopt the Heddon or the Simplicity hive. HIRAM ADAMS.

Port Austin, Huron Co., Mich., Nov. 23, 1885.

Our friends will notice that this is still another complaint of no queen in the colony of bees, even after the purchaser paid the enormous price of \$20.00 for it. The price would not be so very bad if the colony were sent very early in the spring; but Mrs. Cotton, I believe, does not fill orders until along in the summer, when bees are comparatively cheap everywhere else. The number of complaints that come in regard to these high-priced colonies being queenless, precludes the possibility of its being a mistake; and her singular directions, not to open the hive for a certain number of days, also seem to indicate it to be her regular way of doing business.

MEDINA, DEC. 1, 1885.

He that hath the Son hath life; and he that hath not the Son of God hath not life.—1. JOHN 5: 12.

STANLEY'S AUTOMATIC REVERSING EXTRACTOR.

FRIEND STANLEY informs us that one of these for taking four L. frames will be on exhibition at the convention in Detroit.

DISCOUNT ON GOODS FOR NEXT SEASON'S USE.

As trade is still comparatively dull, we extend our offer until Dec. 15, or an extra 5 per cent on every thing you order now, on goods to be used next season.

THE CONVENTION AT DETROIT.

I EXPECT to be on hand to assist all I can, on the morning of Dec. 9, the very day I am 46 years old, Providence permitting; and may the Lord be praised for the 46 years of life he has given me already!

THE MAN WHO NEVER LOSES BEES IN WINTER.

We are glad to know that friend Boardman will be at the Detroit convention, and we expect to have a good time in making him tell all about how he fixes his bees for winter. See card below, received just as we go to press:

The bees are all safely stored for winter. I finished setting them in day before yesterday—550 colonies in four repositories, two bee-houses, and two cellars. Now I am all ready to go to Detroit to meet and exchange notes with my brother bee-keepers.
H. R. BOARDMAN.

East Townsend, O., Nov. 27, 1885.

A WHEELBARROW TO MOVE CHAFF HIVES.

J. A. ALTHOUSE, New Harmony, Ind., sends us a model of a wheelbarrow, made to catch up chaff hives so they can be conveniently lifted and carried anywhere, no matter how much honey they contain. I should think the arrangement might prove a convenience to those who practice moving hives after a swarm is cast. The same wheelbarrow has a box that can be quickly put in place, so it will answer all ordinary purposes of a wheelbarrow. Friend A. will doubtless furnish particulars on application.

REDUCTION IN THE PRICE OF THE MUTH HONEY-JARS.

WE are pleased to note that friend Muth has come down a peg on his prices as well as everybody else, and we can now furnish any of his honey-jars at 5 per cent discount on single-gross lots. For two or more gross, 10 per cent. These very close prices can be given only with cash with order, or from some man whose name is good for the cash promptly whenever we see it. We have such men on our books, quite a few of them, and we thank God for them when we look at their names. The jars are all to be shipped from Cincinnati. If you want them shipped with other goods, we shall have to add freight from Cincinnati, which, however, is but a trifle.

DON'T LEAVE YOUR BASSWOOD LUMBER TOO LONG IN THE LOG.

If you want to make nice white sections, cut your logs, draw them at once to the mill and have them sawed into plank, and then have the plank stacked up as described in the A B C book; but have the lumber lie lower at one end than at the other, so the rain will run down and off at one end. This is especially important in the winter time. A covering of boards over your pile of plank will pay the expense. Now, in spite of all we can say about this matter, a good many of our farming friends will persist in letting the logs lie, say a month or two, and during that time the white basswood becomes dark, or of a sort of yellowish or smoky color. We have just now been working up such a lot of lumber, making about 50,000 sections. The basswood, when cut, was first quality; but owing to this one little item of neglect, we offer the whole lot at a discount of one-fourth. They are too nice for culls, and hardly fit for first quality. If any one wants a bargain on such sections, now is his chance.

THE OUTLOOK FOR 1886.

No one knows just what the honey business will be next year, any more than we know what the coming winter will be; but, of course, it behooves every man who wants to be considered progressive and straight, to be prepared for the worst. Many were surprised by the severe weather of last winter. Now, instead of presuming that this winter will be a mild one, let us make preparations for just such a winter as the last, or even a worse one. In regard to business for another year, let us be prudent, and use economy. I do not believe it is well to get into debt very much. A little money ahead, ready for such an emergency, or for any change that may offer for a good investment, is always wise. A man's powers, both of mind and body, are crippled when he is all the time crowded, and short of means. Make expenses come a little below the income, even if it takes almost a leg to fetch it. When you once get into the habit of saving a little every week or every month, you can do it just as easily, and with a good deal more satisfaction, than where you get a little more in debt every week or every month; and one who is hopelessly in debt is hopelessly a cripple, and a cripple all his days.

CALIFORNIA HONEY.

WE have just received a carload of honey from friend S. G. Miller, of Capistrano, Cal., which I believe is the finest honey, in every respect, that I have ever before come across. Of course, this is my taste; and tastes, you know differ. Well, with all its other good qualities this honey does not candy, even when exposed to the most severe freezing. You can fill large bottles and jars, and they will be just as limpid and transparent after standing a month in the window as when first put into the bottles. The honey is very thick and heavy. It comes in cans holding 58 lbs. each, and the price will be, can included, 9 cts. per lb. Two cans are crated in a strong box; and if you take one of these whole original packages you can have it for 8½ cts., or an even \$9.75. We also put it up in 5-lb. screw-top cans at 10 cts. per lb., can included. We also have it put in Muth's dime honey-jars, for sample package, to let people taste. It seems to me it should have an immense sale at these figures. We will send a very small quantity—enough to give you a taste—by mail, free of charge,

COMB FOUNDATION.

We have just purchased a large lot of fine beeswax at a bargain, which will enable us to sell fdn. very cheap for cash.

NOW IS YOUR TIME TO PURCHASE.

Our fdn. will all be manufactured on the celebrated Given press. Write for special rates to dealers and large consumers, stating how much you want, and what kind, whether thick or thin. We send sample of foundation free. Our Price List of

APIARIAN * SUPPLIES

for 1886 sent on application. Estimates given on almost all kinds of hives and frames. Address

KENNEDY & LEAHY,

EXCHANGE DEPARTMENT.

Notices will be inserted under this head at one-half our usual rates. All ads intended for this department must not exceed 5 lines, and you must say you want your ad. in this department, or we will not be responsible for any error.

WANTED.—To exchange circular-saw machine for hive-making machine for making dove-tailed sections, light saw-mandrels, or bee-supplies, for extracted honey. Clover and basswood preferred. 24d D. S. HALL, South Cabot, Vt.

WANTED.—To exchange one-half bushel of extra fine white-clover seed for alsike-clover seed. 19tfdb M. A. GILL, Viola, Rich'd Co., Wis.

WANTED.—To exchange 40 acres of good hammock land on Manatee River, Florida, suitable for all tropical fruits, sugar-cane, vegetables, etc., for Italian bees; good bee country, no apiary within miles. Address F. SCHINDEL, 23-24d Fort Ogden, Man. Co., Fla.

WANTED.—To exchange supplies at low rates, for Partridge Cochins fowls. 24d W. K. LEWIS, Dry Ridge, Ky.

WANTED.—To exchange or sell. Friends, I have 15 pairs of the celebrated Bonney's stock of Brown Leghorns that I will sell at \$3.00 per pair, or will exchange for good beeswax at 25 cts. per pound. Circulars free. Ref., A. I. Root. 24tfdb A. H. DUFF, Creighton, Guern. Co., O.

WANTED.—To exchange, Scott's Commentary on the Holy Bible, 6 vols., quarto, bound in sheep, in good order, weight 19 pounds. As I have other commentaries, I will exchange this for something else useful. Address A. H. VAN DOREN, 24tfdb Liberty, Bedford Co., Virginia.

WANTED.—To exchange golden-willow cuttings for Italian queens. I will book orders now, and send the willows as early as will do next spring; queens wanted in May and June, 1885. 2 dozen cuttings for a warranted, and 4 dozen for a tested; also one weeping-willow cut with each dozen. Will send by mail. S. C. FREDERICK, 24, 5db Coal Vale, Craw. Co., Kan.

FOR SALE.—or will exchange for choice extracted honey, very fine Wyandotte cocks or cockerels (Houdlette's strain, Wellesley, Mass.), and my strain Houdans, crows or layers. It would be difficult to buy better birds, I think. J. EVANS, 23-24 Schaghticoke, Renns. Co., N. Y.

A BARGAIN.—10,000 FIRST-CLASS ONE-PIECE SECTIONS, 4 1/4 x 1 1/4, for sale in lots of 1000 or more at \$4.00 per M. (This ad. will appear but once.) Address 24d J. B. McCORMICK, Fredericksburg, Wayne Co., O.

HONEY COLUMN.

CITY MARKETS.

CINCINNATI.—Honey.—Honey market dull; no change in prices. CHAS. F. MUTH, S. E. Cor. Freeman and Central Avenues, Dec. 11, 1885. Cincinnati, O.

BOSTON.—Honey.—Best 1-pound sections, 14@16; best 2-pound sections, 12@14. Slow sale. No demand for extracted. BLAKE & RIPLEY, Dec. 12, 1885. 57 Chatham St., Boston, Mass.

CHICAGO.—Honey.—The demand is quite good for the best grades of honey, when in nice shape; 16 c. is about the market for 1-lb. sections; 14@15 c. for 1 1/4 to 2 lb. sections. Extracted honey in fair demand, 6@8 c. *Beeswax*, 20@26. R. A. BERNETT, Dec. 10, 1885. 161 S. Water St., Chicago, Ill.

CLEVELAND.—Honey.—There is a little better feeling, and best white 1-pound sections sell at 15 cts.; 2 pounds, rather slow at 13@14; second quality, and old, are very dull at 10@12. Extracted, 7@8. *Beeswax*, scarce at 22@25. A. C. KENDEL, Dec. 11, 1885. 115 Ontario St., Cleveland, O.

MILWAUKEE.—Honey.—The demand for choice white-clover section honey is very fair, and the supply not large. Dark honey is neglected and slow; can encourage shipments of white-clover, comb, in 1-lb. sections. Can quote white 1-lb. sections, 15@16c; dark colored, 12 1/2@14c; extracted in bbls. and kegs, 7@8c. *Beeswax*, 25@28c, choice yellow. Dec. 12, 1885. A. V. BISHOP, 112 W. Water St., Milwaukee, Wis.

FOR SALE.

One second-hand fdn. mill that will roll sheets 14 inches wide. The mill is at present in New Hamburg, Ont., Can. The original price on it was \$40.00, but we will now sell it at half price, or \$20.00.

HONEY AND BEESWAX.

We are now in the market, and will be during the entire season, for all honey offered us, in any quantity, shape, or condition, just so it is pure. We will sell on commission, charging 5 per cent; or if a sample is sent us, we will make the best cash offer the general market will afford. We will handle beeswax the same way, and can furnish bee-men in quantities, crude or refined, at lowest market prices. Our junior member in this department, Mr. Jerome Twichell, has full charge, which insures prompt and careful attention in all its details.

Sample of comb honey must be a full case, representing a fair average of the lot. On such sample we will make prompt returns, whether we buy or not.

CLEMONS, CLOON & CO.,
Kansas City, Mo.

EXTRACTED HONEY,

16 TO 20 CENTS PER POUND.

The Canteen honey-package is so funny, everybody wants to eat from it. Will sell like hot-cakes during holidays and all winter. Samples of 5 and 10 cent packages, filled with honey, sent by mail prepaid for 25 cents. Send for price list and full description, and set your honey booming. Address

VANDERVORT COMB FOUNDATION MILLS.

Send for samples and reduced price list.

JNO. VANDERVORT, Laceyville, Pa.

BLACK JAVA COCKERELS.

A few fine birds for sale at \$3.00 each. Warranted to be as good as the best. 23,24,1,2d.

S. M. DARRAH, Chenoa, Ills.

Wanted. Situation with some bee-keeper. Have had three years' experience.

W. C. WRIGHT, Reagan, Falls Co., Tex.

Vol. XIII.

DEC. 15, 1885.

No. 24.

TERMS: \$1.00 PER ANNUM, IN ADVANCE; 2 Copies for \$1.90; 3 for \$2.75; 5 for \$4.00, 10 or more, 75 cts. each. Single Number, 10 cts. Additions to clubs may be made at club rates. Above are all to be sent to ONE POSTOFFICE.

Established in 1873.

PUBLISHED SEMI-MONTHLY BY
A. I. ROOT, MEDINA, OHIO.

Clubs to different postoffices, NOT LESS than 10 cts. each. Sent postpaid, in the U. S. and Canada. To all other countries of the Universal Postal Union, 10c per year extra. To all countries NOT of the U. P. U., 42c per year extra.

OUR OWN APIARY.

OR, RATHER, THE TEMPERATURE OF MOTHER EARTH; SUB-EARTH VENTILATION.

MR. G. M. DOOLITTLE touches upon a point that is of considerable interest to me; namely, the temperature of Mother Earth. He calls in question whether 55°, as deduced from Mammoth Cave, is true of all other localities (see page 856). I accordingly consulted a number of philosophies, physical geographies, cyclopedias, and other works that might bear upon the subject. None of these touched upon the particular point in question, and I then came to the conclusion that the temperature of Mother Earth is a relative term which is not uniform in all localities. However, I found that the temperature of artesian wells, to a depth of 2000 feet, is nearly uniform, with one or two exceptions. This temperature at this depth is about 80°; and one artesian well, in Paris, I think, is used for heating purposes.

After searching in vain in the various works treating on the subject, for the temperature of the earth within a few feet of the surface, I determined to institute a series of experiments myself, and, if nothing more, ascertain the temperature of the earth in Medina. Under our bee-hive factory is a well. The lifting-pump to said well will force a stream of water higher than the factory, and, of course, it would take but a second or two for the water to come from the bottom of the well to the surface of the ground. In consequence, the temperature of the water would be of about the same temperature as the ground at a depth of 97 feet. After the pump had been running about two hours, the piping and the pump itself would become of the same temperature as the water. When the

pump had been thus running we turned a jet of the water, right from the bottom of the well, into a pail. Into this I plunged a good thermometer. On remaining there a few minutes the mercury showed 56°. To be more sure, another thermometer of different make was tried, with the same result.

There is another well in the factory, used for drinking purposes, whose depth is 30 feet. After pumping perhaps half a barrel of water from this I tested the water as before, with two thermometers, and the result showed 57°. I would say, that this well is entirely inside the factory, and covered with flagging-stone, so that the temperature outside can not affect it. Thus it will be observed, that the temperature of Mother Earth under our factory very nearly tallies with that of Mammoth Cave, which is 55°.

I next tested the water of our cistern at home. After pumping out considerable water as before, and testing, the mercury showed 49°. The cistern is pretty closely covered, but I presume enough frost went down through the open chain-pump to sink the temperature five or six degrees.

In Cleveland last year, during the severe winter, the water-pipes, in some cases to the depth of 4 or 5 ft., froze solid. This being the case, I should suppose that, under ordinary winter weather, the sub-earth ventilator, being placed to a depth of 3 or 4 feet, would not give a temperature much above the freezing-point; and in order to get any thing like 45 degrees of heat we should want our ventilators placed at a depth of 8 feet, as some have recommended. To get 55 degrees of heat we must go to a depth of at least 40 feet, and probably more. This might not be true of all places, but I feel quite sure it would be of Medina.

I have shown that the temperature of Mother

Earth at Medina is very nearly that of Mammoth Cave; but in order to get at the temperature here, we must go down 40 feet or more. The well Mr. Doolittle mentions must be very cold — only 11° above the freezing-point in summer. Is this true of other wells in the same locality?

Now, I should like to know how nearly uniform the temperature is in other places, at a depth of 50, 75, or 100 feet. If we are to advise sub-earth ventilators for bee-keepers and others, it is important to know whether this advice is to be taken generally, or applied only to particular localities.

BOTTLING UP HONEY FOR MARKET.

Perhaps some of the friends are aware that we are bottling some of that carload of California honey in the 5-oz. Muth jars. These jars are to be sold to Butler Bros., of New York, as a neat ten-cent article of honey for their counter trade. A day or so ago I noticed one of our men, while putting up this honey, using an implement like the one figured below. The corks to the jars were too large for the mouths of the bottles, and, in consequence, they had to be compressed by some means until they fitted. The implement as shown in the cut will explain itself. You observe that we grasp the handles with the right hand, much in the way we do a nut-cracker. Next, with the cork in the left hand place it in the hole as shown; then while twirling the cork around so as to have it uniform, press upon the

CORK-PRESSER.

handles with the right hand. You notice that there is nothing particularly new in this device; in fact, it is the same thing that druggists use, only this is a home-made implement that any one can make. It is constructed as follows:

Procure a piece of wood (hard wood preferred), 2×3 by about 18 inches long. Near one end bore an inch hole half through. On the other side bore a similar 1½-inch hole, suited for larger corks. Next rip the piece through the middle of the strip with a rip hand-saw, in such a way as to cut the holes in halves. Fasten the ends near the holes with a common door-hinge; the other ends, whittle off for the handles. The implement is now complete, and operates like a nut-cracker. The cut shows the position of the holes after the piece is ripped. You can now fit corks to your honey-jars as well as the druggist, and the whole expense is but a trifle.

ERNEST R. ROOT.

REVERSING DEVICES.

SHALL WE USE REVERSIBLE HIVES OR REVERSIBLE FRAMES.

IN your reply to the article entitled, "Reversing the Hives instead of the Frames," page 771, Nov. GLEANINGS, you suggest that we "go a little further and have frames made without any projections at all to the top bars, in order that the frames may be lifted out when the hive is turned over." Now, if this were done, or even could be done without the grave difficulties alluded to, where would reversing the hive come in? However, we confess that we have lost some sleep trying to get rid of a small piece of the top bar of said frames, that seemed to stick out very prominently

at times, and be in the way, while at so many other times they were "such a handy thing to have about," as Toodles remarked about a second-hand coffin he had purchased. Still, notwithstanding all this, we have never been able to get along, as yet, without the nice little projection at the ends of the frames, and they must be at the top at that. If you are very anxious to have a frame such as you mention, you will have to get after friend Benton again (see page 552, Aug. 15, 1885). May be he can help you out of the difficulty.

We have figured it out in our own minds, that his reversible frame is certainly long enough to just fit inside of the hive, and slide down flush with the end, resting upon strips attached to the bottom of the hive in such a manner as to support the frames and preserve the proper distance from the bottom-board. Whether this is the way it is done, or, if so, whether it is practical or not, remains to be seen. Nevertheless, one thing remains certain; viz.: the necessity and utility of reversing frames at the proper time, and for certain purposes, seems now to be generally conceded. The bee-keeping friends are ready for it, and the great question to determine is, not whether we shall reverse our frames or not, but, how shall it be done, at the least trouble, by the quickest method, and at the least expense? Shall it be done by reversing the frames alone and singly, or by reversing the hives, and by this means turning all the frames at one operation? Now, since this matter of reversing the hives, being still in its infancy, has not been as fully brought out as reversible frames, nor perhaps as well understood, and because you, friend R., started the ball to rolling when you told us about reversing the Simplicity, let us fully investigate its claims, pro and con; and if there is nothing in it, of course it will turn out differently from "Banquo's ghost."

Now, in order to bring out the matter in the clearest light, let us suppose a case in practice. If reversible frames should be decided upon, by some one owning an apiary of 50 to 100 colonies in ten-frame hives, and the bees all were comfortably installed on movable frames having the regular orthodox projecting top-bars, in order to convert them into reversible ones, the necessity would arise of purchasing or manufacturing 1000 to 2000 reversing devices; the removal of 500 to 1000 frames of comb from the bees, a few at a time, to a place suited to work at them; the sawing or cutting off of 1000 to 2000 projections, together with the fitting and attaching of the same number of said devices, and then returning them to their proper places! Now, the question is, Would this be a very easy and practical undertaking at any other time than early spring, or even then would it pay for the expense and trouble? Who has done it? On the other hand, suppose he should adopt reversible hives instead of reversible frames, to accomplish said purpose. How proceed? We answer, first have ready a few reversible hives to commence the work with. This can be done by fixing over hives that are on hand and empty, making them reversible; or if none are on hand, making all the new ones on the new plan that are going to be needed, then proceed to set a colony in each one, then fix over those thus emptied, and so on, until all are completed.

Now for the questions. How easy is this plan? how practical? how expensive? how much better than the other method? We will presume to answer as follows: Very much easier; much more practi-

cal; a great deal less expensive; and, in our opinion, as good, if not better, save in the one instance of not allowing the frames to be removed while the hive is turned over until it is turned back again. We do not presume to know how much of an objection this would be to the average bee-keeper, or whether any, but are inclined to think that it would all depend upon how often occur the necessity and occasion for removal at the particular time the hive is thus reversed. It is not presumed that the hive shall be turned up very long at a time, if we thoroughly understand for what purpose and when it should be done.

Now as to the question, Can our hives that we now have in use be easily altered to be reversible ones? We think that the most of the kinds in use can be, and at very little trouble and expense. We remodeled about 80 this spring. HEMPHILL & GOODMAN.

Elsbury, Mo.

A PLEASANT REMINISCENCE OF CHILDHOOD DAYS.

A SAMPLE OF A BOX-HIVE MAN.

FRIEND ROOT:—Our first business transaction dates Jan. 11th, 1883. In connection with business as one of your Western customers, you will probably know the name. As I have as yet obtained no great distinction among men as an apiarist, or any other vocation, you may consider my scribbling of little consequence, and lay it aside, or consign it to the waste-basket. Be this as it may, I will proceed to give an account of myself, and the progress made in our "chosen pursuit" throughout my locality.

My father was a bee-man before me, hence you can throw the mantle of charity over me, if I appear too enthusiastic. He emanated from Kentucky soil, and pitched his tent in the exact locality of the writer, in the spring of 1828. Civilization was then battling with the red man and wild beasts of the forest. Settlements were very sparse, and those twenty miles distant were considered neighbors.

Within a dozen rods of our present residence is the site of the old log cabin. Two little mounds are all that remain to mark the location. The two mud-and-stick chimneys that have long since fallen to decay leave the only monuments to the memory of the pioneer days of our parents. How my memory reverts to the many incidents related by my parents, while they were occupants of this rude domicile, of how the wolves howled, panthers screamed, night-owls screeched, and many unaccountable noises made nights hideous! how they had to make tight coverings over their pigs, to prevent "varmints" from carrying them off; how, within an hour or two hunt, they could secure the best of venison and wild turkey; and frequently within a stone's throw of the cabin; how they lived for months on venison, hominy, and wild honey, with an occasional abridgement of johnny cake and sassafras tea.

It was in those days that we might date the dawn of bee culture on the Hambaugh homestead. Captured in the wilds of the forest, and with the proverbial "log gum" prepared, the increase soon brought its reward, and a primitive apiary was the result. Under the supervision of my father the bees were a source of considerable revenue. Being

a man of strong constitution and indomitable energy, the surrounding forests gradually gave way to fields of waving grain. The old log cabin was eventually superseded by a large residence; and ere his death the "iron horse" was traveling through his possessions, and the landscape was transformed into a beautiful panorama. The onward progress of civilization had worked wonders, and none were so well calculated to realize it as those who had endured the drawbacks and privations of early pioneers.

Never has the old homestead been entirely destitute of the busy bee. The "hum" used to gladden the heart of my father; and though the modes of management were those of the primitive days, he took great pride in them, and many a barrel and keg of strained and "mush" honey has been sent to market. Within my own recollection I have seen old-fashioned "log gums," that would require three or four men to handle, carried from the brimstone-pit to the old house, where its contents were disposed of. The harvest, which took place the first cold weather in winter, usually lasted a week or ten days, and the wax was by no means a small factor in the enterprise. An old resident in our neighborhood states that he paid for eighty acres of land with money obtained from beeswax alone.

It was always a source of pleasure for me to assist my father with his bees; and as he grew old, the care of them gradually fell to me; as the bees were considered a matter of minor importance, no special pains were taken, other than to have plenty of "gums" in readiness for the swarms, and when they issued, hive them, place them in a fence-corner, and let them go till the harvest came around, then what the moth-miller had not destroyed we would confiscate, except sufficient for the next year's increase.

It was about four years ago that I took my first step forward in the art of bee culture, and I must confess it was a very short one. I took no broader view of the art than to follow those of my own knowledge who were the pronounced bee-men. An elderly gentleman of our county, by the name of Walsh, was the pronounced bee oracle, and I partook freely of his instructions, which were something of this order: "You are bound to give the bees room for their surplus fat, the natural accumulations from the under part of the abdomen"—a terrible dagger to comb foundation. He says the extractor is a humbug, and has done more to degrade the honey market than any other one thing, and ought to be abolished. He is also adverse to the use of sections for surplus honey. He also states the Italian bee is far inferior to our native blacks, and are fit for nothing but to rob, pilage, and sting. He says father Langstroth is a humbug; that the movable-frame hive was in use a century before him. He laughs at the idea of building up weak colonies with brood from the strong, to avoid moth. He has been puzzling his brains for years over an effectual moth-trap, which he claims to have perfected, and a queer device, too complicated to describe, can be seen under every one of his hives. He says that nectar does not emanate from flowers, but from the elements, and falls like dew; and, were there no flowers, bees would gather honey from church-steeple and house-tops. I could relate many other cranky notions of this respected gentleman, but this will suffice to show how far some can wander who will not

accept of any standard works or bee-masters as superior to their own frail and crooked ideas.

This man was my tutor for one year, and I was foolish enough to use a few of his hives, and, of course, you can believe my first step a short one in advanced bee culture; and up to this time I had never seen the inside of a bee-book. I had often heard of Langstroth's work, and was anxious to learn something of the hidden mysteries of the bee-hive. I chanced to receive a sample copy of the *Farm Journal*, in which I found an advertisement from A. I. Root, asking all who were interested in bees to send him their names. I complied, and received your catalogue in return, and it was but a short time ere the ABC was at hand. With this able work I felt a new impetus, and, with the addition of Cook's Manual and Dzierzon's work, I flattered myself as making broad strides in the right direction. The old hive was soon superseded by the eight-frame Langstroth hive, and, still later, all have been transferred to ten-frame Simplicity hives, where they are going to stay.

In connection with what I have gained from our leading bee-periodicals and standard works on bee culture, I have visited several apiarists of note, chief among which are the old pioneers in the profession, Chas. Dadant & Son, to whom I am indebted for willing and wise counsel. Long may they live! I have prolonged my remarks further than intended, and I fear trespassing on your valuable space.

Springs, Ill., Nov. 25, 1885. J. M. HAMBAUGH.

QUEEN-CELLS.

LARVÆ, AND THEIR DEVELOPMENT.

FOR some time we have been trying to get a good cut of queen-cells and brood for our ABC book; and after several trials our engravers have at last succeeded. The veterans will recognize the different cells as shown below.

QUEEN-CELLS AND LARVÆ.

D, whose surface is smooth, and does not show the usual network, contains only a drone-larva, instead of a young queen. A is a queen-cell just started; B is a cell further on in its stage of development. C is a cell from which a queen is just hatched, and to which the little hinged cap still adheres. E shows a cell that has been torn open by a young queen. This opening shows evidence that the bees had assisted her after she had made a small hole. In this connection I would say, that when tearing

down unnecessary cells I rarely take the trouble to destroy them wholly, and hence I merely pierce a small hole with the knife or a straw, and leave the bees to do the rest. F shows the grubs, or larvæ, and which are seen scattered in various places. Below A is sealed brood, and here and there young bees just gnawing out. These young bees are not so good as the rest of the engraving.

While upon this subject I shall give a brief review of the development of the larvæ, as set forth in the admirable work of Frank Cheshire. Huber, Réaumur, and others, claim that the grub does not change its skin in the process of development. Cheshire claims that this assertion is a mistake; that the skin is non-elastic, and that in a short time, becoming bad fitting, it bursts, and is cast off. In like manner this is replaced by a new skin, and so on to the probable number of five.

This was a new idea to me. On consulting the authorities on the silkworm I found that it also casts off a number of skins. As the silkworm is the larva of the moth, if we reason from analogy we are led to suppose that the larva of the bee may cast off its skin also. Frank Cheshire states that a careful investigation will show the ruptured pellicles in the bottom of the cells; however, with my Coddington lens, Boush & Lomb instrument, and dissecting-tools, I failed to discover more than one pellicle. Perhaps I am not skillful enough; but because I do not succeed in finding them I am not prepared to say they are not there. Briefly, then, the development of the larvæ as given by him, is this:

The grub, after casting off its several skins, packs them in the bottom of the cell, together with the excrement given off by the grub. The last pellicle it packs around the cell, and then completes the inclosure with its silken web. This leaves the cell nice and clean, and the grub has now only to grow. Microscopical examination shows that this case, cocoon, or whatever we may call it, is not a mass of fibers, as we might expect, if it were simply the web of the larva. On the contrary, it has the appearance of a skin, or pellicle, of the worm. Had it not been winter weather after procuring a larva from the hive, I would have skinned him and compared this with the lining of the cell. If the microscope showed they were identical in appearance, I should be compelled to believe that Mr. Cheshire is correct.

When the weather permits I will push this matter a little further. If good authorities have been mistaken for so long, it is time we put ourselves to rights.

ERNEST R. ROOT.

WINTERING IN THE SOUTH NOT SO EASY.

LEAVES FOR PACKING.

FRIEND ROOT:—Though this is a rather late day to send in my report for last winter, I should like some of the veterans who have lost so heavily to know how a novice has succeeded in the all-important subject of wintering. Fall count, 18—17 strong, 1 weak (a cluster covering only 4 frames). The 17 colonies had from 30 to 50 lbs. of honey each, just such as they had gathered from the field. The weak one was fed up on unfinished sections, after frost had fallen. Spring count showed that I had not lost a colony, although one-half of them were weak, caused from

dysentery. Eight of my colonies had a quilt, made of a common corn-sack that cost only 6½ cts. each, over the frames, and without an exception they came through clean and dry, not a sign of dysentery; even the colony with only four frames came out all right. The remaining ten colonies had a honey-board on; and, with two exceptions, they had dysentery badly. The upper story of each hive was packed with forest leaves, as suggested by J. E. Pond, Jr.

Many may think that it is a very simple matter to winter bees as far south as this; but when I tell you that from one-third to three-fourths of each apiary was lost the past winter in this county, you will not think it such a simple thing to winter successfully. The tropics are away south of here, for we had plenty of zero weather last winter. From 6 to 14 degrees below was not unusual. Pollen was abundant in every hive; but I am of the opinion that it would have been better had there not been so much of it present. My bees were left on summer stands, with a wind-break of cornstalks about 6 feet high to protect them from the north winds.

Now, friend Root, I should like to have you tell me when is the best time to move bees; also how to prepare them for shipment. Don't you think in March or April would be the best time? I shall move from here to Bowling Green, Ky. You remember the place, of course, as you passed through it on your way to the World's Exposition. Your description of the cave was very interesting, and, strange as it may seem to you, although I have lived within 30 miles of the great wonder all my life nearly, I was never in it. We are apt to care very little for wonders near us. E. W. STATTON.
Martin, Tenn.

Thanks, friend S., for your kind letter. The subject of moving bees is so fully discussed in the A B C book that it would hardly be advisable to go over it here. I think March or April would probably be the best time. We should try to avoid either extreme—very hot or very cold.

REPORTS ENCOURAGING.

FROM 25 TO 50, AND ABOUT 13,000 LBS. OF HONEY.

MARCH 1, 1885, found me with 25 colonies of bees—two-thirds Italians, one-third black. I increased by natural swarming to 50. By May 1st I stopped all swarming by extracting and cutting queen-cells after above date. I finished extracting to-day, November 10th. I had 1000 gallons of honey, all extracted from top story, the bees having their winter supply since June, in lower story of 10 frames, from basswood. I bought a new belt, and shall wear it until somebody does better. Let him report, and I will send said belt by first mail. JOHN W. ROSS.
Velasco, Brazoria Co., Tex., Nov. 10, 1885.

Why, friend R., your report is a tremendous one. Estimating 11 lbs. of honey to the gallon, we find you received about 260 lbs. on an average from each of your original 25. Good for Texas!

BEES PAY LIKE OTHER STOCK.

My report for this year is not large, yet every year convinces me that bees can be made to pay as well as any other stock on the farm; and as to

the sale of the honey, when put up in good shape, it will sell about as well as butter. Spring count, 17; increased to 35; good condition; comb honey, 600 lbs.; extracted honey, 600 lbs.; all, 1200 lbs. Sold 700 lbs., nearly all at home. O. S. DUGBY.
Kingsville, Ashtabula Co., Ohio.

FROM 14 TO 26, AND SOLD \$90.00 WORTH OF BEES AND HONEY.

Last spring I lost my entire apiary of 66 colonies, fall count, except one queen and about a teacupful of bees, which, by careful nursing, I built up to a good strong colony during the season. I sent to friend Foster for 14 nuclei, which I built up to good colonies, and increased during the season to 26 good strong stocks. We got no surplus here till about the last week in August, then we had a nice little honey-flow of some three weeks. The result of my summer's work foots up thus: 14 nuclei increased to 26, all in good condition for winter; sold \$50.00 worth of bees, and have \$40.00 worth of fine thick honey. While this is nothing to boast of, still I am satisfied, all things taken into consideration.

J. W. MARGRAVE.

Hiawatha, Kansas, Dec. 4, 1885.

"IF AT FIRST YOU DON'T SUCCEED, TRY AGAIN."

I have been a reader of your paper for several years. Though I have been in the bee business only two years, I will give you my report for the past season, but it will hardly be fair to give it and say nothing of last year's work.

I came here from Ohio in April, 1884; bought 50 colonies at \$5.00 per colony; increased to 65, and took 800 lbs. of honey; purchased 14 more in the fall, at \$3.00 per colony, making 79 in all. A great part of their stores was honey-dew. About all survived the winter; but spring dwindling set in, and left only 47, 4 of them queenless, and most of the others weak; but by feeding and extra care, I got them into fair condition. By the commencement of the white-clover flow they increased to 84, and took 3700 lbs. honey—1400 extracted, 2300 comb. I have sold, up to the present time, \$420 worth, and have on hand \$60.00 worth. I have tried Heddon's plan for preventing second swarms, and I succeeded very well. I have also used his crates, but prefer a modification, and a plain honey-board, making the bee-space in the bottom of the crate instead of in the honey-board.

Beginners can save money by making chaff cushions out of burlap, such as yarn, cotton batting, etc., are shipped in. I get it of the dry-goods merchants, and the material for my cushions costs less than a cent each.

I find gloves acceptable occasionally, in the fall, while handling cross hybrids, and have a pair made of firm brown ducking, with openings for my fingers to extend through, nearly to the second joint. The bees will not sting it as they do buckskin. Our sources of honey here are the old reliable white clover; and for fall supply, the Spanish needle, which grows abundantly here in the bottoms, sloughs, and low ground, and yields a rich yellow honey, resembling poplar honey in appearance and flavor.

Bees are plentiful here, and I have been surprised at the amount of honey brought in here for sale from old box hives, which speaks well for the country as a honey section.

B. A. RAPP.

Chillicothe, Mo., Dec. 6, 1885.

AN AVERAGE OF 75 LBS. OF HONEY PER COLONY.

I commenced the winter of 1884 with 30 swarms; 2 starved—the first I have lost in wintering for five years. I commenced this season with 28; have taken about 1600 lbs. in sections, 500 lbs. with extractor—an average of 75 lbs. I have now 41 swarms, after doubling back. Best yield, about 175 lbs. in sections, 25 extracted; lightest, 50 lbs. in sections. I winter one-half in chaff hives on summer stands, the rest in cellar.

C. H. BOYD.

North Monroe, Waldo Co., Me., Dec. 7, 1885.

REPORTS DISCOURAGING.

100 HIVES, AND NOT ENOUGH TO WINTER ON.

I HAVE 104 hives of bees; had about 100 in the spring. They haven't gathered enough to winter on. I have fed them about 500 lbs., and will have to feed about 200 more in the spring, so you see that it is all loss this season. The hard cold winter in the spring, and the dry weather, killed the clover; buckwheat was not very good.

Amity, N. Y., Dec. 4, 1885.

J. W. UTTER.

DISCOURAGING TO A NEW BEGINNER.

My expectations in the bee-business have utterly failed. I shall not get over 10 or 15 lbs. of box honey, from 16 hives. What do you suppose is the reason they did not make any more honey? I had buckwheat, and a great variety of flowers, besides quite a lot of the spider plant all around our place, besides being right alongside the woods. My honey so far has cost me about \$5.00 per lb. Of course, the brood-chamber has all they will need for winter and brood-rearing; but from the account of so many bee-men, about bees filling the hive and turning off such quantities of honey in one season, it looks (after my first season's experience) rather dubious.

I got, in the spring, 6 box hives, and increased to 17 (one dwindled or died), and I now have 16 hives of bees, and took honey from only two of them, and I am out about \$60.00 on the bee-business. This does not look very flattering, does it? Still, I expect to increase them until I get 100 colonies or more, if I can possibly raise the money to buy the Simplicity hives, for I don't like any other.

R. J. WATERS.

New Madrid, Mo., Nov. 2, 1885.

FALSE STATEMENTS IN REGARD TO THE HONEY BUSINESS OF OUR COUNTRY.

As a protection to our bee-keeping population, we propose in this department to publish the names of newspapers that persist in publishing false statements in regard to the purity of honey which we as bee-keepers put on the market.

THE following I copied from the editorial department of the New York Weekly *Witness*, issue of Sept. 3, 1885, page 6:

"Honey has become so adulterated now that there is no pleasure to the fastidious in eating it, as you do not know whether you are eating a mixture of glucose and honey, or the pure unadulterated article. Virgin honey in the comb, as manufactured by the bees, is most delicious; but nowadays the bees are saved the trouble of making the comb, and a manufactured article is put in for them to fill with honey, and you do not know in eating it whether you are eating bee-made comb or man-made comb, a tough and indigestible mass. Let us have pure honey, Mr. Bee-keeper!

It is a reply to L. Starr, Mallory, N. Y., an intelligent bee-keeper, if I mistake not. Mr. Starr is probably not a reader of GLEANINGS, or he would, or should, have sent you this item himself, together with his own letter in the *Witness*.

The above, considering the source, and the position as a Christian teacher of the author, may justly be styled "a pious fraud."

JOHN D. GEHRING.

Park College, Mo., Dec. 4, 1885.

Thanks, friend G., for kindly calling our attention to this matter. It does seem to me really awful, to see papers like the *Witness* listening to sensational newspaper canards until they lose their own senses. Now, dear friends of the *Witness*, will you not be kind enough to as publicly correct the false impressions you have given, and admit that you were mistaken? My offer of \$1000 is still open, to any newspaper editor, or anybody else, who will tell us where comb honey is manufactured without the agency of bees. I appeal to you as Christian men to make a little reparation for the injury you have done a class of honest and hard-working people. You have GLEANINGS as an exchange; and by reading the numbers for a few months back, especially the articles under the department that heads this, you can see how hard we have been laboring to get even simple justice. No one should buy honey without seeing that the name of the producer is on the package; and if you do this, I am sure you will not get either liquid honey nor comb honey that is a fraud. This quotation from the *Witness* is the one referred to on p. 647, Sept. 15.

The following is clipped from the *American Analyst*:

HONEY.—You are correct about the prevalence of adulterated honey. Comparatively little of the article bearing that name sold in retail stores is genuine, even the wax cells being often skillfully and fraudulently imitated. We noticed in the last number of the *London Analyst* that a correspondent warns analytical chemists against American honeys, which he says are being adulterated with a syrup manufactured with maize, the method being kept secret. His own experience shows, however, that if wheat or maize starch (not potato starch) be treated with oxalic acid or any other powerful organic acid, a syrup is produced, which, in a certain concentration, and after standing two or three weeks, exactly resembles, in taste and appearance, an old honey. It seems a shame to cheat the busy bee out of the reward of his patient industry.

If any journal should be truthful and reliable in matters of this kind, it seems to me that one with such a name as the above paper, hailing from 176 Broadway, New York, ought to be that one. Now, friends of the *American Analyst*, we call upon you to correct your unwise and very positive statement. If anybody in the world ought to be careful what he says, it is an editor; and for an editor of a scientific paper to thus help on a fraud is lamentable. Will you not please add, friends, that it is a mistake, and that you were misinformed? If you think there is such a place, where wax cells are imitated, as you say, just hunt it up, and your \$1000 which we offered last month is ready now. Yes, it is now \$1500. You will please prove you were right, or else take back what you said.

MORE ABOUT HONESTY AND HONEST WARES.

STRICT BUSINESS PRINCIPLES.

THANK you, friend Root, for the credit you give me, of both kinds, for my last article, Oct. 15. Bless your heart, I should like to give you a great deal more of the same kind, if you can have patience with me. I meant to add, that Mr. Wright said he must make the mistake concerning that honey "right with the old fellow," and I have no doubt he did. I can generally tell by the way a man says such a thing whether he means it or not. Can't you?

Mr. E. went to a shoe-shop to get his boots mended. Mr. D., the cobbler, had not been long settled in M., and he was not acquainted with E., neither did he know Jim S. as well as his neighbors did, until he had lately found him out. E. wanted Mr. D. to mend his boots, and E. would bring him wood in payment. Mr. D. said he would take the wood, but he would have to have it before he did the work. E. was rather taken down, for he had never been taken up that way before. Mr. D. explained that he had done some work for Jim S. on such an agreement, but the wood had never come, and he could not afford to run another such risk. E. replied, "I do not blame you. But I will give you a load if you will go out and find one man who will not tell you that I will bring you the wood if I promise to."

At this juncture Mr. B. stepped into the shop, and E. stated the case.

"You mend his boots," said Mr. B.; "and-if he does not bring you the wood I will pay you for it." Mr. D. mended the boots, and E. hauled him the wood. Who would you or I rather be—E. or Jim S.? Why, bless you, E. possessed what was worth more than any \$30,000 that Jim S. might gain—a good name.

It is not every man who would scorn to tell a lie for a thousand dollars—who would feel insulted if offered a bribe—who is clear of little, petty, secret deceptions. It is the subtle form in which temptations often come that constitutes their chief danger. Many men who regard themselves as quite honest will cheat in a horse-trade by failing to mention some little blemish, or will, if a man pays him a little too much change, keep it. "He made the mistake; let him learn to be careful." Such things seem to me very dishonest. In no way is one more often tempted than to sell an article slightly inferior, for a good price. To produce a really first-class article at a high price, even at it, may be, some pecuniary loss, is a kind of honesty as worthy as any. Speaking of E. led me to the above thoughts. He has always sold his wood a little higher than any one else around here; yet there are a number who prefer to buy his wood. It is the same kind of timber, but is all of full length, well split; and he gives, as we often term it, "Methodist measure."

E. once made some railroad-ties for a horse-car road. One of the company said, as he examined them, "I have but one objection to them; that is, that the rest are not all as good as these." He did not make as much money as other contractors, perhaps, but he earned what was better. I repeat nearly what I said before: To produce a first-class article—an *honest* article, if you please, is to win a golden name—an honor which is as well earned, and may be as proudly worn, as any the world can

offer. It is a prize worth having, if nothing else is involved. I am far from estimating the value of a good name in dollars and cents alone. To be justly esteemed by others is a great boon: to be justly esteemed by myself is a greater one. On the contrary, to be dishonored by others is only better than to be dishonored by myself. All these things are involved in this matter.

I once went into a drug-store to get a glass of soda. While drinking, the druggist stepped into the back part of the store. Hidden from his view by the apparatus I could easily have stepped out; and when at length he came to receive the money I jocosely told him so.

"Oh! well, now, you wouldn't have done that. Why, you would have felt worse about it than I should."

I thought, "You are right, Mr. D.; I *should* have felt worse. And no matter what I might slip out of or slip into, if I should do such things I should know myself to be a slippery man, and others would know it, and I would to that extent lose the respect of myself and all true, honest men. I prefer to be honored and trusted by myself and others, at whatever sacrifice."

I once accidentally overheard a whispered remark concerning myself: "He is as honest as the day is long." I felt, not vain, but proud. If I am honest, I am amply repaid for it. I am a poor man, and discontented with my lot; but I would rather take poverty with honor, than the wealth of Jay Gould with all its attendant blessings, and the name he has acquired with it.

But I do say, that honesty in all things will pay pecuniarily. Rogues sometimes prosper more than any honest man can. But usually the reverse is the case. E. rejected a number of wood-choppers, to employ a man whom he knew would do a good job—a species of honesty. It paid that man to be thus honest. I know that the growing business of Mr. Wright, before mentioned, is very largely due to the fact that he is known to be trustworthy.

The propensity of some men to make false promises, or thoughtless promises, which they make no effort to fulfill, is very annoying. Either one is a kind of dishonesty—the former, a bad type of it. The one who practices such deceit is sure to lose the confidence of his customers; and to do that is to lose both reputation and business. I once wanted a job of nice work done at a planing-mill in S. I gave the order in the forenoon, and the material was promised by three o'clock. I got there a little after time, and, so far as I could tell, my order had not been yet touched. The boss came and told me that they did not have all the lumber necessary to fill the order, and had had to send for it before they could do the work, looking anxiously into the back room as he said it. Did you ever see a boy try to sneak out of a room with something under his coat that he wanted to hide? Well, that man talked just as such a boy would act. I believe that excuse was a pure fabrication. He could hardly see how to excuse himself, it appeared to me.

"How long before the stuff will be ready?" I asked.

"About fifteen minutes."

I went away, and returned in about half an hour, to find a man sawing at some boards that looked like mine; but surely mine were done. I looked at them and then at the boss, who said nothing until spoken to.

"Is my stuff done yet?" I asked.

"No; don't you see it is not?"

I felt insulted. How did I know that stuff was mine? I rather thought it was, for he said mine would be ready before that time. He felt mean or he would not have talked that way. I said nothing; but by keeping watch over him the stuff was ready in fifteen minutes. I intended never to patronize that man again, and I did not until I had hunted the city over and found that I could not get what I wanted anywhere else. I went back to him because I had to. I had to send after the stuff. He gave me more than he at first thought he could, he said, for the money. It came to me in a bundle; and when I unpacked it I found the raggedest lot of lumber I ever got. Such patching as I had to do! For some kinds of work the stuff could not have been used at all, and the boards were not as thin as I wanted them, or as they would have been if I had been there to watch him. To call such a man a liar and a cheat may seem harsh terms, but they are the simple truth. I think I shall send off for my stuff next time, even if I have to pay more for it.

I am not through yet, but I must stop. I expect this will go into the waste-basket, after all; but I can sell honest honey; I can keep my word; I can tell the truth, all the same, confident that in the long run honesty is the best policy.

GEO. F. ROBBINS.

Mechanicsburg, Ill., Nov. 25, 1885.

Friend R., I do think it pretty harsh to call even a bad man a liar; and if you will excuse the liberty, I am afraid you are a little inclined to uncharitableness. I used to think it was the right thing to do, to face a man and denounce him as a liar and cheat, when the circumstances seemed to warrant it; but for some little time lately I have decided that such a course so often does more harm than good, that I have resolved to be very careful about doing it any more. Further back you make the remark, that rogues sometimes prosper, etc. Now, if you have the correct definition of the word "prosper" in mind, I do not believe that rogues ever do prosper. They sometimes get money, but so does the highwayman; yet, would you want to stand in his shoes? Show up fraud and deceit unsparingly, but let us be mild and careful in our denunciations.

ARRANGEMENT AND POSITION OF THE STORES FOR WINTER.

A WINTER-NEST.

I READ, in the department of Our Own Apiary, in GLEANINGS for Nov. 1, the following: "It was just in this way that we wintered our bees last year with, however, the exception that they now have honey instead of sugar stores."

Now, I think I see another very important difference. Last winter, if I mistake not, you arranged your hives and then fed syrup. This allowed the bees to place their stores as they saw proper. This year your plan gives them no choice. I believe it essential to have what Mr. Doolittle calls a winter-nest; that is, a space containing no stores in the combs on which the bees cluster. I would rather have my bees separated by a division-board than by a solid frame of honey. I fear that your only chance of success this winter is that your bees may

have time to consume or remove the honey from this space before very cold weather. In our climate we often open hives through the winter, and always find them arranged with the winter-nest. If stores are sufficient, we do not average a loss of five per cent.

W. H. GREER.

Paris, Tenn., Nov. 24, 1885.

Friend G., I think it quite important that the bees have this winter-nest; that is, that the bees shall cluster together in the form of a sphere, in empty cells, and then that there should be food enough so it entirely surrounds them, above and below, to the right and left, in front and rear. Our most successful wintering has been when things were in this shape, and I admit that heavy feeding just before winter seems to get this state of affairs best. Our bees have such an abundance of natural stores, however, that the conditions are pretty nearly in this shape as it is. In our locality we never have too much honey in the hives for winter, because they have ample time after the honey-flow ceases, to consume enough to give them this brood-nest. In speaking of heavy feeding, I mean that, although you feed heavily, several days will be occupied giving enough for winter.

ANOTHER FLORIDA APIARY.

MISERY LOVES COMPANY.

SEEING reports in GLEANINGS from so many places, I am moved to write an account of my own apiary, even if I have come so near getting into Blasted Hopes. The article on page 774, by that California "bee lunatic" gave me some comfort. By the way, is it not rather curious, when a person is out of luck, feeling out of humor with his surroundings, and about half displeased with himself, how quickly it will raise his spirits to hear of somebody who has not done so well as he has? I have a notion to sermonize a little right now, instead of writing about bees, but I will curb the inclination, and just say, in that line, when you have the blues, and feel as if every thing were going wrong, and you might as well quit trying, or any feelings akin to those, stop, collect your thoughts a little, look around, and see how much better you fare than somebody else. More than likely you are faring much better than a majority of poor suffering humanity.

I commenced last year with 15 stands of Italian bees, which I brought from Iowa. They increased to 42, and we took 1650 lbs. of honey, nearly all extracted. I thought I had found it, and solved the problem how that hungry spell from a pine woods to a bearing orange-grove could be bridged over, at least for my family. But, alas! how uncertain are earthly things!

Last spring we started in with 40 stands. I had sold two, and left the 40 on their summer stands, with the upper stories on. They were in good condition, and commenced swarming in April. Dry weather set in about this time, stopping their supplies so they stopped swarming; and by middle of May there was less honey in the yard than when swarming commenced. It now set in wet, raining nearly every day for three months, very little honey could be stored, and only occasionally a new swarm came out. I was bothered a great deal by

loss of queens, some hives being supplied the second or third time, and, what I am most ashamed of, three colonies were lost by moths before I got them supplied. I might have saved them by timely care.

The moth is a terror here to native bee-keepers who have the common bee in old-fashioned hives; but it is a comfort to me to see how quickly the Italians will carry them out by the back of the neck, when I put a frame infested with them in the middle of an upper story of a populous hive. There is no trouble from the moth, with good management. As yet I have found no trouble with any other enemy.

We finished extracting for this year on the 18th, and find we have taken, all told, 1000 lbs. of honey; about 150 lbs. of this was comb honey, partly in sections. I found great difficulty in getting them to work in sections. They much preferred storing honey in comb already built. They sent out eight swarms, three of which flew away. One was doubled up with a queenless colony, leaving, after deducting for what was lost, an actual increase of one. The honey is worth about 11 cts. in this market; 1000 lbs. at \$110.00, one new colony \$6.00, \$116.00.

I am very thankful for this much, and am going on my way rejoicing, and expect to do better next year; and if I don't, I still expect to keep bees, for it has paid even this year.

This country is high dry pine land, no swamps or hammock land nearer than four miles, about as uninviting bee-pasture, it seems to be, as there is in Florida. It will be much better in a few years, when the 40,000 orange-trees within two miles of here are full of bloom. There are many kinds of flowers in the woods and fields, but I am puzzled to know where they get the great quantities of honey they stored sometimes last year.

I find a banana-plant makes a nice shade for bee-hives. One plant will shade two or three, by setting them at different points of the compass. The leaves die in the winter, letting the sun in when it is cool. When warm weather comes again, and shade is needed, it is ready, with its great broad leaves, to make a refreshing shade. There are many good points in Florida for the bee-keeper, besides where friend Hart lives. There are many of these places where the business is entirely undeveloped, and a little well-directed energy by men well posted will surely bring its reward. It is no small thing to be entirely clear of the work and loss connected with wintering, which our Northern bee-keepers are subject to. FRANCIS TRUEBLOOD.

Archer, Florida, Nov. 27, 1885.

A DISEASE OF THE BROOD THAT IS NOT FOUL BROOD.

DESICATED BROOD; ITS CAUSE AND CURE.

ON page 734, Nov. GLEANINGS, Mr. Dwight Furrer asks me to "give further light on the subject." The desicated foul brood that he refers to has two distinct types, or, as may be classed, a contagious and a non-contagious type — that is, so far as I can ascertain from all the investigation that I have been able to make through the seasons, beginning in 1878, up to the present fall. I have not known of a season since my first observation of the plague but that I have

been able to investigate several cases of either one or both phases of the disease.

The non-contagious type I have, to my full satisfaction, traced to a trouble of the queen, or an hereditary trouble from the drone mating, as I have found it only in the worker-brood; thus I concluded it was from the deficient vitality of the drone-sperm, as a constitutional weakness. I had once thought that it might be, as inferred by a recent contributor to the pages of GLEANINGS, a venereal disease; but as such diseases are copulatively contagious, I withheld such a decision. Finding the non-contagious type always in a locality where there were plenty of degenerate black or hybrid bees, and quite often it appeared in brood of a mis-mated Italian queen; therefore I attributed it to the drone mating, and I can not see any reason to not credit it to the devility of the drone sperm; and yet if the drone-brood had been affected in the same way there would not have been a chance to locate it on the vital weakness of the drone; therefore your decision of the change of the queen is a substantiation of my conclusion, and the successful practice shows the theory to be a true one in the case of the non-contagious type, and also the strongest proof to be obtained of the deficient vitality of the drone-sperm, which can be in part accounted for in two ways, as presenting itself through various observations that also bear on the subject of my article on page 732, same issue of GLEANINGS, concerning queens, and I will try to make it plain, as I see them, in an article at some future day.

THE CONTAGIOUS DESICATED FOUL BROOD I found to be contagious, and for three or four years I tried to obtain help from many prominent apiarists to find out something about it, and have never yet received one line of information, either pro or con, except in 1879, two letters from Mr. T. G. Newman, and I had given up all hope of any light from any one. I have kept on nursing two or three colonies for the past seven years, thinking I might yet find out all about it, and occasionally I find localities where it has wiped out a whole apiary; and by putting healthy stocks on to the same ground, the disease always showed itself the second season. That the disease was present, I have proved by the destruction of at least 50 colonies that I have used of my own for that purpose, and always taking them from perfectly healthy localities so far as I could learn, and using new hives and virgin combs built on foundation as thoroughly clarified as I knew how to do it.

Another curious fact is, that a thorough scouring of hives and frames and fixtures with strong salt and water, just wiped out all contagion when the contagious desication has developed into a genuine, rotten, stinking mass of the capped brood when carried into strong healthy stocks at mid-summer, and proves that the caution given, page 504, A. B. J., 1883, was not without reason.

The two phases are so similar in early stages, that the novice would not notice the difference. First an occasional grub, when nearly ready to cap, will turn yellowish, growing darker for two or three days, and perishing against the side of the cell, though not always the lower side. From four to six days are consumed in the drying-up process, and then if the comb is held a little slanting in the strong sunshine a dirty sediment will be seen at the lower side of the bottom of the cell, and will

sometimes hold together to be picked out in a chunk, with a dissecting instrument. The contagious type is more firm than the other; and if a quantity is put into a cultivating-glass, and soaked up, it will grow into a thick leathery mold at about 86°. The other seems to be a dust. The contagious type is the longest in its transformations, and in many cases the larvæ are capped, but the pupæ never develop. They never have with me, and I have one case of it now, if it has not been found by other parties and destroyed, though I think there is no possibility for that.

I think that thorough investigation will show as many as six describable diseases of the brood, and that the most virulent type will yet be more manageable than a sitting hen, and less to be dreaded than either the lead-colored or red-lice-like insects that I have tried for three years to bottle for Prof. Cook, but I can not succeed, though I find plenty of them. Who else has seen the "varmints"?

South Kent, Ct., Dec. 21, 1885. H. L. JEFFREY.

Friend J., if there are really six different kinds of diseases of the brood, I sincerely trust that the most of them are not very common. I do hope that foul brood may become as "manageable as a sitting hen," but I confess to a good deal of anxiety on the subject. I have recently learned from different sources that foul brood is raging badly in the vicinity of Toledo, O., and that large honey-producers are selling the honey from foul-broody colonies, to be scattered here and there. Now, then, friends, this is indeed a serious matter. If a single package of that honey should be thrown out in the yard, after the contents have been used for food, and bees from anywhere get access to it, foul brood will be introduced, and I do not know why we should not soon have it everywhere. From your description, I do not see why you should say the disease you have is not foul brood. Is it not near enough like it so it will come under most of the rules to be observed in ordinary foul brood?

ABSORBENTS IN WINTER.

SHIPPING-CRATES.

ON page 824, Mr. Robbins solicits some "reasons for the faith that is in me" regarding the above subject. On these pages he correctly quotes one of my statements regarding my opinion of the value of absorbents. Without consuming space in detailing the many examples that have forced me to regard moisture, of itself, not unfavorable to the health of our bees during winter confinement, I will say that numerous have been the cases coming under my observation, both in outdoor and cellar wintering, that force me to such conclusions.

The great factor for consideration, I believe to be temperature; and danger comes from the falling of the same. Humidity demands a higher temperature, which, if supplied, renders it harmless, its only ill effects being secondary, at the most. Prof. Cook's allusions to this question in his Bulletin No. 8, are statements that accord with my observations and experiments.

The best report of outdoor, or, I might almost say, of any kind of wintering during the past se-

vere winter, we receive from Drs. Southard and Ranny, of Kalamazoo, Mich. Their apiary of over 100 colonies was all outdoors, all packed with chaff, not extraordinarily thick, all with covers tightly glued on the hives, and suffered no loss. If Bro. Robbins could hear these clear, practical apiarists detail their continued experiments with absorbents vs. no absorbents, stating results, he would see just why they have discarded all of their costly cushions.

I trust that the readers of GLEANINGS have not forgotten that Mr. R. I. Barber and many others of our most successful "winterers" consider moisture either no detriment or a benefit. The reason why I said I believed upper absorbents were oftentimes "worse than useless," was because their adjustment is usually, or always, such as allows of greater radiation of heat than takes place where the packing is placed directly upon the tightly sealed board cover, and the consequent lowering of temperature is dangerous.

HUTCHINSON'S SIX-CENT SHIPPING-CRATE TO HOLD 14 SEVEN-TO-THE-FOOT SECTIONS.

I am pleased to note that Bro. Hutchinson can and will sell our shipping-crates at so low a price as 6 cents each. Here they cost more than that, and we are obliged to ask 10 cents each for them in any quantity. Even at that price we did not care to, and did not, supply them last season. In one sense you are quite correct in saying they are nothing particularly new. I have used them some five or six years, and will tell you how much I devised their construction. The first section-crate I ever saw came from New York and from Bro. Doolittle, if I mistake not. The glass ran the long (wrong) way of the crate. This glass was necessarily nearly as wide as the crate was high, and was held in place by sliding into grooves cut into the corners of the solid end-pieces. This crate held 12 two-pound sections. The two lights of glass cost more than Bro. H. charges for our little crate. This crate had to be handled wrong way to you, or have hand-holds cut in its solid ends. The latter course was chosen. The first change I made was to cut the notches for the glass in the side cleats, rather than the solid ends, and the need for only one-half as much glass was the result. I next applied the same principle to a two-story crate for 4½ sections, and this crate was illustrated in the *A. B. J.* early in 1878. In all these crates the combs ran the long way. When I began to confine the widths of my sections to a certain number to the foot, I saw that if I made a crate just a plump foot long, making the sides solid and the ends cleated for the glass, such a crate would embrace the following advantages:

1. It would hold just two of the four tiers held in our storing-case, and take them just as they came from the cases, if desired.
2. It would take three sizes of 1-lb. and two sizes of ½-lb. sections, fitting all perfectly.
3. While it shows the honey sufficiently to insure due respect from the carriers and satisfy the buyer, its construction is such as to cut the cost for glass down to a minimum.

4. With such a construction the end-cleats serve every purpose of hand-holds, and at the same time admit of carrying the crates in the most convenient position; also of carrying the combs in the safest position, which is to and from the carrier.

5. It shows off the honey to the best advantage.

6. As you say on page 756, a case thus constructed is light and durable, and better protects its contents from breakage.

7. Such small crates not only ship safer, but sell more readily. With them our commission men catch a great deal of retail trade, and our retail dealers often induce a customer to take a whole crate.

This is not all; but this article is getting long, and I desire to say that when these crates are made of white basswood, nicely dressed, they are handsome to look upon. Our experience teaches us that, especially with crates and sections, the best and nicest are cheapest. Trusting that your readers clearly understand the principles and advantages of the construction of the shipping-crate in question, it gives me pleasure to say to Bro. Hutchinson's inquiring friends, as well as to all, that I gladly grant to all the privilege of making any and all of my inventions or devices connected with this crate.

JAMES HEDDON.

Dowagiac, Mich., Dec. 7, 1885.

Very good, friend H., and I beg pardon for saying there was not any thing particularly new about this little case. Your seven reasons are all good ones; and while the case is nothing particularly new, it accomplishes a good many things that no other case accomplished in just that way before. You invented the case, and Bro. Hutchinson invented the six-cent price on it. We have had an engraving made, because our readers will catch hold of the special ideas so much better with the picture right before them. The question has been asked several times, if friend Hutchinson furnishes glass also with the six cents. We have replied that we thought he did not; but perhaps he had better so state it, in his advertisements or otherwise.

THE SOLAR WAX-EXTRACTOR.

THE HEAT OF THE SUN IN CALIFORNIA.

FRIEND J. P. Israel's description of his sun wax-extractor and its work (page 75 of GLEANINGS), is perfectly correct. If you will look at my article on "The California Sun-Strainer" (p. 339, current volume of GLEANINGS), you will see that it was formerly used exclusively for separating the honey from the wax, here. Even now it is indispensable to any California apiarist, as all the cappings (from extracting), all broken combs and scraps, and all comb honey, which from any cause has become unsalable, may be melted up, and the honey, wax, and refuse completely separated at one process. If a chunk of wax, or an empty new comb be left outdoors in the summer, in an iron pan, or in an inverted hive-cover, it will melt and soon become bleached to a snow-white. During the summer, the iron parts of a wagon or any other article or tool of iron will, in the middle of the day, become so hot from the rays of the sun that one can not take hold of it with the naked hand.

I have sometimes left a wooden paddle in the sun-strainer, and found it too warm for immediate handling. We have no need of steam wax-extractors here, except, perhaps, late in the fall, when the sun shines too obliquely to have full effect.

There has never, to my knowledge, been written an article on the sun-strainer, or sun wax-extractor, as you call it, which, as fully as the above-mentioned article of mine, describes the apparatus, its construction and use, and I think it will pay any one to read it over again, before attempting to improve on the original, or to invent something else for that purpose. No doubt, reflectors of bright tin, if properly attended to, would increase the effect; but if they are liable to be neglected, they had better be left off altogether, and the sun alone depended on to do its work through the glass.

WM. MUTH-RASMUSSEN.

Independence, Cal., Nov. 30, 1885.

Friend M., I beg pardon if I seemingly overlooked the great service you have done in describing the solar wax-extractor as you use it; but in reading your article we took into consideration the great amount of extra heat given off by the sun's rays in your State, as above, and therefore we did not feel certain that it was practicable here in our latitude. When friend Green informed us, however, that the heat of the sun is ample, right here in the North, as it were, it gave us an additional stirring-up; and while there is no need of reflectors or looking-glasses with you, it seems to me they would be quite a help here.

HUMBAGS AND SWINDLES PERTAINING TO BEE CULTURE.

MORE ABOUT " \$800 A YEAR " IN RAISING CARP.

IF our readers will turn to page 827 of our last issue, and read the communication from W. Baird, with our comments, then turn to page 829, and read "A Carp Swindle," by Milton P. Peirce, they will be prepared to connect the two after reading the following from the *Farm and Fireside* of December 1:

We caution our readers against a certain "U. S. Fish" company, nominally located at Columbus, O., and whose circulars are being distributed broadcast over the country, thanks to the gullibility of certain agricultural editors, who have given free advertising to this "Co.," through the medium of an innocent-appearing letter nominally written by one W. Baird, of Pittsburgh, Pa., in which is depicted the wonderful success a poor farmer has had in raising the mortgage from his farm by raising \$800 worth of carp on an eighth of an acre of land! It is simply a new dodge of the old J. M. Bain gang, of New Concord or Zanesville, Ohio. The gang, which under its various aliases of the "North American Poultry Association," the "U. S. Incubator Co.," etc., etc., has made a most unsavory reputation. The purpose of the present scheme is to induce gudgeons to send \$1 to the "U. S. Fish Co." for a "book" on fish culture. This "book," if it materializes at all, will be a pamphlet which might be worth 10 or 15 cents, if the matter it contains had any value, but which will in reality be worth just so much waste paper.

Will our agricultural papers please take notice? and if they have given publicity to this swindle, will they correct it by warning their readers accordingly?

VARIOUS MATTERS.

HOW THOSE BEES CAME THROUGH.

BEFORE me lies a card with this question on it: "Please tell us, through GLEANINGS, how the colony of bees you experimented with came through. See page 190, GLEANINGS for 1885." By turning to said page I find that the colony alluded to was the one in which I placed the thermometer the most times in getting the temperature of a cluster of bees in extreme cold weather. I there say, that I fear the experiment will cost me the colony, as they are getting quite uneasy, or words to that effect. Well, it turned out that this very same colony, which had stores of *honey and pollen*, being disturbed at least 12 times during the very cold weather of last February and March, proved to be one of my best colonies in May, and continued so throughout the year, giving me 112 lbs. of white comb honey and one new colony. Thus the advice, not to disturb bees in cold weather, did not apply to this colony; for in a few days after my experiments ended, I found them as quiet as any colony in the yard, and much more so than two-thirds of them were.

WHAT BECAME OF THE QUEEN?

The same questioner asks, "What became of the queen you placed under the Hill device over the colony? See page 231, of GLEANINGS for 1885." This alludes to the queen I took from a colony of bees just dying with bee-diarrhoea, which was put in a cage provisioned with Good candy, and placed in above, hoping to get her through to spring, as she was a very valuable queen. By the amount of food consumed, I judged she lived perhaps a month, but she had been dead some time when the weather admitted of my looking after her.

TEMPERATURE OF THE EARTH.

In the editor's talk on page 785 and 786 I see he places the temperature of the earth at 55°; and from what I read I judge that he gives that degree for the reason that he got the impression, either by actual knowledge or otherwise, that this was the temperature inside of the Mammoth Cave, in Kentucky. Now, while I know nothing of the temperature of the earth in Kentucky, I do know that 55° is not the temperature of the earth at 40 to 45 or less feet in depth, here in Central New York; nor do I believe it is in Ohio, where friend Root lives, so that his plan of using the heat of the earth for the growing of vegetables by means of sub-earth ventilation would not work here, I am confident. Five miles from here is a well 46 feet deep, at which I always stop and drink whenever I go that way in summer time. The means used for drawing the water is the "old oaken bucket," sang about in our childhood. Several times, both in winter and summer, a thermometer has been placed in the bucket and lowered into the water, which is from 38 to 40 feet below the surface of the earth. The temperature of this water has been found to be 41° in February and 43° in August, thus averaging 42° throughout the season, changing only two degrees between the severe cold of winter, and the extreme heat of summer. I also find that this is very near the temperature of my underground bee-cellar, when all is kept quiet and undisturbed; and if I recollect aright it is the temperature given of the earth in

Michigan, as given by Bro. Heddon a few years ago. I would naturally suppose that the earth in the Southern States, especially in Texas and Florida, would be warmer than where we have so much winter as we do here, which may account for the difference between Kentucky and New York. If I could have a bee-cellar which would give a steady temperature of 55°, without artificial heat, I should consider it a great acquisition.

Bordino, N. Y.

G. M. DOOLITTLE.

Friend D., I am rather glad to know that disturbing bees in mid-winter has not *always* been hazardous. May be, however, you handle them so carefully that you did not demoralize them as some less expert manipulator might do.—I am very glad indeed that you have brought up this matter of the temperature of the earth. I have had one other criticism on the same thing. One other friend says the mean temperature of the earth is 59 instead of 55°. Well, we have enough careful observers among our readers of GLEANINGS to settle this matter pretty conclusively. In regard to the well you mention, I should like to ask if you saw the temperature taken, and was the thermometer one that was reliable, or only one such as happened to be lying around? The well, you say, was 38 to 40 feet deep. In the Mammoth Cave we descended to a depth of several hundred feet. It is laid down in the physical geographies, that the temperature rises one degree for every 50 or 60 feet we go down into the earth. This, you know, might make all the difference.—No doubt you are right in saying that sub-earth ventilation would not give a temperature high enough for raising plants, and I thank you for the correction; but with a little aid from the heat of the sun, and occasional days when the outside temperature is above 42°, I think we could get along pretty well. Lettuce and radishes grow nicely at a temperature of only 45°.

FOUL BROOD.

ITS MANAGEMENT AND CURE.

FROM the *British Bee Journal* of Nov. 15 we extract the article below. I hope the editor of that journal will excuse me when I say that I think our friends across the water are to be congratulated on having so able a man at the head of their journal. Friend Cowan seems not only to be fully posted in every thing relative to the bee-literature of the present day, but he also seems to have at his fingers' ends all that has been said and written in years past, in regard to even the little details of bee culture. And this is most important for an editor. How else can he direct thought, and be able to judge of what is new and original, from that which has been gone over and over? The article was called forth from reviewing friend D. A. Jones's little pamphlet with the title of our heading. I trust it is indeed true, that the phenol method can be relied upon; but I confess that my faith has been somewhat weakened by the contradic-

tory reports from its use. I shall be very glad indeed to know that destroying colonies, by fire or otherwise, when afflicted by foul brood, is foolish and wasteful.

In this little pamphlet the author, who is well known as one of the largest and most advanced beekeepers in Canada, gives his experience of the treatment of foul brood by the starvation method. In his introductory remarks Mr. Jones says, that "much has been written and said on the matter." This is quite true, and perhaps more has been written and said on this very method of treating foul brood than on any other. As far back as 1767 we find J. G. Seydel, and in 1775 J. C. Voight, recommending a similar treatment. Then still later, in 1789, we find Bonner, and in 1790 Della-Rocca, both practicing it, and Quinby, in 1865, in his "Mysteries of Bee-keeping Explained," gives it as the only effectual cure. Since that time to the present, the same remedy, with very little variation, has been recommended over and over again. Although we have very little that is new to learn in the method, the pamphlet contains several interesting paragraphs which describe the appearance of brood dead from different causes. They are headed, Chilled Brood, Neglected Brood, Overheated Brood, Drowned Brood, Dead Larvæ or Brood, and lastly, Foul Brood. The descriptions are so clear that even a novice can distinguish between any forms of dead brood and true foul brood. Of chilled brood he says, "The appearance of this chilled brood, however, differs materially from that of foul brood: the larvæ are frequently found dead in all stages, from the egg to the perfectly formed bee just ready to gnaw out;" also, "that bees, almost fully developed, are found dead in the cells, retaining their shape and appearance, never sink back into that brown rosy matter which so plainly marks *foul brood*." Of drowned brood, he says that it occurs when colonies are placed on low ground, and when a sudden rise in the water overflows the bank of the stream, and the apiary is submerged. This brood differs from chilled brood, and, if not removed, becomes much more loathsome, and sometimes turns, he says, to foul brood, or to "what looks and acts so much like it that it must be at least a first cousin to it." He relates an instance of a man having 100 perfectly healthy colonies submerged during the months of August and September, and a large quantity of brood was drowned. The weather after this flood was warm and muggy, and all the colonies from which the dead brood was not removed became badly diseased. Salicylic acid and other remedies failed to cure, and Mr. Jones concludes that spores of the disease were in the honey, and states that "honey from the combs, when given to a healthy colony, produced the disease." He believes that "some diseases are started *de novo spontaneus*" (?), a belief that we do not share, as experiments by Tyndall and others have shown conclusively that there is no such thing as spontaneous generation, and that disease germs must exist before they can be propagated. In describing foul brood, the author says that it "is a disease *in the honey*, or, rather, that is where it appears to lurk." We confess, that, even under a powerful microscope, with a one-twelfth oil immersion objective, we have never been able to detect the spores of foul brood in honey, nor has Mr. Cheshire; and although honey has usually been supposed to be the medium through which *foul brood* has been propagated, we are not prepared to indorse the opinion that it is the only way. Mr. Jones says that "combs containing foul brood can not be used; at least, I have never been able to use them; no amount of doctoring that I could do would disinfect them." He says, freezing even at as low a temperature as 35° below zero did not kill the spores, and combs and honey after this freezing, when given to a hive, produced the disease, and warns bee-keepers never to attempt a cure by that method. Boiling the honey, however, for a few minutes, he says, failed to transmit the disease, and concluded by saying that, "after many trials, I proved beyond doubt that heat will kill the germs by which the disease is generated."

To understand the error of this reasoning, it is necessary to know something of the nature of the disease. In 1874, Dr. Cohn, than whom there is no greater authority, and whose classification of bacteria has generally been adopted, first pointed out that foul brood is caused by a *bacillus*, and subsequently Professor Schonfeld and others, as well as the recent experiments of Mr. Cheshire, have con-

clusively corroborated Dr. Cohn's statement. Now, we know that freezing destroys most bacteria, *except* the spores of bacilli, which, according to Dr. Klein, survive exposure to as low a temperature as -15° C., but that no spores survive a temperature of 120° C., so that we can quite believe that, at an ordinary Canadian winter temperature, the spores still survive. On the same authority we also know that most bacteria are killed if they are exposed for several hours to a temperature below 50° to 60° C. But here, again, the exceptions are the spores of bacilli, which require, according to Dr. Cohn, an exposure to the heat of boiling water for as much as half an hour before they are destroyed. Therefore ordinary boiling for a few minutes, as recommended by Mr. Jones, does not destroy the spores. We have no doubt that, in the hands of such an experienced bee-keeper as the author, this method has proved sufficiently satisfactory; and it is certainly an improvement on cremation, or total destruction of bees, hives, and combs, which Mr. Jones, having paid dearly for the experience, so severely condemns, having, if our memory does not deceive us, when foul brood first appeared in his apiary, sacrificed two or three hundred stocks in this way. But we would go a step further, and save not only the bees, but also combs and hives. Knowing as we do that the disease is caused by bacilli, we have simply to destroy these or prevent their development. Cold and heat will not do it; but salicylic acid, thymol, phenol, etc., prevent, even in great dilution, the growth of the micro-organisms; and practical experience has proved that, by using them, we can save whole colonies. We have known large apiaries, where foul brood was raging fearfully, cured entirely by means of salicylic-acid fumigation according to Hilbert's plan in one season, with much less trouble than any process of starvation could have done. Phenol, likewise, first recommended by Professor Butleroff in 1874, and subsequently by Gravenhorst, and latterly by Mr. Frank Cheshire, has also been proved to cure the disease. In the face of these facts we can not counsel our readers even to destroy their combs. In the last paragraph Mr. Jones recommends fasting, and describes his *modus operandi*.

His method is to shake the bees from the combs of the infected hive into an empty box, and to place a wire screen over the top, to close the entrance, and then carry them to some dark repository (a cellar if possible), turning the box on one side so as to have the screen at the side to allow the air to pass through. Darkness and a cool temperature are important, as also that the bees should be equally hungry. They are to remain in the dark repository until they show signs of hunger. This they will do in from four to six days, and they must be carefully watched three times a day after the third day, or they are liable to die very quickly. When sufficiently starved, which is known by some of them dropping down and crawling about in a slow, quiet manner, they are shaken in front of a hive prepared with some combs, and are allowed to run in just the same as a swarm. If there is no food in the combs the bees should be fed. The combs of infected hives should be melted into wax, and hives and frames boiled for a few minutes. The honey should also be extracted and boiled for a few seconds, and can then be given to the bees. The author further says he has never known the disease to be contracted by either queen or drones. Mr. Cheshire, however, has found both, as well as the workers, to contain bacilli; and Hilbert, in 1876, at the meeting of the German National Bee-keepers' Association held at Strasburg, in describing his method of treatment, stated that bees and queens exposed to the vapors of foul brood contracted the disease, and that the fungus (*i. e.*, bacillus) of foul brood could generate in the body of the bee. Even the ovaries of the queen have become infected. In twenty-five hives treated by Hilbert he found three such queens. We have ourselves found the juices of workers, when examined under a high power of the microscope, teeming with bacilli. We, however, recommend the pamphlet to our readers. It is written in a pleasant style by one of the most able bee-keepers in Canada; and they will find in it much to instruct, more especially the paragraphs describing the different appearances of brood dead from various causes. We thoroughly sympathize with his concluding remarks, that "Destroying colonies afflicted with foul brood by fire, or otherwise, we consider a wanton destruction of property."

In regard to foul brood lurking in the honey, I did not suppose its presence could be detected by the aid of the microscope; but it has been carried to healthy hives so many times by the bees robbing foul-broody colonies, it has generally been taken for granted that the contagion is carried with the honey. Feeding even liquid honey from foul-broody stocks has also repeatedly started foul brood, if I am not mistaken.

A DRONE-LAYING QUEEN.

A MICROSCOPICAL DISSECTION OF.—BEES STEALING EGGS.

ON the 15th of October, 1884, I packed in chaff or sawdust, on their summer stands, 16 strong colonies and 10 nuclei, of which I lost none during the winter. In the spring I sold four strong and two weak colonies, and lost one by robbing, while I was away from home. I was gone less than three hours; but during that time the colony was overpowered and destroyed. So I began the season of 1885 with 12 strong and 7 weak colonies. The latter I used for queen-rearing and for experiments. One of the experiments was to test the value of a drone-laying queen. In the fall of 1884 I received from Italy a very fine-looking queen, which the dealer said was a choice queen from his own apiary, and an excellent layer. She began laying in one week after her arrival here; but every egg, though laid in a worker-cell, hatched a drone. Thinking that she might have been injured in transit, and that possibly she would be all right in the spring, I gave her brood from other colonies, and wintered her. In February she began laying drone-eggs in worker-cells. During March and April I gave her colony several frames of worker-brood from other queens; then by placing empty drone-comb in the center of her colony I hoped to get some early drones. See did lay a few eggs in this comb; but with her queenly wisdom she insisted on going away from the center of the brood-chamber, and laying most of her eggs in worker-cells; but they all produced drones.

I kept her until in June, when I gave up the experiment, and destroyed her. On microscopical examination, the ovaries presented a normal appearance; but the spermatheca was empty and atrophied, appearing like a little knot or wart upon the oviduct. I have no doubt of the thorough honesty of the dealer from whom I obtained this queen. What caused her failure?

From the 12 colonies run for honey I obtained 600 lbs. of extracted and 500 lbs. of comb honey. Most of the extracted I have sold at 12½ cents per pound. Some I have retailed at 15 cents per lb. The comb honey I have sold mostly at 20 cents per lb., some at 25, the whole bringing \$185.00 here at home, or a little over \$15.00 per colony for those run for honey. From the 19 colonies, spring count, I now have 51 packed for winter.

I am testing the wintering qualities of the different races of bees by placing stocks from imported queens side by side, under as nearly identical conditions as possible.

Two experiments last season convinced me that bees can and will steal as well as sting—at least they can and will procure eggs for queen-rearing when no queen is in the hive. In looking through

colony No. 18 on the 25th day of last April I found they had neither queen nor brood. They were left as found, and on May 10th I examined them again, when I was surprised to find three queen-cells—one with a larva almost ready for capping (it was capped the next day), one with a larva not more than one day old, and one cell with an egg in, which hatched May 11th. There was not another egg nor larva in the hive save these three, neither was there any queen. Myself and two others looked carefully over the combs time and again. May 14th I gave the colony a frame of brood and eggs, and May 16th the cell that was capped on the 11th was found opened at the end in the regular way, while the two others were opened at the side. One had a dead queen-pupa in, while the other had been entirely emptied. I also found a fine virgin queen, evidently but a few hours old. May 26th she began laying.

LEVI C. JOHNSON.

Fountain City, Ind.

WHAT MUSICAL NOTE REPRESENTS THE HUM OF A BEE?

ALSO SOMETHING ABOUT THE FISH IN FLORIDA.

TELL Mrs. Chaddock that orange-trees bloom in February. If she wants to peddle oranges, she ought to be here now. The butcher brings them around every week in his meat-wagon, and sells them at a cent apiece, very fine ones too.

Ernest has begun to teach the juveniles to use their eyes. Tell them to use their ears too, and find out what note in the musical scale a bee hums on while gathering honey. If they know enough about music to run the vocal scale, do, re, mi, etc., they can easily determine.

When I was at the lake this morning, two bees came down for water, and one hummed on A, and the other on C.

How the juveniles would enjoy seeing the fish in our beautiful clear lake! They come rushing toward the bank, eager to be fed. One will dart off with a piece of bread in his mouth, and twenty others, perhaps, will chase him just like chickens, only their every motion is grace itself, and the sunshine glints on their sides and makes them shine like silver. They are of all sizes, from an inch long to eight inches. They leap half way out of the water, if real hungry, catching at the crumbs that float on top. They are bream and trout. The children are very careful not to frighten them, and I have seen the tiny ones eat out of baby's little hands, as she held the crumbs in her palm under the water. The larger ones are shy.

We had quite a large frost this morning, which turned the banana bushes black; but I notice the geraniums are all green yet. I have one in the front yard, ten feet around. The bees were carrying in pollen to-day, but I don't know where they got it. It was of a reddish yellow.

George asks, if he will write and tell you what note a bee hums on, will you send him Silver Keys? Stanton, Fla.

VISTA A. REDDING.

Thanks, my friend, for suggesting this matter in regard to the pitch of the note emitted by a bee's wings.—And so you do have frost in Florida, do you?—Tell George we will send him Silver Keys as soon as we get a new lot. We have disposed of a thousand, but I think we can easily use a thousand more.

WHAT TO DO, AND HOW TO BE HAPPY WHILE DOING IT.

Continued from Nov. 15.

CHAPTER IV.

Get wisdom, get understanding.—PROV. 4:5.

In these former chapters I have gone over many things in regard to heat, in order to give you a general idea of the many ways by which we may make use of the heat contained in the immense storehouse in the bowels of Mother Earth. Improvements are constantly being made in this matter of counteracting the frosts of winter, in some of the ways mentioned above, or by a combination of these different plans. Natural caves offer very great advantages indeed; and where they are near large towns or cities, I should say they could be very profitably utilized for furnishing constant supplies of air, warm enough for the purpose of growing many kinds of vegetables, or keeping domestic animals in comparative comfort.

There is still another plan, brought forward recently, of utilizing the heat from the warm or hot springs that are found in many parts of our country. The warm water of these springs can be conveyed in pipes under ground, so as to give us the advantages of a tropical climate, even in frosty regions. Where a warm or hot spring is found near to a large city or town, it ought to be very valuable for such purposes.

HEAT FROM THE CONSUMPTION OF COAL AND WOOD.

Most of us are so familiar with this kind of heat for warming greenhouses and buildings, that I need not dwell on the matter here. Besides, it will come up naturally as we get further along.

LIGHT.

We have already pretty thoroughly considered the subject of light, in connection with the heat from the sun's rays; in fact, the two are almost inseparable. In planning to secure the direct rays of the sun, however, for raising plants, we need a little more light than can be obtained from these direct rays. For instance, we want our plants close up to the glass, in order to get as much light as possible on all sides of them. If you were to permit the sun to shine into the back part of a cave, you would get enough heat, but not light sufficient. Even though the sun shone directly on to the plant, it would commence at once to stretch and reach forward, to "get out of the hole," as it were,

indicating its desire to get close up to the glass, or, if you choose, to get out where light would come to it from all sides. Our first greenhouse was built with a solid, opaque roof, on the north side. I did this, thinking that, as no sunlight could come directly through it, there was no need of going to the expense of glass. The result was, the plants under this north roof, although right in the sun, always leaned over to the south, and I was obliged to put them in movable boxes, which could be turned end for end every few days. On this account we want glass over the whole space above the plants, although the north wall may be opaque, and have double walls, with an air-space between them. To get all the light possible on all sides of our plants, we also paint every thing white. You will be surprised to see how much lighter a room becomes by whitewashing or painting all the objects or furniture white. Where plants are raised in the window, of course we have to turn them around to keep them from growing one-sided, and they do very well under this treatment, only it is somewhat laborious, where there are many boxes. Making a little room about the plants, and covering the walls with white paper, gives us more and better light. Sometimes hanging up white sheets around the plants will accomplish the same result.

As an illustration of what may be done with very cheap and common appliances, we take the following from the *American Agriculturist* for Jan., 1885. You will notice, also, that the friend who did it is occupied with office work, so that it was all done during odd spells that would probably have been spent in some sort of amusement that would have left no tangible result of any kind. It was to him a pleasure and a pastime, like building my monument.

STARTING A VEGETABLE GARDEN.

In the fall of 1883 I purchased some second-hand 4x6-foot common window-sash, at \$1.00 per sash, and built a lean-to structure on the south side of the barn, using four of the sash laid lengthwise for the roof, and two for the front side. The ends were sided up with matched inch stuff, allowing for a door at one end. Notches were cut through the cross-pieces of the top sash, to allow the water to escape. This gave a space inside of about 7 by 12 feet, allowing 2½ feet for the

two side benches, set three feet above the ground, and a pathway of two feet. On the side next to the barn were two benches consisting of two scantlings placed lengthwise, on which were shallow boxes filled with earth. This plan allowed of turning the boxes occasionally, so as to give each side an equal amount of light. About midway of the outside, or front, was a small self-feeding parlor stove, such as may be found among the second-hand stoves at almost any hardware store, and bought for five dollars. The stovepipe passed out through one of the apertures of the sash, fitted with tin, and extended upward eight feet, to give sufficient draft. A large amount of heat might have been saved by having the pipe run lengthwise of the building, though an even temperature of 60 to 70° was maintained during the daytime, and from 10 to 15° less each night. The fire was started Feb. 22, and never went out until May 5, consuming about three-fourths of a ton of coal. In this structure I started about 4000 tomato-plants, 2000 cabbage, and a quantity of pepper, celery, and lettuce plants. When sufficiently large, the plants were placed in hotbeds or cold frames outside. This enabled me to delay starting my hotbeds for such tender plants as tomatoes and peppers, until the latter part of April, and still have large stocky plants for outdoor planting by the middle of May. Early cabbage and cauliflower plants were transplanted into cold frames and made fine plants, "hardened off" sufficiently to set out April 20. My first sowing of tomato, cabbage, and cauliflower seed, was made Feb. 15. Subsequent ones were every four or five days. Plants of the later sowings were transplanted into cold frames, and protected at night with straw mats. The lettuce, besides being put into cold frames, was set out between early cabbages and cauliflowers in the open ground April 20, and made fine heads several weeks earlier than outdoor sowings. As I am engaged with office work during the day, the time devoted to the greenhouse was principally mornings before eight o'clock, a few minutes at noon, and at evening. The total expense of building the greenhouse and fixtures, heating, etc., was less than \$20.00, and my book shows a cash receipt, from plants sold, of over \$140.00. This includes receipts from late cabbage and turnip plants which were sown outdoors. The actual receipts from stuff started in the greenhouse show a profit of over one hundred dollars.

The time devoted to this work, besides being profitably spent, was more a pleasure than a task, as any one at all interested in horticultural matters generally takes enough pleasure in "watching things grow," to more than compensate for time and labor spent. I have gained many ideas from the past year's experience, which will doubtless greatly aid me toward greater success hereafter.

G. H. M.

WATER.

A good deal has been written in regard to watering plants; and my own experience has satisfied me that, to water successfully, we must imitate nature. Sprinkling the

plants constantly does not answer. In nature we have soaking rains, and then several days of sunshine; and I have never had any better results in watering plants than can be obtained by dipping the boxes or pots into a tub of water at about the proper temperature (say 55°, the temperature of the earth), hold them under the water until the soil is thoroughly soaked, then set them out to drain off. Of course, the pots or boxes should have ample arrangements made for drainage. Don't dip them again until the soil is found to be so dry that they really need water. Let them really *want* it, before you give them any more. Where plants are in beds in the greenhouse, flood the beds until the ground is soaked in the same way; then let them dry off. Circumstances must decide how often they are to be watered. If the sun shines every day, of course they will need watering a good deal oftener. The temperature of the room or the weather has also much to do with it. Sprinkling the foliage so as to wash off the dust, and keep the little breathing-pores in the leaves nice and clean, is, of course, a good thing. This imitates the dews of night. In watering plants outdoors we want to imitate the soaking rain; but, don't pour so much water right around the stems of the plants as to make a puddle, that will bake down hard. The usual way of watering, as they do in countries where irrigation is the rule, gives the best results. Make a little channel between two rows of plants; start the water in where the ground is highest, and let it run until it has soaked the ground clear up to the plants. Don't get on too much. Then turn it off, and wait until the plants really need water again. We usually prefer soft water to hard, though I can not see any particular difference, except that when the leaves and foliage are sprayed with hard water, it sometimes dries on them so as to leave a whitish precipitate. If a cistern is put in the center of your greenhouse, and all the water from the roof be conducted into it, it will usually give you all the water needed to water the plants. During severe cold weather, the water in this cistern may be warmed by a steam or hot-water pipe, and this will aid very materially in keeping an even temperature. The cistern may be under one of the benches; and if the water stands up within a foot of the soil above it, all the better. Such a cistern also aids in keeping a moist or slightly damp atmosphere.

SOIL FOR PLANTS.

What kind of soil is best for raising plants?

or, how shall we make or get the very best kind of soil? is a question that comes up constantly to young and old lovers of plants and flowers. So far as my experience goes, I believe I should place stable manure ahead of all other sources. Have it well rotted, so it can be raked up fine. If you can not get it well rotted, get what you can and rot it. Almost any experienced farmer or gardener can tell you what kind of stable manure is needed. Next, I believe I would have this stable manure composted, and mixed with decayed sods. Get sods from the roadside, or anywhere; pile them up in heaps until they are thoroughly rotted, and then mix them with your stable manure. In regard to the best kind of earth, I know of no better way than to get samples, in little boxes, of such soil as is procurable around you, and test it. I once got a wagon-load of earth down near the creek, that had been washed from a fertile hillside, or gradual slope. Some of them laughed at me for my pains, saying that my dirt was not good for any thing. But it grew plants better than any thing else we had. Woods dirt and decayed leaves are often collected with great care, and probably we shall find nothing better than decaying leaves. In view of this I think it is a very good speculation to rake up and pile in heaps all the leaves we can get hold of. Use them for bedding for the cow, horse, pigs, and even poultry. Cover the floor of the poultry-house with leaves to the depth of a foot, then scatter their feed in the leaves, and make the fowls dig it out. When the leaves get broken up fine they will absorb and hold the manure or the droppings from the fowls, so as to make them comparatively inoffensive; and the resulting compost is just the best kind of manure you can procure. If a peat-bog is near you, you can use vast quantities of peat in just the way I

have mentioned with leaves; but it should be thrown up in heaps or long ridges, to let the frost break it up fine and draw out the water. If your soil is of a kind that crusts over on the surface, and bakes, by stirring in the peat you can get rid of the baking, entirely.

Go all over your neighborhood; hunt up every thing that can be found, in the way of material that can be converted into manure. Get some experienced farmer (that is, if you are not an experienced farmer yourself) to tell you how much it would be safe to put in for old manure-piles; then when you have purchased them, scrape up carefully, with hoe and rake, the very ground on which the manure rested, and draw that away to put in your compost heap also. Get weeds, bog hay, and every thing you can lay hold on—refuse from the slaughter-houses, spent hops from the breweries (if you are so unfortunate as to have any such institutions near you), and waste material of every sort, in fact; and be sure you are not making a mistake. Make a test of all these things, as far as possible, before you buy any of them. Keep testing different materials and substances by growing seeds in little boxes, until you find what materials give the best results. Feel your way before you, as it were, so as to avoid making expensive blunders.

Now, before going further I wish here briefly to say something that touches on all the facts we have been over. In fact, it includes this matter of saving not only all the manures and fertilizers, but the summer showers and the winter snows, and all these gifts from God that are daily going to waste. It is, in short, a brief notice of a new book just published, entitled, "The New Agriculture; or, the Waters Led Captive," and we will take the latter part of the title for our next chapter.

CHAPTER V.

Can the rush grow up without mire? can the flag grow without water?—JOB 8: 11.

You will please bear in mind that the book was not received and read until after the foregoing was in type.

THE WATERS LED CAPTIVE.

This book, with the above title, has just come out within the last few weeks, and its author, Mr. A. N. Cole, of Wellsville, Alleghany Co., N. Y., is an enthusiast on the subject of growing plants. Although he is

a prominent character in political circles, he has, nevertheless, nearly all his life made the subject of plant-growing a hobby. When he was but a boy he got hold of the well-known experiment of growing a great crop of cucumbers in a single barrel. Perhaps many of our readers have tried it, and many more have heard of it. The way he did it was this: He procured a good-sized

barrel, sunk it half way in the ground, and filled it half full of round cobble-stones. On top of the cobble-stones was placed brush, then some straw, then a good deal of manure, mixed with nice rich earth. On this earth the cucumbers were planted in the ordinary way; and when the roots were long enough to go down among the cobble-stones, the barrel was kept constantly filled with water. Several conditions were necessary to insure the greatest success, so he made several trials of the process before he succeeded in getting nearly half a barrel of pickles from the plants that grew in a single half-barrel of compost. I presume the bung-hole of the barrel was left open, to guard against hurting the plants by too much water. In that case, if the earth should be soaked, no matter how wet, the surplus would flow out of the bung-hole, leaving the soil like any nicely underdrained soil, while the roots of the plants would always be able to help themselves to any amount of water required, by simply going down among the wet stones.

By the way, there seems to be something particularly attractive to the roots of plants in wet stones or damp gravel. Many of the friends who have practiced underdraining know how the roots will go down into these underdrains, and follow them for many feet. Friend Peirce, in his carp-book, speaks of the trouble he has had with outlets to carp-ponds, by the roots of the trees getting into the pipes, and filling them up. Well, there is nothing particularly strange about this experiment of raising great quantities of cucumbers with a little very rich compost and plenty of water. But here is the strange part of the experiment, and the one which fixed the attention of young Cole, and made this matter his life-study. That one hill of cucumbers in the barrel, during the hot days of July, when the plants were making their greatest growth, actually drank up *half a barrel of water, in only three days!*

Does it astonish you? Well, it astonished me somewhat; but when I gave our people at the noonday service an outline of friend Cole's wonderful invention, one of our men told me after dinner that he himself had done the same thing; but that, although he had not measured the quantity of water needed, he had no doubt that very rank, thrifty-growing vines, would take quite the amount mentioned. That is over 10 gallons of water a day, for a single hill of cucumbers. In other words, this one hill of plants drank up over three patent pailfuls of water

every 24 hours, or nearly half a gallon an hour; or, to get it right before us, a pint of water every 15 minutes. As it is likely that more water was used in the daytime than after nightfall, at some hours the amount perhaps exceeded even this. I have before called your attention to the fact that much of our garden stuff is largely composed of water. Green cucumbers may be 80 or 90 per cent water; and if the plant is going to yield bushels, of course it must have water to drink. Do you feel like saying, "Well, who wants so many cucumbers, any way?" I reply, strawberries, during the height of the fruit season, use almost as much water as cucumbers do; and friend Cole has been selling strawberries at a *penny apiece*, because they were as large as ordinary peaches; he did not raise them in barrels, though, and this brings us to the discovery.

A few pages back I talked to you about saving the rain and the snow, as well as the sunshine. Well, friend Cole has just "gone and done it." His garden is on a hillside, and he has made it to bud and blossom in such a way that the people of the surrounding country have got in the way of calling it "The Home on the Hillside." Our place is called "The Home of the Honey-bees," so you see there is something a little parallel in our experiences. For several years the idea has haunted me, that we ought to save the water that comes down from the clouds, store it up somewhere, and use it during our dry summers to give drink to our strawberries, cucumbers, etc. I talked about constructing a reservoir upon the hill near our house; but our land is so expensive here close to town that I could not well spare the room it would occupy. Besides, after I had got it made into a pond, it is expensive business running it over the land, even by the best system of irrigation. To see what had been done in the matter, I sent and got the little book, entitled "Irrigation Applied to Farms, Gardens, and Orchards;" but after studying the book for two or three years thoroughly, I became discouraged before I ever set about it. The author discouraged me by giving actual facts from experience, of the expense of irrigation after the water was obtained. You can not do it in one season so it will last, but it has got to be done continually. Friend Cole started out with the bold idea of *covering up* these reservoirs to hold the rain, and raising garden stuff *right over them*. I had thought of this too; but the expense required to cover a

small pond, so it would not break down and cave in, discouraged me again.

Shall I tell you how he does it? He just digs reservoirs across the side of the hill. These reservoirs are, in fact, nothing more than deep wide ditches. These deep wide ditches are then filled with round cobblestones, just on the plan of the cucumber-barrel. When he gets within 18 inches of the surface of the ground, he covers the cobblestones with thin flat stones, then he puts on brush, straw, etc., and then nicely prepared soil. Of course, this is to be done only where there is a clay subsoil that will hold water; but this condition can be found on almost every farm or garden. The depth, width, and distance apart of these reservoirs must depend on circumstances. But this new book recommends that they should be about 2 feet wide, $3\frac{1}{2}$ deep, and two rods apart, for farm purposes. For market gardens and small-fruit growers, they may be 5 feet wide and 5 feet deep, and not more than a rod apart. In that case the ground will all be thoroughly underdrained; and during the severest droughts he claims the growing crop will never suffer for water; for a reservoir, say $3\frac{1}{2}$ feet in depth, and three or four feet wide, placed under 18 inches of rich soil, if filled with water in the spring, would probably hold some part of it until along in the fall; that is, in retentive clay soil.

Each reservoir is to have its bottom on a level. For instance, you will commence on the highest point of land, if it is a hill or knoll, run your reservoir clear around, so it will be in the shape of a letter O with a spot of solid ground in the center, not to exceed two rods across. If the hill is oblong, of course your reservoir, instead of being in the form of a circle, will be oblong; that is, it is to conform to the lay of the land and the shape of the hillside. Now, one rod below this another similar structure is to be made. Now comes the question, How shall the overflow from the first reservoir pass into the next one below it? Friend Cole accomplishes this by means of some smaller ditches made in the same way, filled with smaller stone. These smaller stones are raked out of the soil when it is broken up fine, as it has to be for gardening and fruit-raising, and these smaller stones, or coarse gravel, act as a filter. The cross-ditches are a foot or two less in depth, and the surface of the small stones is covered with flat stones like the others, this flat-stone shingling being all of it at least 18 inches below the surface, so that no ordinary plow or subsoil

plow will tear it up. You will notice that the surface water filters from the first reservoir into the second; from the second into the third, and so on, until you come to the outlet. I hardly need tell an intelligent man that, if he puts the filthiest kind of water into the upper reservoir, by passing through so many gravel filters filled with roots of hungry plants, he would have nothing but the purest kind of spring water when it got to the outlet; and such, in fact, proves to be the case. The roots of plants are superior to any filter of charcoal, or any thing else, for removing all organic matter from the water that passes over it.

Those who visit friend Cole's garden on the hillside, and find strawberries as big as peaches, and plums as large as apples, a good many of them claim that his wonderful success is owing to the thorough way in which he digs the ground up, and makes it fine and mellow to the depth of 18 inches. This is in friend Terry's special line, as you may remember. Of course, while he is digging it up fine to get *out* the gravel, he also digs *in* a plenty of good manure, forest-leaves being one of his favorite products for fertilizing the soil. I presume he manures his five acres (for that is the extent of his little farm) very much as market gardeners usually make their ground; but he has obtained results away ahead of what market gardeners do.

Of course, friend Cole is an enthusiast in this new development, and very likely we should make some allowance for his enthusiasm; but for all that, I think he is destined to be called a public benefactor. As I have no means of testing personally his claims at the present writing, I can only state to you what seems to be sufficiently attested by many witnesses. Ground thus prepared and worked up is much less liable to the effects of frost than ordinary soil; for this large body of water so near the surface gives off its heat, and warms up the mellow soil above it. Secondly, his plants are rank and green much later in the fall than those on ordinary ground, and they also start out earlier in the spring. It seems to me likely that, if a natural spring could be turned into a reservoir, and allowed to pass down through, it would still further aid in keeping off frost. While heavy snows cover the ground, friend Cole says his strawberry-plants grow all winter, having their roots safely anchored among the wet stones in the reservoir. I suppose you are aware that steam has been used for years to furnish heat

for hotbeds, in place of fermenting manure. Well, with this arrangement, letting steam into the reservoirs, we furnish bottom heat for early plants very cheaply. If instead of water we say hot liquid manure, we have manure and bottom heat, just as they do with manure from hotbeds.

Perhaps I should add, before closing this subject, that friend Cole has a patent on the process; but after reading his book, I for one feel quite willing to pay him for the privilege of testing, say an eighth of an acre, on his system. Even if we do not use all his plans, I think we can, in this matter of growing plants and vegetables, made use of at least a great many of his suggestions. His invention seems to be providential, also, in a sanitary point of view; for these reservoirs take up and utilize all manner of filth, and standing water is out of the question. Only a few days before the book was received, I was feeling somewhat dissatisfied with our underdrains during this wet season, because it took them so long a time to get rid of the surface water. We wanted to bank up our celery, fix up our cabbages and turnips, and ridge up our ground so the frost could make it fine for us; but the ground was so wet and sticky everywhere, it seemed out of the question. After we have prepared our ground on friend Cole's plan, however, we can dig in it all winter if we want to. We expect to use the eighth-acre we are going to prepare, for raising early cabbage, celery, tomato-plants, etc.

Now, if some of you should write me and ask if I would recommend that you pay out money to go into this new kind of agriculture, I would say, unhesitatingly, *no*. If you can dig the trenches yourself, or if your men do it at times when they would do little or nothing else, by all means do it. Most of you probably have stones on your premises that you would be glad to get rid of, so you would certainly accomplish something in this direction. It certainly can not be any bad speculation to bury the stones that cumber your ground, where they will be out of sight and out of the way. For a garden-patch I would get a screen, or riddle, such as is used for screening coal, and screen or sift all of the ground in the garden, to a depth of 18 inches, or fix a small bed thus screened and pulverized, until you see how you like it. In working among plants, having the ground in beautiful order enables one to do more than double the amount of work; and all successful gardeners now advise manure without stint.

If we will only call to mind incidents familiar to most of us in regard to this matter, we shall see that it is not at all unreasonable. As an illustration, when we were planting our basswood orchard one end of the lot was disfigured by a cellar where a house had formerly stood. To fill the cellar up, we picked all the stones off the field and threw them in, big and little. Then we threw in all sorts of rubbish over the whole, plowing and scraping the dirt around the sides of the cellar until the ground was level. To get the ground in order, we planted corn. While planting the corn, I made the remark that it would "probably be of little use to plant any over that old cellar, for there is nothing but lumps of hard clay—not a bit of fine dirt." But just for the fun of it I let some corn rattle down through the hard yellow lumps. I didn't even stop to bring some mellow soil to put over the kernels. They just rattled down into the crevices between the clay, out of sight. The corn came up, and for a while looked yellow and spindling; but by and by the color began to change, and pretty soon it towered away above the rest of the field. The old cellar held water, and the corn-roots got down into the stone-pile and into the water; and even though the ground they stood in seemed to be the poorest kind of hard clay, the corn on that spot where the cellar was, was the finest corn I ever saw. The stalks were like trees, and every one contained two or more mammoth ears.

On our premises we have not the stone needed, without drawing them quite a distance, which, at this season of the year, would be more expensive than to purchase fragments of stone at the stone-quarry. We have just been offered such fragments for \$2.00 a carload; that is, a carload of 20 tons, the quarrymen offering them at this low figure in order to get them out of the way. They also offer a thin kind of slaty stone for covering that may be easily split to any thickness desired, for \$6.00. We shall use this material for fixing our eighth-acre, and the result of this experiment will be reported during the coming season, before this book of mine is complete.

With a suitable one-horse plow, and scraper to match, the excavating may be done almost entirely by horse power, or horse and man power combined. The nature of the soil has something to do in the matter. If the scraper is not at hand, or there is not much to do, loosen the dirt with a plow and throw it out with shovels by hand.

CHAPTER VI.

In the sweat of thy face shalt thou eat bread.—GEN. 3:19.

This book, you know, is to tell you what to do when you are out of work, and also how to be happy in doing it. Now, I think a good many people spoil their chance of happiness by being too ready to give up to bad weather, a slight indisposition, and other like difficulties in the way of making every day count a good day's work. Last night we made all plans for excavating dirt at a rapid rate by the use of a team early this morning. In fact, I asked the hands to be ready, if they could, as soon as it should be light enough to see. We were making an outdoor cellar for fruits and vegetables. Remember, it is now the 5th day of December. Well, in the night I was awakened by the fierce howling of the wind, and was not surprised when I went out before daylight to find the ground partly covered with snow, and a fierce storm of wind and snow from the north-west. Everybody shivered, and told how dreadful the weather was. I ran over my help mentally, and decided which ones would be likely to be willing to go out in the storm. I did not expect any of them before daylight. But I did go out and work half an hour myself with pick and shovel, to see how much the ground was frozen, and to see, also, how disagreeable it might be to work out such a day. I want to explain further, that I have been lately feeling a touch of my old malady; and when it was time to get up in the morning, my joints felt stiff and sore, my throat warned me of the approach of the hard cold that for a year back has been some way hanging about me much of the time, and I had a sort of feeling that may be has oftentimes tempted other people, even before they are fifty, to think, "Well, I am fast getting to be an old man, and it would be nothing strange if my best powers, both of mind and body, were passed by. Probably ten years more and I shall be all gone to pieces, or laid in my grave." Did you ever have such a feeling? What did I do? Get up late, and drag around after I got up, with a kind of long-faced, mournful air and gait? No, sir; I did nothing of the sort. I went and shoveled dirt until I felt perfectly well, had a big appetite, and it was breakfast time. When I got over to breakfast, the baby had the earache, and the oth-

ers were so long in getting up, on account of the cold, I was informed that breakfast would not be ready for fifteen minutes. I went back, and found one or two of the most enterprising of the men, and made arrangements to have the team and plow and scraper start at once. I was told we had no scraper suitable for the work to be done, and borrowing one was suggested. I do hate the very thought of borrowing tools—especially such tools. Our neighbor across the way had just such a scraper as we wanted, but he loaned it to Mr. A., and Mr. A. loaned it to Mr. B., and Mr. B. said Mr. A. took it home; but Mr. A. said Mr. B. took it home, while my neighbor across the way said it had not been brought home at all, although it was loaned months ago.

"No, boys, don't borrow any scraper at all. We will take that old one that we used to fill underdrains with, and try to make it work for to-day."

They felt pretty sure it would all come to pieces; but I told them we would plow the ground up very mellow, and take small loads, and thus avoid not only breaking the scraper, but fretting the horses. It is now half-past nine, and the scraper, in the hands of careful men, is doing splendidly, even though the thermometer is only 19 above zero, with the wind blowing almost a gale. The dirt moves beautifully, and the hands, after being once warmed up to their work, don't find it disagreeable. When I went to put on my stockings in the morning, I found one of them wet, on account of a hole in my boot, and that accounted for the bad feeling in my throat, and rheumatic twinges in my joints. I put on some dry stockings, a pair of overshoes, an old overcoat, and a pair of woolen mittens that my good mother knit for me last winter, and I enjoyed working in the dirt so much that I feel like laughing at my feelings of the morning. I have not only all my natural energy, but I feel stronger this morning than I did when I was twenty-five or thirty years old; that is, I feel more like shoveling dirt and holding a scraper now than I did then. More than all the rest, my heart is full of thanks toward God that I am permitted to work outdoors when I know my health is suffering from too little

just such exercise in the open air. I am not only full of love toward God, but of love and charity toward my fellow-men.

Do you want to know the moral of this chapter? It is this: If you want to be happy in doing the work that lies before you, get up bright and early, even if it is stormy. Clothe yourself warmly and *wisely*; then go out into the storm, and do whatever has to be done until your whole physical body glows with the effects of exercise in the cold wintry air. Then shall you find despondent and dismal feelings gone; and if your experience is like mine, you will find your aches and pains are gone too. Work in the dirt, even if the dirt is freezing. It is cheaper than doctors' prescriptions, and more wholesome and profitable every way. If the work to be done is something that your heart is in, you will soon be full of enthusiasm, for you will be in your natural and normal state. Now, then, don't say you can't get ready for the gardening operations of next year because the weather is too bad. If you have already something on hand more profitable than the work I have suggested, then you do not particularly need this chapter.

It is now four o'clock. As the storm continued unabated, when the noon hour approached it seemed even more important that our excavating for the time be finished to-day. I knew it was rather unpleasant to work out of doors; and so at the noon service I mentioned the reason why I was anxious to have the work done, and suggested that if any of the men employed in other departments of the factory would like to take a couple of hours digging the dirt, I should be quite glad of their services. Before half-past twelve, one came forward saying that he would work in the dirt if I wanted him to, and then another and another, until we had all the help wanted; and by the time I got back from the Saturday afternoon prayer-meeting, the work was safe from the weather, and a roof of boards placed over it.

Just at this time it was suggested that some apples in an out-building were in danger of being frozen. By the way, before I get through with these talks, I expect to have a chapter on apples. Well, one of the men handed me an apple, telling me it was frosted on the surface a little already. It

was a Peck's Pleasant; and if I had been governed by my feelings at the time I tasted of that apple, and I had been appointed to decide which was the best apple in the world, I should have unhesitatingly said, "Peck's Pleasant, by all means." Why, the flavor of that apple was most exquisite. I do not know that I ever tasted of any thing in my life — apple or any thing else — so *wonderfully* refreshing and delicious. Do you know why? Bless your heart, I had been working in the dirt, in the frosty air, until I was full of animal spirits, and just a little thirsty — just where I could appreciate to the fullest extent a nice apple. It was just frosty enough to make the juice cool and refreshing. Ice-cream and ice-cold lemonade are nowhere. Do you see the point? One who sits in the office all day, reading agricultural papers and letters from the farmers, can no more enjoy to the full a good apple than any thing in the world. Perhaps everybody is not like myself; but God made me to stay outdoors — at least a great part of my time. There is a short verse in the first chapter of Isaiah that reads this way: "If ye be willing and obedient, ye shall eat the good of the land."

At another time, when I had been at work out in the frosty air, one of the men was pouring some California honey into a can. It was so cold that it did not run well; but it was beautifully transparent for all that, and I thought I would just sample it. The honey was like the apple. It seemed to me that everybody ought to go into ecstasies over the exquisitely beautiful flavor of this mountain-sage honey. Why, if it would not have been undignified, and out of place, I should have thought it the proper thing to swing my hat and thank God for such a beautiful gift to man. I think this kind of honey was some that my friend R. Wilkin, of San Buenaventura, Cal., sent me; but as it had been standing in that can a year or more, I had never thought before about its being particularly nice. It was not the apple, nor was it the honey. It was just *myself*, because I had been out of doors, pushing ahead with mind and muscle in exploring God's gifts. My friend, do you think it a hardship because God has said, "In the sweat of thy face shalt thou eat bread"? I do not. I thank him for the privilege.

To be continued Jan. 15, 1885.

He that is faithful in that which is least, is faithful also in much.—LUKE 16. 10.

MYSELF AND MY NEIGHBORS.

EXCELLENCE OR CHEAPNESS—WHICH?

Through wisdom is a house builded.—PROV. 24: 23.

WELL, little friends, the convention of bee-keepers of North America have appointed your humble servant to give them a talk about excellence or cheapness; and as the talk I propose is to be a sort of neighborly chat, I thought I would just put it in here for you to read.

I do not know but that this subject was given me because some of the brethren think I have been a little too eager to recommend cheap tools and appliances; and may be they thought I would defend my side of the subject while somebody else would take up excellence rather than cheapness. Now, it seems to me that wisdom and experience should guide us in this matter, and that we can not very well lay down *general* rules for purchasing bee-supplies, or for *purchasing* any thing else, in fact. Isaiah tells us, in his first chapter, to "learn to do well;" that is, doing well is progressive; and I should also say, learn to purchase wisely. If you have got a little money that you want to invest in bee-supplies, don't be in a hurry to get rid of it all. Our text says, "Through wisdom is a house builded;" and I should say, through wisdom we make prudent purchases.

Suppose a boy gets big enough to need a knife. What kind of a knife should he purchase—a five-cent knife or a two-dollar knife? Why, I should say it depends upon who the boy is, his age, and what he wants

to do with the knife. But with the average boy, I think it would be a pretty good idea to try the cheap knife first. Even if he has laid up a couple of dollars to buy a pocket-knife, I think he will get more satisfaction by trying a cheap one first than by trying the two-dollar one first. If the cheap one does not please him, nor answer his requirements, it would not be very much expense to give it to some other boy, and try a little better one. Let him carefully *examine* and test each knife he buys, until he becomes a tolerably good judge of knives, and is able to purchase understandingly.

There are a great many people, and good people too, who have a way of saying, in regard to every purchase that comes up, "The best is the cheapest." A good deal depends upon what you mean by *best*. Suppose you want a hammer. There are hammers in the market, for only five cents. They are not loose nor rickety either, for they are made all of one piece of iron; and although they may be awkward and cheap-looking, they will do a vast amount of service for many kinds of work. They cost so little that if somebody borrows one, or loses it, it does not matter much; and I have found it quite convenient to have these cheap hammers scattered all around the premises. We have one down in the barn, and one in the stable out in the lots. The children have them to crack nuts; and, in fact, there are so many of them on the premises that whenever you want some sort of hammer for just a minute, you can almost always get hold of one of these, without going a great way or hunt-

ing very long. But, do you think I would give a good mechanic such a hammer to put up hives with? By no means. In putting up hives he uses a hammer almost constantly; and if I could find a hammer *worth* five dollars, I would give it to him without hesitation; for if it were worth only *a cent a day* to him more than a cheap hammer, it would soon pay for itself. For this same reason a good mechanic ought to have at least three hammers, and *three good ones*. Now, when I say I would give a hammer worth five dollars if I could find it, I do not mean that I would buy one that is silver-plated, or has inlaid work in the handle, and things of that sort; neither would I give him a hammer that had a great amount of unimportant work put on it. One of our large railroad companies paid \$60.00 (I think it was), for a dozen hammers to be used by some of their expensive men. These hammers were all worked out by hand, and were very handsomely made. I do not believe it will pay many bee-keepers to use tools or appliances made in this way. When he gets to be so well off in raising honey and bees that he has some money he really does not know what to do with (I wonder if there are any such here to-day, friends), it may be just the thing for him to do, to buy a six-dollar hammer to make hives with, because, you know, "the best is always the cheapest."

Suppose somebody of limited means wants to try bee-keeping. What kind of a colony of bees should he buy? Without knowing anything about the general habits of the man or woman, I would say, let them get the cheapest colony of bees that could be found in the neighborhood, thus saving expensive transportation charges, and also making their purchases of friends and neighbors. Then I would advise getting an Italian queen; but as I have said before, if one is new at the business, and may be, likely to make blunders at first, I would tell him to get an untested queen. After he introduces her all right, and gets her to laying, if she does not turn out well in every way, let him try a higher-priced one next time, working progressively; and my experience convinces me that the best way in the world to get any thing of this kind is to get it *progressively*. *Learn* to do well, not undertake to come up to the highest standard all of a sudden. There is far more enjoyment in making a little more improvement every day, than in stepping into great things, even if it could be done. The same with hives. I would first get a cheap hive—say a Simplicity. When winter comes, get a hive suitable for winter, even if it does cost a little more; but save your old Simplicity for your increase when spring comes again.

If you are going to make hives, start out with few tools, and purchase judiciously each new season, as you find you really need to. Do not get any thing to be put away on the shelves until you may need it. Purchase what you need, and no more, until you have pretty surely demonstrated it would be prudence to purchase larger lots for the sake of getting better prices. If you have worked with comb foundation enough to know that you want to use it largely, you can, from

past experience, usually figure out how many colonies you will need to have, to think of buying a foundation-machine.

There is another point to be considered right here. Sometimes cheap tools and cheap machinery make us so much bother and worry that they spoil all the pleasure of trying to keep bees; whereas a high-priced tool or a high-priced machine would go right along, without any hitch or accident, in such a way that the work would be only pastime or "fun," as the boys say. Where one's time is valuable, or where he already has many cares and responsibilities, nice tools or nice machinery all in perfect working order is by all means the most satisfactory, and, I believe, the most profitable. This latter point comes in more with tools or machinery that is necessarily somewhat complicated. We had some experience in this line in making and sending out rubber plates for making foundation. While *we* made the machines work nicely here in the factory, and while a few of our customers were pleased with them, the majority found there were so many conditions to be observed, and the whole arrangement was so uncertain in its results, that I have always regretted that I advised any thing of the sort. The same remarks will apply with force to home-made honey-extractors. We have for years sold the inside work, so that the friends who wanted to economize could save something by attaching it to an ordinary tin can or barrel; but as a rule, I believe they found it more vexation of spirit, and perhaps more expense in the end, than to have purchased an extractor all ready for use. Where one has a great many bees, and a good market for extracted honey, perhaps friend Stanley's automatic extractor will be found to be cheaper than any other.

In regard to bee-feeders, my experience has been in favor of something very plain and simple. One of our bee-friends once made a remark in jest in one of the journals, that every bee-feeder and bee-hive, according to *his* notion, ought to have "cog-wheels," slides, and levers, somewhere about them. Now, "cog-wheels" work very nicely in a warm room on a winter's day; but when you get out in the apiary, among the bees, about harvest time, when every thing is crowding, the said *cog-wheels* seem to be somehow out of place. Let us have our implements plain, simple, and substantial; let us pay enough for them to have every thing exactly as it should be—hives and frames interchangeable—every thing so it will work easily and surely; no sticking nor jamming nor pounding to get things in place.

In regard to utensils for honey, I believe the demand seems to be in favor of cheapness—tin pails that are to be given away, as well as crates to hold our comb honey. Sell the honey for so much, *package and all*. But even though we give them away, let us have them well enough made to be sure there will be no leaking nor daubing.

In regard to honey-knives, I would advise, as I advised the boy with his first pocket-knife. If you have few bees, and don't expect to go into the business largely, you can

make a 10-cent garden-trowel do your uncapping very well for quite a while. When you need a better uncapping-knife, get it.

In regard to perforated zinc, and things of this sort, don't include any in your first purchase. Wait until you feel the need of such new implements. May be you will never need them at all.

Even though I advise economy in purchases, I would have every thing that stands out in the weather painted. If you say you can not afford it, I would have half the number of hives, and have them protected from the weather by paint, rather than increase so fast, and have the weather constantly spoiling my implements. Besides, I would pay *something* for the sake of having things look decent and in order. A great many times, nice-looking implements encourage us to renewed energy; and sometimes just a little extra energy makes all the difference between success and failure, or profit and loss.

Every man who has honey to sell ought to have some sort of scales to weigh it on. The family steelyards will do to start with; but whenever you begin to take time enough in the course of a year, in using steelyards, to pay for a pair of scales, get the scales, but don't get them sooner, if you are cramped for means. When your business increases so that it will pay to have still better scales, get them. Don't waste the price of a good article in bothering with a poor cheap one.

In regard to seeds for honey-plants, go slow, unless, indeed, you are a farmer, and can raise alike, buckwheat, rape, or raspberries, so as to make it a paying investment aside from the honey. If you can do that, by all means raise honey-plants. I am led to make these remarks, because some of the new friends seem to think the first thing to be done in starting in bee culture is to get a pound of figwort seed, and four or five pounds of the spider plant, just because these plants yield honey in such quantities as to be visible to the naked eye. Buy a five-cent package of these seeds first; and if they please you, plant more the next year, by which time you should have seed of your own raising.

In regard to sections for comb honey, as the appearance of this product has a great deal to do with the price obtained, I think it very likely that the *best* is the *cheapest* every time.

When you find you need a smoker (and you may need it the first day you can call yourself the owner of a small colony of bees). I should say, try a cheap one to start with. But perhaps you can decide what you want before you buy by examining them at conventions, or testing those used by your neighbors. I say this, taking it for granted that bee-keepers are always *neighborly*. Is it not so, friends?

In looking to living-boxes, I have sometimes thought I would about as soon have a half-bushel or peck basket fixed to a pole, as to have any of those in the market. Maybe, after having tried them, though, you will think differently.

When your business arrives to the dignity of requiring a steam-engine, it will pay you to look into the matter very carefully. If

you can, go and see the engines made near you. But as I said before, be sure you need one before you get it. If you are doing your own work, decide how cheaply you can afford to furnish power by treading a foot-power machine. Whenever an engine would save you \$25.00 a year for power, if you can raise the money to buy it, without cramping yourself, buy one of one or two horse power. When you need a larger one, you can, as a general thing, dispose of the smaller one, or turn it toward another one as part payment.

While some folks get along nicely without any veil at all, others save time and save their nerves, by using veils. The same may be said in regard to gloves, although for myself I should certainly never use the latter among bees; and if I had the *entire* management of an apiary, I do not think I should ever need a veil. Cheap home-made veils will answer a very good purpose; but there are no gloves that will do, except the regular rubber gloves made for the purpose.

Prudence and economy would dictate some sort of wax-extractor. But don't buy one until you have discovered you need one. If you commence on a small scale, as you by all means should do, I would get a cheap one first.

TAKING CARE OF THE TOOLS YOU DO GET.

Now I am going to talk a little on the above, even if the subject has not been assigned me. A cheap, low-priced tool may be so well *cared for* that it will always give excellent results; whereas, the most expensive tool may be so *badly used* that it will very soon give *poor results*. Have for your tools regularly assigned places. Where any tool is wanted in different places, I would have duplicates. For instance, cheap brushes for brushing off bees should be in handy places in the honey-house, and in several places about the apiary, at least during the summer time. The same may be said of hammers. Do not leave any kind of tool out in the rain. Keep every kind of tool not only well oiled on the moving parts, but oil it to prevent rust. Oil the hinges to the door of your honey-house. Rub tallow on the windows so they will slide easily up and down. Keep your lawn-mower nicely oiled, and out of the rain. Have your brooms hung up in broom-holders so the ends will not get rolled up and made useless; and keep the brooms out of the rain also. If you use a wrench, keep it nicely oiled and in place. And this matter of oil is of so much importance that I would have cheap oil-cans filled with oil, on nice little bracket shelves in the barn and in the stables. A little box should also be there, filled with tallow, where it can be had in a moment. A great many times the oil-can or the tallow will enable you to use a hand-saw so as to do the work in half the time it would if you had not used it. With steam-engines, and machinery for hive-making, oil is a necessity; and those who neglect to have it handy will sooner or later have to pay heavy bills for repairs that a few drops of oil might have saved. Nails and screws of different sizes should also be kept where you can put your hand on them quickly. Whether you are a bee-keeper or not, you need screw-

drivers and adjustable wrenches, where any of the children can get them in an instant, if you tell them the tools are wanted in a hurry. And, my friend, as you value the future happiness and comfort of those children, teach them to be sure these things are put back in their places as soon as you are done using them, if you should forget it yourself. A girl five years old can easily save the time of a man and a team, may be, by knowing where to find a wrench or an oil-can; and the little girl will get it, and put it back, quicker than a big man could. That is one reason why I like little girls, and little boys too, because they can help such a "big lot," when they get into the way of helping, and when their papas make friends with them. I wonder how many of the papas to whom I am talking to-day are in the habit of making friends with the little chicks at home. Why, if you don't you lose half the pleasure of success in business. When a big crop of honey comes, and the prospect is before you of being able to pay off debts that have worried you, what a rare pleasure it is to be able to tell the children about it when you tell mamma, and have them rejoice and clap their hands too!

There, friends, I thought I was going to make a very short talk this time; but somehow, when I got a going it "talked itself." Good-by.

MRS. HARRISON TALKS TO THE JUVENILES ABOUT PETS.

WHAT SHALL BE THE CHARACTER OF THEIR LETTERS?

MY DEAR JUVENILES:—I take a great deal of comfort reading your little letters, where one says she has a kitty, and another a bossy. Some older persons may think your letters of little account, but I do not. I feel quite frisky, although I have lived in Illinois half a century, and in Ohio awhile—I shall not tell you how long, though.

I am not too old to go to Sunday-school. I was there last Sunday, and two strangers were there, and wanted us to form a "Humane Society;" that is, a society whose members promise to be kind to everybody, and to the horse, cow, dog, or cat; oh, yes! to the elephant, lion, tiger, mud-turtle, and every thing that lives—even to little boys who throw stones at our windows, and steal our grapes.

My dear children, your pets do you a great deal more good than you are aware of. Some persons who belong to the Humane Society visited the penitentiary—not one, but a whole lot of them, and asked the prisoners who of them had pets when they were little children at home. Would you have believed it? not one ever had any—not even a cat to purr around and rub against his legs, or a pet toad to live under the doorstep. Don't you pity these poor fellows who had nothing of their own to love, and so their hearts grew hard and wicked? I am almost afraid to join the Humane Society, for at their meetings they ask the members who have hurt any thing since the last meeting, to raise their hand. I am afraid I should have to stand up and say, "A bee stung me, and I hit it and killed it." And when the president asks me what made the bee sting me, I should have to tell

"the truth, the whole truth, and nothing but the truth," and it would be this: I went to their hive, jerked off the roof, jarred and banged around, scaring the poor bees out of their wits, who thought their home was about to be torn down over their heads, their babies killed, and their honey all eaten up.

Are the bees to blame, when they try to drive me off, and shoot at me with their tiny guns? Our country's laws protect us in our own homes, giving us leave to shoot or drive off persons breaking open the doors to steal from us; and should not the bees have some rights too? If a person knocks gently at our door, we open it, politely speak, ask him to come in and "take a chair." If I treat my bees as politely, do you think they would sting me? or if I ask their permission, by gently tapping at their door, and am not boisterous or rude, and have no irritating odors about my clothing, from bee-poison? I have tried to be kind to my bees in a general way. I have fed and watered them, and made warm bed-clothes for them; but I am going to try to be kinder still—treat them more politely, wouldn't you?

My bees go to a public well near by, and sip the fresh water from the gravel; they are attending strictly to their own business, and do not sting; yet boys who gather there kill all they can. Where there are new houses building, and they have beds of mortar, bees sip from it, and boys with little paddies spat every one they can, down into the mortar. Is this being humane?

Peoria, Ill.

MRS. L. HARRISON.

Well, now, really, Mrs. Harrison, I did not intend that our little friends should not tell about their pets, and confine themselves to bees, instead. My purpose was to avoid a little sameness in their letters, and at the same time give them something useful to do. Perhaps I put it a little too strongly, and gave a wrong impression. If I did, I heartily beg their pardon, and thank you for your seemingly indirect, but kind criticism. You notice that the juveniles still mention their pets in their letters as before, but yet I think they should not be inserted unless of some interest. We have more letters than we have room for, and we think that only the best should go into print. It seems hard, I know, to show partiality to our little friends.

A society like that you mention has only recently been formed here in Medina for the suppression of cruelty to children and animals. Father and myself are members. Each member is expected to report promptly any act of negligence or cruelty, to the marshal.

I agree exactly with what you say about pets for children. There is something so innocent about these little dumb creatures about us that God surely intended by them to teach his little folks lessons of love and purity. The younger members of our family take great comfort with those baby-rabbits that Caddie told you of. When I was quite small I used to spend hours with my rabbits and doves; and when perchance one of my pets was killed, I would sit down and have a big cry over it. I don't think it hurt me either. By all means, let the boys and girls have their pets. Such harmless amusements will tend to keep them from associating with bad company, and make them love all God's creatures. ERNEST.

Every boy or girl, under 15 years of age, who writes a letter for this department, CONTAINING SOME VALUABLE FACT, NOT GENERALLY KNOWN, ON BEES OR OTHER MATTERS, will receive one of David Cook's excellent five-cent Sunday-school books. Many of these books contain the same matter that you find in Sunday-school books costing from \$1.00 to \$1.50. If you have had one or more books, give us the names that we may not send the same twice. We have now in stock six different books, as follows; viz.: *Sheep Off, The Giant-Killer, The Roby Family, Rescued from Egypt, and Ten Nights in a Bar-Room.* We have also *Our Homes, Part I, and Our Homes, Part II.* Besides the above books, you may have a photograph of our old house apiary, taken a great many years ago. In it is a picture of myself, Blue Eyes, and Caddy, and a glimpse of Ernest. We have also some pretty little colored pictures of birds, fruits, flowers, etc., suitable for framing. You can have your choice of any one of the above pictures or books for every letter that gives us some valuable piece of information.

"A chiel's amang ye takin' notes;
An' faith, he'll prent it."

YOU are taking hold nicely in the problem which I gave a short time ago. So far we feel tolerably certain that a bee dies after having stung, and that, too, a few hours afterward; but let us have more reports until we are absolutely certain. While these things are important, little folks, there is something else that I wish to call your attention to.

Did you ever see a bee that acted as though he were real mad, and while buzzing before your face fairly boil with rage until you think that he has almost a human temper? I wonder if a bee ever tries real hard to control himself. I presume not; for how could he know any better? We have an old horse, Jack, by name, that will lop his ears flat upon his head, and his eyes seem to be ablaze with evil spite. There is one particular thing that he doesn't like to do; and this is, to back. He can't see the need of it, and will, if he can, smash something by one big lunge backward. I wonder if he tries to control himself.

Little boys and girls act very much like those dumb creatures. They have their good days and bad days; they have things they don't like to do; they have their spells of being cross at every thing. Sometimes, when Huber is a little naughty, we ask him if he is a good boy. "No, bad boy," he will say, while his face, with a dignified expression, shows that he meant what he said. I wonder how many little boys have just a little of the fire that a bee has. The little bee probably does not *know* that he is doing wrong; but God loves his little children vastly more than he does the bee or the horse, and he has made the little boys and girls to *know* when they are good or bad.

Now, little friends, see if you can't please God and help your mother by trying real hard. Some time you will find it not so easy

when you get old, if you don't begin now. When you are asked to do something that is disagreeable, not only do it, but see what a pleasant face you can have while doing it. If the bee or the horse doesn't know it is right to control himself, you do. ERNEST.

150 SWARMS KILLED BY BLACK HONEY; MEXICAN PONIES.

My papa takes cousin Caddie and me down to the River farm, where he keeps bees, when it is warm and pleasant, and gives us lots of honey. This year it was real nice; but last year it was black, and we did not like it. Papa said the bees gathered it from the leaves of the trees, and it killed 150 swarms for him last winter. On the same farm we have a pony, and it has a little flesh-colored colt with pink eyes. Papa thinks it's a daisy, and perhaps I am going to ride it some day. MABEL HARRINGTON, age 7.

Medina, O., Dec. 1, 1885.

I will explain that Mabel is Neighbor H.'s daughter, and she is also a playmate and cousin of Caddie. They are nearly of a size and age. As I was going up the street yesterday I saw them a little ahead of me, and I declare I could not tell "which from t'other."—Yes, that colt of cream color and pink eyes is a real beauty, and is what bee-keepers would call an albino. His mother is a mustang, and was caught right off the plains. Neighbor H. used to let me ride her around horseback.

I remember once that she took fright at something, and made a bee-line through the apiary whilst I, clinging to her back, began to see visions of broken hives, stinging bees, and myself bleeding and mangled upon the ground; but the reality never came; and by some strangely unaccountable way I could be seen a moment after on her back, up the road. As a moral, I would advise inexperienced horsemen to be careful with Mexican ponies around the apiary. ERNEST.

PUTTING HONEY AMONG THE BEES, WHEN THERE IS NONE COMING IN.

Pa has one hive of nice Italian bees. I think they are very pretty. We put some honey around the bees, but they were not working much that day. When we put the honey out there you could see the Italian bees begin to come first. VICTOR COX.

Chocowinity, N. C.

Placing honey among the bees after the honey-flow, is a little risky. It would very likely start robbing, then you would have no end of trouble. So you think the Italians will more quickly scent the sweet, than the black bees, do you? ERNEST.

WHO ARE CADDIE AND ERNEST?

Please may I ask who Caddie and Ernest are? I don't believe I ever heard who they are. My father has but one stand of bees. They are Italians, but he is going to get some more. My brother has some very nice chickens, and he is going to raise more next summer. I got a letter from Nellie Rosister. CLARA MADSON.

West Branch, Ia., Nov. 13, 1885.

Why, of course you shall know; but I kind o' hate to talk about myself, because it would hardly be the proper thing. However, I will say that Ernest and Caddie are a brother and sister of Huber. Huber, you

know, is an "off-sprig" from the old "Root." Perhaps I should say further, that I have been away to school for the last four years, and in consequence you have not heard from me much during the time. Caddie is a blue eyes, next older than Huber.

ERNEST.

DO GRASSHOPPERS EXTRACT THE SWEETS FROM THE FLOWERS?

This is my first letter to GLEANINGS. Ma has 64 colonies of bees, and sister Maud has three stands. We did not get very much honey this year. Ma thinks it is because there were so many grasshoppers. She thinks they sucked all the sweets out of flowers. They nearly destroyed some meadows, and some fields of corn had hardly a silk left on the ears.

HAMILTON DUNCAN.

Limeville, Iowa, Nov. 9, 1885.

FROM 145 TO 215, AND 7000 LBS. OF HONEY.

We have 215 hives of bees. My brother does nothing but attend to them. I help to make cushions of wool to keep them warm in winter. My brother thinks that is the best way to protect them. I also help to clean sections and crate them. We did not lose many bees last winter. Our bees did not do as well this summer as other years. We got only about 7000 lbs. from 145 stocks, and increased to 215. My pa takes all the bee-papers, but I read only GLEANINGS.

NELLIE CORNEIL, age 13.

Lindsay, Ont., Can.

BRINGING A SWARM DOWN BY WATER.

Friend Ernest:—Seeing you have charge of the Juvenile Department, I will try writing once more. Pa had six colonies of bees in the spring, and increased to 15. We extracted 242 lbs. of honey. We did not get any comb honey. Pa has his bees packed in chaff hives. Last summer our bees swarmed and were going away. I saw them, and told pa. We ran after them with water, and brought them down by throwing water on them. They alighted on a cornstalk in the middle of the cornfield.

CORA BURTON, age 13.

Goodwine, Ills., Nov. 23, 1885.

AN INTELLIGENT CAT.

I do not think there is any thing about bees that I could tell you, that you do not know already; but I am much interested in the children's letters in GLEANINGS. We have your picture in the A B C book, so that I feel quite acquainted with you. My mother has six stands of beautiful bees; they are packed with chaff cushions at the sides and on top, and we hope they will winter well. We have a white cat that is intelligent and musical. Whenever the parlor door is open he jumps up on the piano-stool and plays first with one paw, then steps on the keys, up and down the keyboard. His eyes fairly laugh with the fun. When mamma plays, he goes up on the top of the piano, and sits looking in her face, and purrs as loud as he can.

I think you are very kind to print the letters from the children. I am going to try to get you some new subscribers. FRANK BREWSTER, age 10.

Pequannock, N. J., Nov. 23, 1885.

CATCHING A 2-LB. PICKEREL.

I have been so interested in your accounts of your carp-pond that I think I will tell you about our fish-pond. It is situated about one hundred feet from the Pequannock River, and there is a brook of nice clean water running from the pond to

the river, all the year round. A few weeks since I went down there early in the morning and saw a large pickerel going slowly up the brook from the river to the pond. The water was so shallow that its back was out of the water. I caught it in my hands. It fought well and escaped twice, but finally I brought it home. It weighed over two pounds.

There are pike, pickerel, sunfish, suckers, black bass, and white fish in the river, but only a few go up to the pond. I get quite a string of fish sometimes, by using a hook and line. Nets are not allowed in the river. There is a fine of \$25.00 for putting a net in the river.

BERT R. BREWSTER, age 11.

Pequannock, N. J., Nov. 23, 1885.

POLLEN AND ITS CHARACTERISTIC COLOR, AS GIVEN BY THE VARIOUS FLOWERS.

I will tell what I think I know about pollen. On corn and ragweed it is light green; buckeye, very dark red; red clover, dark green; basswood, yellow; maple, red; hollyhock, white; elm, light yellow; thistle, light yellow; pumpkin, yellow, almost white; locust, light yellow; goldenrod, dark yellow. I got the scissors and Bible that I sent for, and I was very much pleased with them.

Woodstock, O. NETTIE H. CRANSTON, age 11.

Friend Nettie, your letter deserves a chromo too. I wonder how many of the big bee-men can tell the source of the pollen, from its color. I think it would puzzle a good many to do as well as you have done.

ERNEST.

ANOTHER RUNAWAY, IN WHICH FIVE HIVES ARE KNOCKED OVER.

My papa is a bee-man. He began two years ago, with ten swarms. He has 31 swarms now, and got about 1500 lbs. of honey. Nov. 8th there was a runaway which went through his apiary and knocked down five hives. The combs of four of them were mashed nearly all to pieces.

Last summer I watched the bees while papa was at work in the garden. Once when the bees were swarming I held the hiving-box, covered with bees, for him. I have a friend, Cora, with whom I go to school, and play.

ETHEL F. WILCOX.

Northfield, Minn., Nov. 18, 1885.

Why, friend Ethel, your experience of a runaway horse through the apiary was quite similar to the one we had. You say the combs of four of the hives were "mashed nearly all to pieces." From this I infer that you do not have your combs wired, as we do in our apiary. During the recent mishap of which I told you on page 765, scarcely a comb was broken. We should be glad of more facts as to how the bees behaved, and the cause of the accident. Friend Miller, page 811, tells us how to quiet horses that have been stung. We should be glad of more reports of this kind.

ERNEST.

A SAD STORY; JUST REWARD FOR STEALING BEES.

I have a sad story to tell you. Two young men stole a good stand of bees from pa one night, 2½ years ago, but we did not find it out then. One of the same boys and two other ones broke into a store this summer, and took a lot of goods. Two of them were sent to prison a few days ago, and one of them got away from the jailor. They may get him yet. They all live in this little town, and have mothers living, who cried about them; but the men took them any way. Pa and I went by the jail. I saw

the big iron bars. It looks as if it were built to keep wild beasts in. I want to be a good boy, and not get drunk and steal, and grieve ma's life, as those boys did theirs. I have one stand of bees, and got 126 lbs. of extracted honey from it. Pa had 11 in the spring; has 70 now. I have a big pig.

Georgetown, Ill. SAMMY LINDLEY.

SUDDEN DEATH OF A COLONY FROM FEEDING.

One of our neighbors fed dark syrup to a stand of bees at 11 o'clock, and at 12 they were all dead.

Ferndale, Cal. GEORGIE SPAULDING, age 9.

HONEY NOT FIT TO EAT.

One of our neighbors had a lot of bees, and they made beautiful white clear honey; but when they took out the honey they could not eat it. It was made of laurel and wormwood and fennel.

Ferndale, Cal. MAGGIE SPAULDING, age 11.

A KIND WORD FOR GLEANINGS.

I will write to you, and tell you something about our bees. We have about 200 hives of bees. We got about 8000 or 9000 lbs. of honey this year. Papa takes GLEANINGS, and he says he couldn't get along without it.

ADA MCPHAIL,
Gallinas, Texas.

THE LOSS OF TWO COLONIES.

Pa put two colonies of bees in the cellar in the fall, and they were looking well until lately he looked at them and found them all dead. They had plenty to eat, but it was too wet for them. It wouldn't be such a loss if there were any more bees near here. These two colonies cost at least \$25.00. If any of the readers of GLEANINGS are dealers in fruit-tree seeds, please send price list of seeds, especially Russian mulberry, grapes, plums, and crab-apples.

The bee, the bee, the busy bee,
Gathers honey off flower and tree.
He toils and toils the livelong day,
But never has he a word to say.
When the sun is far in the west,
Not the bee doth stop to rest.
Never doth he taste of rum,
Nor does he get drunk, as some.

Ellensburg, W. T. J. D. SEATON.

WHAT BEES DO WHEN THEY GET DOWN LITTLE BOYS' BACKS.

I have got my ma to write for me, for I can't write, but I like bees. I like to watch them gather honey, and to see them go in the hive with their legs loaded with pollen. My pa's bees came out one day this winter, and I was out to see them, and there were two got down my back and stung me. I have been through my First Reader once, and going through it again. I have one pet, and that is a cat.

Cameron, Pa. EARNEST WYKOFF.

"THROWING GROUND" TO BRING DOWN A SWARM; HOW A JUVENILE MANAGED.

In 1883 pa and I went in the lot to cultivate potatoes. We then saw a swarm of bees flying over us. We ran after them till we got past them. We threw ground amongst them till they clustered on a little bush. Pa told me to watch them while he went home to get a hive; and while he was gone the bush got heavy and bent down, and the bees dropped off. They commenced to fly. I was afraid they were going off, so I covered them with my hat; and they all clustered in it. When pa came he just shook them in the hive, and then we left it there till night. Then pa and brother John went and got them.

Indian River, N. Y.

MICHAEL ZEHR, age 14.

KING-BIRDS KILLING BEES; CATCHING BUMBLE-BEES.

My father had 18 swarms of bees last fall. Two of them died this winter. One of them had no queen. The king-birds would come and eat the bees last summer, but George and I would shoot them when we got a chance. Sometimes they will stay up on the tall trees, but sometimes they will come down. George, my younger brother, used to catch bumble-bees and shut them up in a hive, but they would not stay. There are lots of wild ducks that come in the pond, and we boys stone them.

Cameron, Pa. WILLIE WYKOFF, age 13.

CUT STRAW AND SAWDUST FOR PACKING; HOW TO TELL RIGHT SIDE UP OF SECTIONS.

Papa has 120 swarms of bees, packed with cut straw and sawdust, on their summer stands. He got about 5000 lbs. of comb honey and a good deal of extracted that we did not weigh. You can always tell which is the right side up of a section of honey; for unless the sections are turned over on the hive, the bees always leave the largest holes in the lower corners.

LUCY HURLBUT, age 9.
West Bethany, N. Y.

A SELF-MADE MARTYR; A BEE LIVED JUST FOUR HOURS AND A HALF AFTER HAVING STUNG.

Seeing that you had proposed to the juveniles the plan of removing the sting from a bee, to see how long he would live without a sting, I was so much pleased with the idea that I at once tried it. I went out into the apiary, and attempted to catch a bee; but just before I could capture one, a little fellow that had been buzzing unpleasantly near my ear concluded to be accommodating and save me the trouble of catching one of his companions; so he flew at me with an angry "whiz," and popped his sting into my hand. Of course, his fate was sealed, so I caught him and put him into a queen-cage, and then put the cage on top of the combs in the hive. Before putting the cage in the hive, I put a few drops of honey in it. I put the bee in at half-past eleven o'clock A. M. and he lived until four o'clock P. M., so you see the poor little fellow lived only four hours and a half. I hope some of the other juveniles will try the experiment.

Our bees have done exceedingly well this year. Papa ordered a lot of iron-jacket cans, to put his honey in. He received them the other day. He gets all of his apiarian supplies from you.

FLORENCE BOLES.

Church Hill, Miss., Nov. 17, 1885.

Well done, little friend. I am going to tell our mailing clerk to send you a large and beautiful chromo, which will be in addition to the book already sent you.—So you really are a self-made martyr to the cause of science. I wonder if that little bee, when he stung you, knew he was going to die; if he did, don't you think he was a martyr also to his dear little home? Or do you think he was just like little folks sometimes are, when they feel a little mad and want to give somebody a "dab"?—Your bee lived four hours and a half. Hulda Myers' (page 791) lived seven hours. Now let us have quite a number of reports upon this point, until we shall have this matter settled. To every juvenile who gives an answer to the problems I gave in Oct. 15, page 711, we will send a nice present.

ERNEST.

30 SWARMS AND 1200 LBS. OF HONEY.

My pa has 30 hives of bees, and he got 1200 lbs. of honey, and thinks he could have got 2000 lbs. if he had had time to take it. Pa thinks rape is nice for bees in the fall, as it blossoms, and bees work on it, until snow comes. Pa once buried a swarm of bees like potatoes, with straw six inches thick all around them, and some dirt over, and the snow drifted over them two feet deep, and in four months he took them out and they were flying all around him before he could get them out.

BESSIE GREEN, age 8.

Montague, Mich., Nov. 30, 1885.

A LITTLE BROTHER WHO CALLS HIMSELF A. I. ROOT.

My papa has 11 stands of bees; he keeps them in the front yard. I like to help him. Mamma has one stand of bees. My little brother calls himself A. I. Root. When he gets stung it knocks out some of his self-conceit. I am going to school. I have one pet pig.

—, age 9.

Concordia, Ky.

Give my respects to my little namesake, my little friend; but, what do you call *yourself*? I am glad that your brother thinks enough of me to wish to be named after me.

A LETTER FROM A LITTLE GIRL IN ENGLAND: PHENOL FOR CURING FOUL BROOD.

I have been thinking of writing to you for a long time, and now intend doing so. I need not tell you that father keeps bees. I suppose you know he does. He can not understand how it is you do not say anything about the new cure for foul brood. It is called phenol. He has sold a lot, and customers say it soon cures the complaint. He sent some to Mr. Robert Lees, Lucknow, Ontario, whose bees were very bad with the disease. Perhaps you can find out whether he did any good with it. Have you seen Mr. Cheshire's new book? Father says he will post it monthly for you, if you like.

JESSIE HOLLANDS, age 11.

The Apiary, Waddon, Croydon, Surrey, Eng.

Thank you, Jessie, for your kind letter and inquiries. I have touched upon the phenol remedy several times; but so many remedies have been proposed and afterward dropped during the past years that this matter has been before us, that I hope you will excuse me for being a little slow about recommending these new things. Besides, we have had some reports already, if I am not mistaken, saying that phenol did not answer, even when used exactly according to directions. We should be very glad indeed to have Mr. Robert Lees' report. We have seen Mr. Cheshire's book, and you will find a report of it on another page.

FROM 16 TO 65, AND 3000 LBS. OF COMB HONEY.

My pa had 165 colonies of bees a year ago, and they all died in the winter but 16; he now has 65 good ones and has 3000 lbs. of honey in 2-lb. sections. This year he raised his queens too, in little bits of hives he called mine. Pa has gone to Nebraska with 1200 lbs. of honey. He went in a covered wagon, with a four-horse team. Pa will be surprised to see my letter in GLEANINGS. This is my first letter.

BIRDIE NEEDELS, age 7.

Alanthus, Mo., Nov. 18, 1885.

Thank you for your report, friend Birdie. Your letter teaches at least one good thing;

namely, that we must never get discouraged. If we get into Blasted Hopes one year, we stand a good chance of getting out again. Your papa certainly did well to average nearly 200 lbs. of honey, besides the increase and raising his own queens.

ERNEST.

MORE ABOUT RATTLESNAKE APIARY.

After my last letter I thought I would not write again, as others write more interestingly; but your postal of Oct. 26 was a surprise and joy to me. I hope you may live many years to gladden the hearts of both adults and juveniles. We had a killing frost Nov. 28th; bees were bringing in pollen up to that date. Pa has turned the bees over to me. He said he would not have time next year to bother with them. I am going to school, and will continue to go until swarming time, April 1. My bees will not need any more attention until that time.

I went with my pa to Rattlesnake Apiary one day last week, and prepared our bees for winter by contracting the entrances and taking off one of the supers, leaving them in two-story hives, the lower story full of natural stores, with some in supers. I don't like to winter in a two-story hive. On warm days the bees go into the super, looking after the treasures there. They are either unable or unwilling to return to the cluster when the weather turns cold, and are chilled to death. The first warm day after each cold spell last winter I noticed a handful of dead bees in front of all strong colonies. By looking in the hives I found they chilled between the combs in the supers. How is it to be avoided? How shall we winter in this latitude—36°? How are we to take care of so many empty combs, without the help of the bees to clean them up during warm spells? Our home apiary, which I will call Jones-Prairie Apiary, did not do much this year. It increased from 45 to 64, and we extracted 1947 lbs. They are in fine condition. The lower story has ten full frames, with more than 1000 lbs. of nice comb honey in supers. Those that have not forgotten my report from Rattlesnake Apiary probably wish to know why 20 weak colonies, spring count, produced so much more honey than 45 strong ones. The two localities are within eight miles of each other, yet the soil and growth are as different as if they were 500 miles apart. Jones-Prairie is a gray sand, nearly all of it cultivated in corn and cotton. The country east of us for three miles to the Brazos River is a sandy timbered country. More than a thousand acres are cultivated in cotton in bee-range of our Jones-Prairie Apiary. We have never had any honey from it. I don't think cotton as a honey-plant amounts to much.

SAM. H. TERRAL.

Jones-Prairie, Tex., Dec. 1, 1885.

Friend Samuel, I do not think I would contract the entrances for winter—certainly not in your locality; and if I left combs in the upper story at all, I would fix it so the bees could not get up on to them. This, however, may not be necessary where the upper story is close, so the bees will not try to get out where they see light shining through, instead of going down through the entrance. Sometimes very strong colonies cluster partly on the lower combs and partly on the upper. In that case I should think it would do no harm. I should not think there ought to be much trouble in wintering, in any region where cotton is raised.

OUR HOMES.

Thy kingdom come. Thy will be done on earth, as it is in heaven.—MATT. 6:10.

DID it ever occur to you, dear friends, that the first petition in the prayer which our Savior gave us is, that God's kingdom may rule on earth as it rules in heaven? And as we have God's promise that our prayers shall be answered, it is certainly true that the time shall come when his will *will* be done on earth as it is in heaven. Well, is this to come about all at once, like the shock of an earthquake, or is it to be brought about by the progress of human intelligence, and by the Spirit of God moving in the hearts of men? Unquestionably, the latter way; and one who does not see evidences of the coming of this kingdom, even now at this present day, must be dull indeed.

I have just returned from the convention at Detroit, and the thoughts I have just been giving you were called forth by this national gathering. The matter first came up on the cars, in talking with a commercial traveler. Like too many others of his class, he was inclined to ridicule Christians and the Christian religion. I don't believe much in argument, as you know, especially in controversies in a public place; and although I replied to him quietly and carefully, I did not hesitate to let him know that I was a follower of Christ. As he left me he replied that it would be a glorious thing, without question, if Christians would only *hold out*, and not forget their profession and their religion. I had been answering him with texts; and my parting word was the admonition, that only "he that endureth to the end shall be saved." He smiled as I looked him full in the face while I gave him my answer, and apparently he opened his mouth to reply; but catching the glance of a passenger in the next seat, there was a little general laugh all around, and he evidently thought he might as well give it up. The Bible is equal to every and all emergencies; and if one follows its precepts, there is no danger of one getting around it or avoiding its conclusions. While talking, a nice-looking young man about the age of Ernest came up and asked if he had the pleasure of speaking with A. I. Root. As I smilingly nodded, I extended him my hand. He is a reader of GLEANINGS, and lives in Lancaster Co., Pa., and he is an earnest Christian. How I do love to see young men who are not afraid to acknowledge the Savior! We roomed together that night and the next. My acquaintance with him strengthened my faith in the idea embodied in our text. That glad time is coming; and, oh what a help these vigorous young hearts are going to be in bringing it along! The next morning I met a couple of bee-friends whom I fear have little or no faith in God, and, as a matter of course, not much in their fellow-men. What a sad, sad thing it is to lose faith in humanity, and to decide that the world is *all* hollow and deceitful!

When we reached the convention we found the hall filled, and the members seem-

ed to be in the midst of an animated discussion. That I might not interrupt, I quietly slipped into a seat by the door, proposing to go forward when there was a better opportunity. Somebody near the speaker's stand, however, caught sight of me and motioned me forward. There were Bro. Jones, Bro. Newman, of the *A. B. J.*, W. F. Clarke, friend W. Z. Hutchinson, friend Heddon, and good old father Langstroth besides. Mr. L. C. Root, of New York, whom I had never seen before, occupied the president's chair, while roundabout were the friends whom we have heard from through the journals, and read about for years. Scarcely a face was missing, unless it was that of Dr. C. C. Miller. Pretty soon W. F. Clarke stood up with a large paper box in his hand; and what do you think were my feelings when he spoke something as follows?

"Mr. A. I. Root will please stand up here before me and look me in the face."

I suppose you have heard, or had experience, of the way in which people think of a great many things while they are falling from a building, or during some great danger. Well, while I was rising to my feet and obeying orders, I thought of a great many things. I inventoried, as it were, all that I had been guilty of, to see whether there was any thing there that I might fear to have brought to light. Well, although I am bad enough as it is, I could not think of any thing that should warrant calling me up in this way for a public reprimand; so I concluded (while I inwardly thanked God that no guilty secrets lurked within my soul) that friend Clarke's "medicine" certainly could not be any thing very bad to take. Now, I can not remember what his address was, only that it was in substance something like the following:

"Bro. A. I. Root, we, the bee-keepers of North America, in recognition of your services during the years that are gone by, not only in laboring for our temporal good, but in view of the energy and zeal with which you have toiled for our spiritual good as well, do hereby tender you this beautiful book. Now, dear brother, while we say this, remember, please, we do not all of us indorse all of your peculiar doctrines, neither do we think exactly as you do on many points; but for all that, we know you have worked honestly and faithfully and unselfishly; and in view of this we take pleasure in handing to you this small testimonial of our esteem and friendship. Take it; and may God spare you to work with us for many years yet to come."

As he took his seat, he indicated, in a lower tone, that I was expected to make a speech. Now I want to say, by way of parenthesis, that, a few weeks ago, I was called upon to tell my story about Mammoth Cave, in our neighboring town of Akron, Summit Co., O. It was at a large Sunday-school convention, and of course the papers advertised me pretty well, and I had a large church pretty well filled, for an audience. The next day, the papers, in reporting a part of my talk, made the remark that "Mr. Root told the truth when he said at the outset, that he was not much of a speaker."

They did say, however, that I gave them a very pleasant conversational account of the wonders of Mammoth Cave. Well, I am afraid the friends at the National Convention thought I was not much of a speaker; but I guess they gave me credit for being honest, just as the newspaper reporter did.

I wish I could tell you what was said and done during the convention during that day, but it is utterly out of the question. The reports of the papers read, you will doubtless see. But no pen can picture the pleasant, hearty good feeling that pervaded the convention; and above all, the kindness and broad charity for each other, even in our differences, that seemed to be the prevailing spirit through it all. We went there with our hobbies, a great many of us, and we got laughed at; but we were laughed at so good naturedly, that grace was given us to laugh back again. W. F. Clarke had his hibernating-box there on the stand, and friend Heddon had his pollen theory along with him. D. A. Jones had his wonderful stock of dry jokes ready to crop out when an opening gave even half a chance. Mr. J. B. Hall, of Woodstock, Ontario, kept us roaring with his grotesque oddities, and Prof. Cook rose up once in a while (in fact, I was sorry he did not rise up oftener) and give us wise counsels and wise suggestions; and Prof. Cook has such a kind, neighborly way of telling these suggestions, or even calling us back to the right track, that no one can ever for a moment think of feeling hurt at any thing he says.

Friend Muth was there too, towering above the rest of us, and making us all feel pleasant just to look on his genial face while he read an article on the sale of extracted honey. I for one was surprised to learn that they are now using honey largely for packing and curing pork; and friend Muth stated that he had filled one order for 100 barrels, to be used solely for this purpose, besides numerous smaller orders; so you see another avenue is opening for the sale of honey. Honey has the property of answering even better than any grade of molasses that can be bought at any thing near the price.

In shaking hands with the different friends at the noon intermission, I asked one great stalwart chap his name, and he just laughed at me. "Why," said he, "I am G. M. Doolittle; and although I stayed once with you three or four days, you don't know me." I felt ashamed of myself, and no doubt blushed in confusion. But when there was such a sea of pleasant faces, and so many wanted to shake hands with "Bro. Root," I got sort o' mixed up, and scarcely knew anybody. Besides, that big book had scared me and astonished me, so that it all seemed somewhat unreal. By the way, I forgot to say that the book was a large illuminated edition of *Paradise Lost*, illustrated by Gustave Dore. Now, I am almost ashamed to say that I don't know what *Paradise Lost* is about very well; but I am going to commence reading it to my wife evenings.

Mr. L. C. Root, the president in the chair, I had never before met. Before the convention was over I had abundant reason to be

sorry that I had never met him; and, by the way, before the first day had passed I began to have a much higher opinion of a great many whom I met and heard from there than I ever heard before; and by some queer coincidence I began to have a smaller opinion of myself.

Neighbor Blakeslee once said it took the conceit out of him to go and visit his brother bee-keepers. Well, I shall have to admit that this convention took the conceit out of me in a great many ways. I was surprised and astonished, over and over again, at the masterly way in which one brother after another handled the subjects as they came up. Their experiences indicated that they had read and thought and practiced, and also that the deductions that they had drawn were based on much wisdom and common sense. The Bible says, "In the multitude of counselors there is safety," and I had a feeling that, with such meetings as this, the future of bee culture must be safe and sure. And then came every now and then a glimmer of the thought embodied in our text, that it is certainly a good and wise thing for men of great intellects to meet and compare notes and exchange ideas. I have before had strange convictions that these meetings were going to result in pleasanter feelings between the North and the South, and the East and the West, and between people of different nations and different ideas, and that through such meetings the glad millennium was to be hastened—the time when God's kingdom should come, and his will be done on earth as it is in heaven.

The number in attendance at the Antisdel Hotel was so great as to fill it to overflowing, and every room was alive with buzzing voices. It seemed like one great family reunion. The waiters eyed us a little curiously, and the newspaper men evidently didn't quite know what to make of us. In the *Evening News* of Dec. 9, appeared the following little item, which, although probably greatly exaggerated, I think has enough truth in it to cause our hearts to rejoice, and to indicate again that the promise in our text is surely coming. Here is the item:

"The bee-keepers seem to absorb something of the traditional virtues of the insect they cultivate. Those attending the convention now in session in this city stop at a temperance hotel, seldom indulge in the dissipation of a theatrical entertainment, retire early, and are strangers to the fascinations of the weed. The boy who keeps the cigar-stand at the Antisdel house, to a remark about trade, replied, 'I've sold only one cigar to the whole bee-keeping gang, and that was a five-center.'"

In the morning I was up as usual at half-past five. The clerk inquired if bee-keepers always got up at that time in the morning. I told him I did for one, and asked him if he could give me the address of the largest greenhouses in the city, and whether any of them were devoted to raising vegetables. He could not answer me directly, but by the aid of the directory he gave me some points to look up. I was the first one to go into the breakfast-room. Breakfast over, I hied for the greenhouses. The air was bright and frosty, and the half-mile walk soon made me happy. I found a beautiful greenhouse, but it was all flowers. I would very

willingly have given four dollars for an azalea growing in a small pot, were it possible for me to have got it home without injury. Were there *ever* such poinsettias, japonicas, and camelias before? The proprietor was engaged in fixing a basket of exotic flowers, intertwined with smilax, while he talked with me. May be such collections of beauties have been in sight where I was around before, but I can't remember it. One greenhouse was devoted to orchids; and even these odd-looking things had a beauty that morning that I had never seen in them before. Do you want to know why every thing seemed to be speaking of God's glory, and moving me to lift my heart to him in thanksgiving and praise? Why, I had been having a *brisk walk in the open air*. Do you remember what I said about the Peck's Pleasant apple, and the California honey? That was it — brisk, health-giving exercise out in the wintry air. Following his directions I took a street-car, away over to the other side of the city, and on my way I stopped at the central market. Here I found celery on sale, away ahead of any thing our grounds had yet produced. I looked for lettuce, and finally inquired of one of the stout German women who stood by their stands, even though the weather was down toward zero. She threw a blanket from the top of a barrel, and showed me the same kind of fringed lettuce I saw in the market in Columbus, evidently raised out of doors, protected by some sort of mulch. It seemed a little strange to me that the lettuce was kept from injury by the frost, by a simple barrel and blanket. These people at the market have learned by sad experience, just to a dot, what their vegetables will bear, and I was greatly pleased to see how they managed during such a winter morning, and also to see how they succeeded in handling choice vegetables so safely.

There was nice honey on the market, and I was pleased to see some of the finest packages labeled, "From the apiary of M. H. Hunt, Bell Branch, Wayne Co., Mich." All the honey offered for sale had the name of the producer plainly printed on the package; and from appearances I should think they were having quite a trade in the genuine article. Why can't newspaper men interview the market men, and — tell the truth?

I was told in the market that there was a man by the name of George Ferguson who had a greenhouse specially devoted to raising lettuce, and that he brought the finest lettuce into the city of any man in the market. Nobody knew exactly how far away he lived, but it was somewhere between one and four miles. It was just eight o'clock, and I started a little sadly to go back without having found a greenhouse devoted to market gardening. I mentally figured this way: Street-cars will carry me six miles an hour. Mr. Ferguson is probably not more than two miles away. Perhaps I can find him and get back before the convention opens at nine o'clock. Off I started. The driver said he knew on which street Mr. Ferguson lived. It was off from the line of street-cars, but he did not know how far off. Soon I was on foot again, in the suburbs of the

city. I found the place, as I supposed, and for the first time in my life I saw nice large heads of lettuce in the middle of the month of December. They were whiter than ordinary lettuce—in fact, almost if not quite as white as nicely bleached celery, on account of the heavy manuring they received, probably, and the confinement of the greenhouse. A boy in his teens showed me through the houses, but I was somewhat dissatisfied at the want of order and system. Finally my young friend remarked, with a touching sadness, "We used to have things looking nicer before father died." I did not feel like criticising any more. If God should see fit to take me away, would that sad remark, or a similar one, be heard around my home? May God help the widows and the fatherless! Pretty soon he said that his uncle did a good deal more at lettuce than they did. His *uncle's* name was *George Ferguson*, the man I was after, so I hadn't found the place after all. His younger brother said it was probably about a mile, but the other said it was a little further. I walked a mile, and inquired. They said it was a mile yet. Another mile, and I found a man mulching spinach. This was just what I wanted to see. After he had shown me all about it, he said my destination was *still* about a mile. Shall I go back and give it up? Fifteen minutes more time, and I shall probably find what I seek. No doubt I shall find some hint worth to me at least *thirty* minutes' time, and so I pushed on, and I got my reward, not only in seeing the beautiful lettuce, but Mr. Ferguson's wife told me that he had more orders at \$1.75 per bushel than he could possibly fill. In fact, he had gone to town now with a load hardly large enough to cut. She said, that the day before Thanksgiving he could easily have sold *forty* bushels at \$2.00 a bushel; and yet a few years ago people wouldn't buy it at all in December. The demand for such stuff is of recent date. I will tell you what else I saw. Adjoining one of the greenhouses was a warm light room for poultry. Old Izaak Walton once remarked, "Doubtless God *could* have made a better berry than the strawberry, but *doubtless* he never did." I felt like saying, "Doubtless God *might* have made a handsomer flock of Light Brahmas" than my friend the old German woman exhibited to my admiring gaze; but it seemed to me "doubtful whether God ever did" make another flock as handsome. They were cackling and singing, and laying eggs, apparently oblivious of the fact that it was the middle of December and not May. But, weren't they beauties?—spotlessly clean, covered with soft down, and of immense size, with grace and symmetry in every motion, and that kind, neighborly look (if it is proper to say a hen can have a *neighborly* look) that is so characteristic of the Light Brahmas. Do you wonder why they gave me such pleasure, that keen, frosty morning? Why, I had got loose in the fields, and had been walking briskly two or three miles across lots, climbing fences, studying God's wonders, and loving his creatures.

There was one thing about their greenhouses where I think I could have made an improvement, in raising lettuce at least.

The plants were not accurately spaced, and they did not economize the ground under the glass, when that ground was so extremely valuable. Some of the plants were nearly a foot apart, others perhaps two inches; and when plants were pulled up for market, the ground was not *at once* prepared, and more plants set out, as we do it in our green-houses. But my mission of the morning had been accomplished; I knew just how it was done, even though I had played truant a little in being "late to school." I had also seen it demonstrated that poultry can be made to do beautifully, and lay right through the winter, by a modification of the manner in which we raise plants in the winter time. Many of the poultry-journals say that artificial heat makes fowls tender, and engenders disease. I should put it this way: Artificial heat in the hands of a slipshod manager will probably engender disease and feebleness in either plants or animals. There is no success in anything without intelligent painstaking.

The time approached for me to take the train home. I asked the president for permission to say a word or two to the friends before I left. In my brief talk I closed up with the little text at the head of this talk. I then wanted to get away as quietly as possible, that I might not disturb the interest of the meeting by going out before the regular close. But, up hopped our jolly friend Jones, and proposed a recess of five minutes so that they could all shake hands with "Bro. Root" before he went away. I persisted that it was a little too much disturbance and diversion; but his motion was carried with a good deal of merriment. Now, I had already shaken hands a good many times with almost all the bee-friends there, among them quite a number with whom unpleasantness had at some time occurred. There was one brother present who had, some time before, publicly charged me with something of which I was entirely innocent. At the time he did it I wrote to him, giving him full proof of his mistake, asking him to correct it as publicly. He had never done it. Of course, I did not feel very much like shaking hands with him while he let that unjust charge stand before the bee-keeping world. While the rest were shaking hands with me before my departure, he came up too and put out his hand. I remembered at once that he had not yet recalled his untruthful accusation, but I quickly decided that it did not matter (so far as concerns *myself*) even if he never did. I had just had proof that I had as many friends — yes, a good many more, than I deserve; and what does it matter, even if *some* people do believe me greedy and unprincipled? There are plenty of others who do not. I put out my hand as pleasantly as I ever did, and gave him a hearty "God bless you, friend Blank." Now, I did not mean by this that I wished that God would prosper him in doing wrong, but I did mean that I wished that God would prosper him in all praiseworthy undertakings. My friend, did you ever pass through a similar experience?

At night I arrived at Elyria; and as I was tired and sleepy I turned eagerly toward

the first hotel in sight. After I had asked for accommodations I discovered that one-half of the hotel was a beer-saloon, and a rather hard place for a Christian at that. What should I do? Why, put up with it, and do all I could to bring about "thy kingdom come," etc. Before lying down as usual, I knelt and prayed for those I had left; and I not only prayed for the bee-keepers, and for the editors of all the bee-journals, but I prayed for the saloon-keepers as well; and before my head had touched the pillow I was astonished to find a great flood of happiness and peace pouring into my soul, and the feeling I have often mentioned before, as though invisible friends were all round about me. It was not very strange, after all. I had fought against my natural temptations, and had allowed the spirit of Christ to triumph; and suddenly there came into my mind the words of the old hymn, that I always like at such times. I began to sing the first lines, and was a little surprised to find that the words came sharp and clear to my memory, so I sang the verse all through:

Know, my soul, thy full salvation;
Rise o'er sin and fear and care;
Joy to find, in every station,
Something still to do or bear.
Think what Spirit dwells within thee;
Think what Father's smiles are thine;
Think that Jesus died to win thee;
Child of heaven, canst thou repine?

Then came delicious, health-giving sleep; and as I sank into unconsciousness it seemed to me as it never had before, perhaps, that he who has God for a friend has nothing to fear, either in life or in death.

Dear reader, these are my last words to you at the close of the year 1885. I thank you for having followed me in my humble efforts thus far; and may the blessing that only God the Father can give to his children be your portion!

EDITORIAL.

The mountains and the hills shall break forth before you into singing, and all the trees of the field shall clap their hands. — ISAIAH 55: 12.

HOW DEEP SHOULD WE PUT OUR SUB-EARTH VENTILATORS?

It depends on what we want the warm air for, I think. For a cellar for wintering bees, perhaps three or four feet is all that is necessary. If we want warm air for a cold frame to grow hardy plants, perhaps we shall need to go as deep as eight or ten feet, to get the best results; but I hardly think the temperature is higher at from 40 to 100 feet in the earth than it is down 8 or 10 feet.

SWARMING OUT IN DECEMBER.

THEY left the old hive and went as far as a quarter of a mile. It is true, the parent stock suffered some depletion, but yet there is quite a goodly number left yet. It was not bees that swarmed out, and it was not the queen, but it was the queen-clerk Lizzie, and Ernest went along with her, to start a new home. The happy couple are just now on their way to visit friends in the east; but they expect to be back in a few days, and take up their permanent abode within about a fourth of a mile of the paternal mansion, as before mentioned.

EDITORIAL.

BEES AND BEE-KEEPING.

We have lately received a few advance copies of "Bees and Bee-keeping," by Frank Cheshire, England. The work is to be completed in 19 parts. As a treatise on the physiology and anatomy of the bee, it probably stands at the head. The engravings are very fine—a copy of one of which, with a few slight modifications, is seen in another column. So far as we have been able to notice, the writer seems to be not only a skilled microscopist but a careful observer.

ERNEST.

AN EXPERT BEE-KEEPER IN THE EMPLOY OF THE UNITED STATES.

ONE of the many treats to which we listened at the Detroit Convention was the papers from Prof. McLain, whom we have before mentioned as employed by the Government to treat disputed matters in bee culture. A very elaborate experiment was made to ascertain whether bees can puncture grapes. Not only were grapes innumerable provided, but many colonies of bees. The decision was in the negative. We are pleased to mention that friend McLain has also succeeded in fertilizing queens by mechanical means. It is true, this has been accomplished before; but the professor will probably soon be able to give directions so that any ordinary bee keeper can manage the process with but little risk of failure. We have reason to feel thankful toward the United States for having furnished the means for such experiments; and we also rejoice that they have secured the services of so able a man. He promises to furnish articles for the different bee-journals in due season.

FOR SALE CHEAP.

All kinds of Fruit-trees, Vines, Raspberry-bushes, black or red; Basswood, Hard Maples, Mountain-ash trees. Please write for prices. Address
H. WIRTH, BOROINO, ONONDAGA CO., N. Y.

100 Scroll-Saw Designs, 10 CENTS.
Hundreds and samples of Xmas Cards, 10 cents.
24d **J. L. HYDE, Pomfret Landing, Ct.**

SIMPLICITY HIVES, 42½ CENTS.
DOUBLE-STORY LANGSTROTH, 90 CENTS.
UNTIL MAY 1, 1886.

Young Poplar-trees, 70 cents per 100, sent postpaid by mail. **T. A. GUNN, Tullahoma, Tenn.**

WANTED.—Situation on salary or shares from some bee-keeper. Have had 7 years' experience. **E. SANDFORD, Nokomis, Ill.**

NEWFOUNDLAND PUPS

For sale, \$10.00 apiece. Beautiful little fellows—children's best friend in times of trouble. Address 3, 24, Id. **A. J. NORRIS, CEDAR FALLS, IOWA.**

AGENTS WANTED

In every township to sell one of the most valuable implements out. Every farmer needs it; now is your time to make some money.

J. G. GRAY, Medina, Ohio.

23, 24, Id. Mention this paper.

DADANT'S FOUNDATION FACTORY, WHOLESALE AND RETAIL. See advertisement in another column.

UNTESTED QUEENS READY FOR SHIPMENT

I have at this date ¼ dozen untested Italian queens, ready for return mail at \$1.00 each. Safe arrival guaranteed. **L. W. GRAY, Orlando, Fla.**
